When considering the issue of protection and prevention of disease, differences must be considered between the objectives and parameters of public health and "private health" (clinical medicine). In the former, the stakeholder is society or a community; in the latter, it is an individual. Public health sets as a goal prevention of diseases by promoting healthful conditions such as the environment and group behavior for the community at large, while the objective of clinical medicine is to cure a sick individual (Laska, 1997), which may include a behavioral change on an individual level.

Radiation protection is a public health issue for a number of reasons. Health effects of radiation are not unique. Except when acute radiation exposures are involved, radiation effects in

a population can be detected only on the basis of statistics and epidemiology. Another reason for considering radiation protection to be a public health issue is that individuals have only a limited ability to structure or control their own environment (Cember, 1998).

Societal, i.e., governmental, regulation of radiation sources became a necessity to ensure that the health of the public would not be compromised by the new technology that rose from the ashes of World War II. The U.S. Atomic Energy Commission (AEC), created by the Atomic Energy Act adopted by the U.S. Congress in 1946, acquired broad authority to regulate nuclear reactors and the use of “byproducts,” radioactive materials resulting from the operation of the reactors (Cember, 1998). At the international level, as applications of nuclear technology developed and became worldwide, the International Atomic Energy Agency (IAEA), a specialized agency within the United Nations (UN), was formed in 1956.

The U.S. NRC was established as an independent federal agency by the Energy Reorganization Act of 1974. A description of NRC’s mission can be found in its 1997–2002 Strategic Plan. It reflects the ICRP philosophy:

NRC’s mission is to regulate the Nation’s civilian use of byproduct, source, and special nuclear materials to ensure adequate protection of the public health and safety, to promote the common defense and security, and to protect the environment (Jones and Raddatz, 1998).

NRC has an extensive web site containing full text of press releases, summaries of proposed and final rules, and other relevant information (www.nrc.org). NRC’s mission is reflected in the Agreement States’ radiation safety programs that control most uses of byproduct material. Nuclear reactors, federal facilities such as Veterans Administration hospitals and army bases, and facilities distributing exempt quantities of byproduct material are some examples of uses that remain under the NRC jurisdiction. The Conference of Radiation Control Program Directors (CRCPD) established in 1968 serves as a common forum for state radiation control programs.

Good radiation safety programs at the licensee level must be well balanced among engineered safety and personnel training, considering technical, scientific, economic, human and ethical aspects of radiation use. Written policies and procedures based on applicable regulations, endorsed by the management and major users are at the core of a successful program.

Integrated Radiation Safety Program: Organization and Structure

The medical radiation safety program must adequately protect patients, care givers, visitors, and the general public. Its development, implementation, and maintenance are grounded in cooperation on all administrative levels, efficient coordination of efforts, and excellent communications.

Management

In a medical facility, regardless of size, management is ultimately responsible for the success or failure of the radiation safety program. Management might consist of a senior-level administrator or a team of administrators in a large organization, or it might be limited to a radiologist or owner in a small independent practice (Vetter, 1998). In its excellent treatment of management of medical programs, the NRC has developed the concept of a management triangle to emphasize three responsible entities: executive management, the Radiation Safety Officer (RSO), and the Radiation Safety Committee (RSC) (USNRC, 1997). There is clear expectation that executive management will rely on the RSC and the RSO for day-to-day operation but that it might not delegate ultimate responsibility for the program.

The Radiation Safety Committee (RSC)

The U.S. NRC and Agreement States require medical institutions to establish a Radiation Safety Committee (RSC). In facilities that include inpatient care, the executive management appoints membership in the RSC. The committee should represent a cross section of medical use areas and expertise. The NCR requires that membership include the RSO, an administrator who has the authority to commit resources, a nurse, and representatives from each major area that utilizes radioactive materials, such as nuclear medicine or diagnostic radiology, radiation oncology, cardiology, and clinical research (USNRC, 1997). The RSC is charged with overseeing, with the assistance of the RSO, uses of all radioactive materials and machine produced radiation. In some cases, this entity oversees the sources and uses of non-ionizing radiation, as well. The RSC should have the expertise to carry out all responsibilities with which it is charged.

The RSC chair often has considerable influence over the tenor and effectiveness of the committee. The chair should be a leader as well as an expert in radiation (Vetter, 1998). The function should be rotated every few years to provide new energy and ideas. Similarly, some members of the committee should be rotated to allow for fresh support for radiation safety advocacy within the radiation user community.

While it works well in some organizations, management should be cautious about appointing the RSO to chair the RSC. The RSO is responsible for day-to-day operations and might be too busy to run the committee effectively, or might be too closely involved with licensed activities to be objective. Depending on the culture of the institution, an authorized user from a major user department (a physician), a medical physicist, or a management representative may be appointed. The selection of an authorized user has a potential of leading to a conflict of interest if a radiation safety problem develops in this person’s department. Medical physicists with leadership skills usually are effective chairs because they have considerable knowledge of the applications of radiation and the principles of radiation safety. Whether management appoints a physician or a physicist to chair the RSC, they must delegate an appropriate level of authority to support and empower the radiation safety program (Vetter, 1998).

Regulations require the RSC to meet at least quarterly and to record and maintain the minutes (Code of Federal Regulations). A typical agenda of these meetings includes: RAM license amendment requests, modifications to the program, incidents/accidents, occupational radiation doses of an institution’s personnel, radioisotopes’ inventory, approval of authorized users, review of human-use protocols, and the Radioactive Drug Research Committee (RDRC) items if the facility has an approved RDRC (FDA). In most programs, the RSO must assemble this information for the RSC and should ensure that members receive the agenda and any additional information that will facilitate efficient discussion and consensus decisions. In large, broad scope medical programs, the RSO is generally assisted by an alternate (i.e., deputy, or assistant) RSO. Such a person oversees designated elements of the program, participates in the RSC activities, and might be assigned to prepare the RSC agenda items.

The RSC and the RSO have a joint responsibility for the development, implementation, and maintenance of the radiation safety program. The committee, with RSO’s assistance, must review the entire program, including the “As Low As Reasonably Achievable” (ALARA) policy on an annual basis.

The Radiation Safety Officer (RSO)

A firm commitment to radiation safety on the part of management is a condition of licensing. The chain of command for the medical radiation safety program and designated RSO is of utmost importance. The RSO should be reporting directly to the upper level of administration as this prevents placing the RSO in a compromising position of being answerable to potential violators of good radiation safety practices (Miller, 1992). Responsibilities and the authority of the RSO should be carefully considered and explicitly expressed in writing. Access to all areas where radiation sources are used or stored must be provided. The RSO must be granted discretionary authority to terminate activities that violate established safety practices immediately and without consulting management or the RSC. Such instances require a review by management, the RSC, or both, as soon as possible. The goals of these reviews are to determine the root cause(s) of the problem, to identify effective corrective actions, to examine the program for the potential existence of a similar problem in another area, and, if possible, to authorize resumption of activities (Vetter, 1998).

The principal responsibility of the RSO is to ensure that radiation is used safely, in accordance with regulatory and accreditation requirements and approved policies and procedures which reflect those requirements. The RSO should be given the authority and responsibility to audit activities performed under the RAM license to ensure compliance with established policies and procedures.

The RSO is responsible for the implementation of a wide variety of duties and tasks that are common to specific and broad scope licenses. These duties encompass administrative, technical, clinical, and teaching areas. Listed below are some of the most essential duties.

Regulatory Activities Related to RAM License

These activities include obtaining and becoming familiar pertinent regulations, keeping abreast of regulatory changes, preparing and filing of radioactive-materials-license applications, license renewals, and amendments. Following receipt of the license, it is the RSO’s duty to ensure that license conditions and statements made in the application are adhered to. This is accomplished through the development and implementation of practical procedures, by maintaining appropriate documentation and/or development and completion of forms. These records are subject to regulatory inspection. The RSO and radiation safety representatives of areas where radioactive materials are utilized participate in internal audits and in regulatory inspections.

These activities consist of examination of procedures and representative records, measurements of radiation levels in selected areas, interviews with personnel, and/or observations. If the findings of an audit or inspection indicate existence of items of noncompliance, whether or not they are cited as violations or recommendations, these conditions must be addressed as soon as possible. Authorized users and the RSO have a joint responsibility to see that corrective actions are taken and that the possibility of recurrence is minimized.

If corrective items require unplanned expenditure or the need for other resources that are not available to the RSO, the RSO will present these items and will propose the course of action to management, the RSC, or both. Approval or disapproval (with explanation) must be documented in the RSC minutes.

Multilevel Radiation Safety Training

It is imperative that all individuals involved in the use of radiation sources receive appropriate area/modality specific training and education. Federal (5) and state regulations specify these requirements, and the NCRP Report No. 105 (NCRPM, 1989) provides general guidelines. The RSO is responsible for ensuring that authorized users have the required (Code of Federal Regulations) credentials and that other personnel receive instructions. Depending on the scope of operations, training can take on various forms, ranging from formal lecture series (live or computer-assisted), to topical in-services, to supervised viewing of videotapes followed by question-and-answer sessions. The training must be provided for all individuals who are likely to receive an occupational dose of 1 mSv (100 millirem (mrem)) in a year.

The following general topics must be included: Information on the location of sources of radiation, the basics of radiation, health effects of radiation exposure, principles of radiation protection, area-specific policies and procedures based on regulations and on scientific grounds, information on posting, and radiation safety contacts. More detailed information is provided as part of an area-/modality-specific instruction (i.e., patient and visitor restrictions for nursing staff, and operational techniques that minimize patient and personnel dose for staff participating in fluoroscopic procedures). Personnel must be instructed to report to the RSO any condition that constitutes or may lead to an unsafe situation and/or is in violation of established procedures.

Many medical procedures require specialized patient instruction. Depending on the type of procedure, the instruction may be provided by the RSO, by the physician in charge of the case, or by other trained health care personnel.

Monitoring of Occupational Radiation Doses of Personnel

Each authorized user of radioactive materials and each registrant of equipment that generates ionizing radiation is required to provide personnel monitoring devices to certain categories of individuals who could be exposed to radiation during the course of their employment. Specifically, these categories include individuals who are likely to receive a dose of radiation in excess of 10% of the appropriate permissible occupational limit and individuals who enter "High Radiation" and "Very High Radiation" Areas (Code of Federal Regulations) (Special limits are set for minors and "declared pregnant" female employees.) Various types of dosimeters are available on the market. The RSO makes a determination regarding suitability and types of dosimeters issued to individuals working in different areas. For example, collar dosimeters are appropriate for personnel who work with fluoroscopy, and finger or wrist dosimeters are issued to personnel working with radiopharmaceuticals in nuclear medicine. A number of technologies applied for this purpose include film, thermoluminescence (TLD), and optically stimulated luminescence (OLS). Whatever the choice, the provider of dosimetry service is required to hold an accreditation from the National Voluntary Laboratory Accreditation Program (NVLAP) of the National Institute of Standards and Technology (NIST).

The RSO is charged with the responsibility of tracking radiation doses of personnel and investigating all cases when these doses exceed established ALARA levels. Note that while the existence of ALARA program in a medical setting and its annual review by the RSC are mandated, the levels of doses at which an investigation and/or other action is taken are based on the judgment call by the RSC.

Control of Radioactive Materials

The RSO is responsible for establishing and maintaining a system of control wherein radioactive materials will be ordered and received only by authorized users, and in accordance with license conditions. Generally, there are one or more designated areas where the actual receipt takes place. In addition to user verification, personnel who receive radioactive materials ensure that there is no external contamination on packages.

Authorized users have the responsibility of using materials in accordance with established area-specific procedures. When not in use, radioactive materials must be safely stored in a fashion that prevents unauthorized use. It is generally advisable to keep a "running" inventory of all materials. All areas where radioactive materials are used must be surveyed to ensure that there is no removable radioactive contamination. Types and frequencies of these surveys are area specific. Transfers of radioactive materials (internal and external) can be done only with the RSO's authorization. In all cases, such transfers only can be between specifically authorized or licensed parties.

Used (spent) radioactive materials must be properly disposed of. It is the RSO's responsibility to develop and oversee a radiological waste (radwaste) management program. Except for certain long-lived isotopes (e.g., Carbon-14) utilized in clinical research, the majority of radioisotopes used in routine clinical applications fall into two categories: Short-lived isotopes used in diagnostic (i.e., Technetium-99m) and therapeutic procedures (Iodine-131), and sealed sources used for therapeutic purposes (i.e., Iridium-192). Radwaste containing long-lived isotopes is generally disposed of through the use of outside waste contractors. Disposal of radwaste containing short-lived isotopes can be accomplished through on-site DIS (decay-in-storage) method. Sealed sources that are no longer needed are generally returned to their respective suppliers. In all approaches, all materials must be accounted for; stored waste must be properly labeled (Code of Federal Regulations); and vehicles that are used to transport waste and packages containing no-longer-needed sources must meet appropriate local and federal (USDOT) criteria. The facilities where radioisotopes are no longer used must be properly decontaminated, if needed, and decommissioned under the RSO's supervision.

Active Participation in Planning of New or Remodeled Facilities

Before any structural changes are made in areas housing radioactive materials and/or radiation producing equipment, the RSO must be notified to afford the assessment of radiation-protection adequacy of the proposed changes. To facilitate this assessment, management must provide all required details to the RSO. Assessment of adequacy and correction recommendations, if deemed needed, must include the aspect of general public protection (Code of Federal Regulations). Any radiation producing equipment that is no longer in use must be disabled.

Response to and Investigation of Incidents/Accidents

All incidents that involve radiation (e.g., misadministration and occupational doses exceeding the institution's ALARA levels) must be investigated immediately. Certain instances are required to be reported to regulatory agencies within 24 hours of their occurrence (Code of Federal Regulations). In addition to making efforts to identify the cause, and to taking and recommending corrective action, the RSO must develop a plan to prevent recurrence of such incidents.

Similarly, all accidents, e.g., loss of control over radioactive materials, a patient who has been radioactively contaminated off site, and presenting in the emergency room, will require the prompt response of the RSO and/or designated radiation safety staff. In most medical facilities, radiological response is part of the overall emergency (or disaster) plan. Appropriate training and drills are necessary to test the efficacy of such plans.

Quality Management Program (QMP)

Most medical radiation safety programs require individual user departments to develop and implement a quality management Program (QMP). This approach aims at prevention of unnecessary radiation exposures and extends continuity of protection activities from

personnel and the general public to patients without infringing on physicians' rights to practice. To accomplish these tasks, management of the organization must ensure that the radiation safety program has appropriate resources.

Medical Radiation safety Program Resources and their Utilization

What is needed to run an efficient medical radiation safety program will depend upon the size and scope of the organization. However, certain generic resources are necessary for the program to function. These include the following:

1. Appropriate staffing
2. Radiation safety office
3. Health physics laboratory (or access to one in shared programs that exist at many university centers)
4. Storage and radwaste handling facility and equipment
5. Financial resources and logistical means to conduct the program

Appropriate Staffing

The designated RSO should be a medical-health physicist who has the pertinent technical and operational knowledge of the field. In small settings, a physician (i.e., a radiologist or radiation oncologist) who has experience in handling radioactive materials could be designated as an RSO on the license. This person must have appropriate credentials, specified by the federal and/or state regulations, to be accepted for this position (5). It is desirable for them to be well-organized, to have people skills, and to be a good communicator. In addition, the RSO must have (or develop) a good bedside manner, which is essential in a clinical setting.

In any size of radiation safety program, the RSO must have an appropriate backup. Such person(s) will need to be knowledgeable to fill in for the RSO in routine, as well as emergency, functions to ensure continuity of the program in all instances. Large programs have multiple assistants (i.e., deputies or alternates). In addition, the program needs technical and clerical personnel who perform clearly designated day-to-day duties. The number and level of personnel are determined by the scope of operation and the number and type of in-house services required in a particular setting.

The Radiation Safety Office

The office of the RSO is at the heart of the radiation safety program operation. It is the place where all appropriate documentation is assembled and stored. The most essential documentation includes the following:

1. Radioactive materials licenses, their amendments, renewals, and support materials
2. Records of communications with regulatory agencies regarding all aspects of the program (e.g., licensing, inspection)
3. Records of interactions with management, the RSC (including meeting minutes and support materials), authorized users, and other personnel, as they pertain to radiation safety
4. Records of internal audits and inspections
5. Personnel radiation monitoring records
6. Records of incidents (e.g., maladministrations) and accidents (e.g., loss of control of radioactive material) including date, location, names of involved/responsible/affected individuals, event description, results of investigation, action taken/pending, resolution, decision/action taken/pending to prevent recurrence
7. Records pertinent to control of radioactive materials, from receipt to proper disposal
8. Compliance records reflecting routine and periodic radiation safety procedures (e.g., area surveys, instrument calibration, results of testing sealed sources' integrity)
9. Radiation safety training materials and records of multilevel in-services and lectures
10. Drawings of facilities and shielding reports (when appropriate)

A number of these documents now can be generated and stored as computer files; however, certain records (e.g., original licenses and occupational dose requests) bear signatures must be stored as hard copy files.

Health Physics Laboratory

The laboratory is necessary for the radiation safety staff to implement monitoring and evaluations of work environment conditions. Some or all of the following equipment must be available (15):

1. Portable monitoring equipment such as G-M counters, ionization chambers, neutron detectors, air-sampling apparatus, and velometers
2. Sample collection and preparation equipment such as air samplers or monitoring systems, shielded containers, other specialized sampling equipment such as hot cells, and remote handling devices for radiopharmacy
3. Counting equipment such as liquid scintillation counters, gamma spectrometers and associated computerized analysis equipment and software, and radioactivity calibrators/analyzers
4. Specialized vehicles if transportation of materials of any kind, and sampling or monitoring outside environment are planned

In addition, a medical facility must have instrument calibration/repair capability. This may be achieved by contracting an outside firm or by providing an in-house service. In the latter case, a close association of the radiation safety program with the clinical engineering program is essential.

Storage and Radwaste Handling Facilities

Again, depending on the scope and size of the operation, radioactive waste storage and processing require careful consideration and space/equipment allocation. Provisions for incineration, controlled space for short-lived radioisotopes, and on-site storage of volume-reduced (compaction, solidification) long-lived isotopes must now be considered, due to escalating costs of waste disposal and uncertainties of ground burial.

Financial Resources and Logistical Means to Conduct the Program

Financial resources are necessary to the purchase of appropriate equipment, services, and supplies that are needed in order to implement the program (e.g., personnel monitoring devices, equipment repair/calibration). Additionally, there are licensing and inspection fees. The RSO must be provided with logistical means to obtain necessary funds in an expedient fashion.

Continuing education is an essential component of radiation safety programs. It involves financial expenditures, which must be included in the overall budget. The RSO must be provided financial and time resources to attend professional conferences and courses, and to purchase and/or develop educational materials. Whenever a new procedure is introduced, the RSO must develop specific radiation safety procedures and provide introductory training and retraining for involved staff.

The Future of Radiation Safety

The ever-growing field of medical uses of radioactive materials and radiation-producing equipment for both diagnostic and therapeutic purposes requires continuous updates and improvements of radiation safety programs. New uses necessitate the RSO and radiation safety staff not only to stay abreast of pertinent regulations but also to be aware of the new developments in medical applications. For the most part, this is accomplished through participation in professional societies' conferences and courses, e.g., Health Physics Society (HPS), American Association of Physicists in Medicine (AAPM), and Nuclear Medicine Society (NMS). In some cases, manufacturers or distributors of specialized equipment such as High Dose Rate Brachytherapy systems provide extensive training on-site as part of the sales or service contract. It is essential for the RSO to participate in such training and to ensure the participation of all personnel who will be involved in clinical uses of such equipment.

Many new applications of radiation and radioactive materials involve uses other than diagnosis or cancer treatment. The most recent example is intravascular brachytherapy, which involves the insertion of radioactive sources into the coronary system to prevent vessel restenosis. These new applications require the RSO to be a part of a multidisciplinary team.

Another area to which the role of the RSO is extending is community involvement. Because of the versatility of experiences, individuals who hold these positions in medical institutions are perfectly suitable to serve on regulatory advisory boards and to share their knowledge of radiation with local, national, and international organizations (e.g., local fire departments and National Radiological Emergency Preparedness), with local high schools and teacher associations, and, most importantly, with the media. As we begin the 21st century and an era of energy resources shortage, it becomes crucial for radiation professionals to work diligently in efforts to stem the tide of ignorance, unreasonable fear, and misunderstanding of radiation.

Nosocomial Infection Control

History

It is impossible to consider a history of hospital acquired (i.e., nosocomial) infections without discussing how hospitals came to be. Today's large hospital is a modern, complex institution that offers a wide variety of diagnostic and therapeutic services. To many people, hospitals are synonymous with high-quality, albeit expensive, health care. Such was not always the case. In earlier days, only the poor went to hospitals, whereas the upper classes were cared for at home. But by the end of the 18th century, hospitals were accepted as the place where all patients could receive treatment. Physicians soon became aware that certain diseases, like smallpox, could spread to hospitalized patients, and the practice of segregating certain patients was accepted in many hospitals. By 1850, the demand for hospital beds had increased dramatically in European cities.

Resources were stretched and were often insufficient to provide acceptable hygienic practices.

Ignaz P. Semmelweis, Florence Nightingale, and William Farr were early pioneers in nosocomial infection control (Wenzel, 1983). Semmelweis reviewed maternal deaths in the two divisions of Vienna Lying-in Hospital. Division I was a medical student teaching service. Division II was staffed by midwife trainees. He noted that almost 10% of women delivered by Division I physicians and students died, while only 3% of women bedded in Division II delivered by midwives died. If sick women in Division I were transferred to a general hospital and died at general hospital, their deaths were not included in the Division I Lying-in statistics. Semmelweis showed that contact spread with cadaveric or necrotic material (Division I) could account for virtually all cases of puerperal fever. Semmelweis was keenly aware that he had been responsible for many cases of puerperal fever, noting, "Because of my convictions, I must here confess that God only knows the number of patients that have gone prematurely to their graves by my fault. I have handled

cadavers extensively, more than most accoucheurs. As painful and depressing, indeed, as such an acknowledgment is, still the remedy does not lie in concealment and this misfortune should not persist forever, for the truth must be made known to all concerned" (Semmelweis, 1861).

Nightingale and Farr, against a hostile, entrenched military bureaucracy showed that safe food and water and a clean environment could result in a major decrease in death rates in a military hospitals. Analyzing mortality data from hospitals during the Crimean War showed that the higher incidence of mortality in military hospitals, as compared to civilian hospitals, resulted from contagious diseases and crowding. Their work led to improve hygienic practices and a standardized reporting system for army deaths. Health care professionals are now well aware of nosocomial infection and continue to develop methods to reduce, control, or eliminate it. (Fernandes, 2000)

Clinical Engineers and Infection Control Practices

Clinical engineers can play a principal role in infection control by involvement in water quality, waste management, sterilization, infection control standards and committee work, and health professional training in areas of sterilization and medical device maintenance. Areas of work include corrective and preventive maintenance and calibration of manometers in autoclaves, analysis of the cost of sterilization, sterilization productivity analysis, assessing the effect of medical device technology as it relates to the infection control program, construction and renovation of sterilization facilities, and the development of engineering controls to reduce nosocomial infection. The clinical engineers skills in technology management are an asset to the infection control program of the health care facility. For example, good equipment assessment and procurement processes ensure that all devices related to infection control are accompanied by the operator's manual, the service and maintenance manual, replacement parts price lists, and the drawings and schematics.

The Operator's Role in Maintenance

Users of medical devices and systems are responsible for performing day-to-day "operator's maintenance." Described in operators manuals, these tasks and necessary information include initial preparation; operational use; associated risks (including the biological ones); precautions and warnings; procedures and methods of cleaning; disinfection and sterilization; assembly and functional verification; resistance to, and compatibility with, chemical agents; heat resistance; failure modes and troubleshooting; specifications such as weight, dimensions, power supply necessities; and a list of replacement parts with prices. The technical documentation enables the user to perform superficial, but important, verification of the quality of the technology.

The Maintenance Team

Maintenance activity in health care facilities should be conducted in conformity with hospital infection control policies, procedures, and objectives. The maintenance team, composed of clinical engineers, biomedical engineering technicians, and other maintenance personnel, should strive to achieve and improve measurable quality levels. Documentation of all maintenance activity is required. The team should work in conformity with the objectives and goals of the institution and its infection control committee to ensure standardized, safe, and effective results.

Physical Area for Maintenance

The infrastructure of a hospital contains systems and equipment whose proper functioning is vital for effective infection control. These systems provide water; sewers, medical gases and vacuum; laundry; sterilization; heating; ventilation and air conditioning; and refrigeration. In maintaining and servicing these systems, it is often necessary to work at the site of system installation, rather than a remote workshop. Appropriate areas should be maintained in a centralized workshop and in satellite locations throughout the hospital. The complexity of the maintenance area should be compatible with the complexity of the technology installed and with the maintenance activities to be developed. Adequate space is required for work on large systems (such as steam sterilizers), and care must be taken to minimize the dangers such as working with high temperature and high pressure steam.

Necessary Equipment

Maintenance of sterilizers typically involves measurement of: Electrical parameters; water and air flow; static and dynamic pressures; position; force; speed and acceleration; distance; frequency; weight; and temperature. To maintain sterilizers and other equipment related to infection control, the following tools should be available:

- Pressure meters for steam; water; medical gases; compressed air and clinical vacuum; and heating ventilation and air conditioning (HVAC) systems
- Manometers to measure differential pressure across the filters of HVAC systems, water, steam and pneumatic systems, ventilators, and anesthesia equipment.
- Flow meters for water; medical gases; medical compressed air and vacuum; and hydraulic circuits
- Particulate air meter for monitoring the quality of treated air atmospheres with ventilation systems or conditioned air and other isolated areas
- Air sample collectors
- Thermometers or thermocouples for temperature measurement of air, water, and steam at specific points inside equipment or systems
- Chronometers to measure cycle times
- Vacuum cleaner
- Chemical products for cleaning, disinfecting, and sterilizing surfaces of equipment
- Electrical safety analyzer

Sterilization Concepts for Clinical Engineers

A hospital must have sterilization capability. Treating patients using sterile material reduces the risks of nosocomial infection. A clinical engineer can develop a program to reduce the risks and costs of sterilization while maximizing the performance of the sterilization equipment. Absence of sterilization capability from inappropriate planning, maintenance, or use directly effects the health of patients and the financial position of the hospital, as treatments and procedures are necessarily delayed or postponed. This section describes the most common sterilization methods: Steam, ethylene oxide, gamma radiation, hydrogen peroxide, and formaldehyde.

Steam Sterilization

There are three basic methods of moist heat sterilization: Saturated steam, steam-air mixture, and super-heated water (Linvall, 1999). All of them with the same basic necessities; i.e., to remove air from the chamber, to define temperature and time of the sterilization phase, and to set the parameters for the drying phase. The air should be removed at the beginning of the cycle to facilitate steam entering every space inside the chamber and the loads. Steam transfers its thermal energy to microorganisms, which results in their death. Temperature, time, and pressure are the critical parameters of the sterilization process, and they vary depending on the specific loads, or group of loads, to be sterilized.

Removing Air from the Internal Chamber

Air in the chamber impedes heat transfer to microorganisms. Several methods are available to remove air from the chamber. Among them, single air evacuation and pulsating-air evacuation are used to reach a specific cycle configuration. Single air evacuation is less effective and obtains residual values on the order of 1% of the initial amount of air inside the chamber. Pulsating air evacuation is applied in three steps. At the end of the first pulse, 15% of the amount of initial air remains in the chamber, and at the end of the second and third pulses, 2.25%–0.4%, respectively, of the initial air is retained.

The configuration of the sterilization cycle must account for the permeability of wrappers and other packaging material. Appropriate use of these will reduce the processing time.

Typical Cycle Curve

A typical steam sterilization cycle is shown in Figure 114-1. The data in Figure 114-1 were obtained with a data acquisition system during an inspection and document the performance of the equipment at a particular sterilization cycle configuration. An array of temperature sensors should be placed as follows:

- Establish three imaginary planes parallel to the frontal plane of the chamber.
- In the case of a square chamber, the imaginary plane
- will make intersection with the four corners inside the same, defining other 4 points.
- Place one sensor at each point of the corner, 12 (4 inches the front plane, 4 inches the plane of the middle, and 4 inches the plane of the bottom).
- One sensor is placed at the coldest point of the chamber, typically the drain.
- The last sensor is placed in the geometric center of the chamber.

The data thus obtained allow calculating the equivalent time; the F_0 -value; and the differences between the maximum and center temperatures, between lower and center temperatures, and between lower and maximum temperatures. The analysis of these data enables the assessment of the performance of the cycle.

To create specific parameters for different types of loads, it is necessary to use the concept of F_0 -value (i.e., the lethality of the cycle expressed in terms of the equivalent time), in minutes, at a temperature of 121°C with reference to microorganisms possessing a Z-value (see Glossary) of 10°C.

Sterilization Control Process

The safest and most economical (e.g., fastest) method is heat treatment; i.e. steam under pressure in a sterilizer, achieving sterilization within a minimum of 15 minutes at +121°C (250°F) or 3 minutes at 134°C (273°F). Other times and temperatures can achieve the same killing effect (e.g., 121°C for 20 minutes). The F_0 -value is expressed in equation 114-1. F is the time in minutes at a temperature, T (°C). Z is the Z-value.

$$F_0 = F \times 10^{(T - 121)/Z} \quad (114-1)$$

Example 1: How long should a product be heat-treated at 115°C to achieve $F_0 = 8$ if Z-value = 10°C?

$$8 = F \times 10^{(115 - 121)/10}$$

$$8 = F \times 10^{-0.6}$$

$$F = 32 \text{ minutes}$$

According to practice, it is assumed that a bacterial population has Z-value = 10 and D_{121} -value = 1 minute. It is also assumed that the population of microorganisms is 100 bacteria/container ($N_0 = 100$) and that this container should be sterilized at 121°C to achieve a probability of survival $N = 10^{-6}$. Equation 114-2 applies:

$$F_0 = D_{121} (\log N_0 - \log N)$$

$$F_0 = 1 (\log 100 - \log 10^{-6})$$

$$F_0 = 1 \times (2 - (-6))$$

$$F_0 = 8 \text{ minutes} \quad (114-2)$$

Example 2: How long should a product be heat-treated at 114°C to achieve $F_0 = 3.65$ if the Z-value = 15°C?

Figure 114-1 Typical steam sterilization cycle.

$$8 = F \times 10^{(114 - 121)/15}$$

$$8 = F \times 10^{-0.47}$$

$$F = 10.7 \text{ minutes}$$

According to practice, it is assumed that a bacterial population has Z-value = 15 °C and D_{121} -value = 0.5 minute. It is also assumed that there is a population of 20 bacteria/container ($N_0 = 20$) and this container shall be sterilized at 121°C to achieve a probability of survival $N = 10^{-6}$.

Using equation 114-2,

$$F_0 = D_{121} (\log N_0 - \log N)$$

$$F_0 = 0.5 (\log 20 - \log 10^{-6})$$

$$F_0 = 0.5 \times (1.3 - (-6))$$

$$F_0 = 3.65 \text{ minutes}$$

Steam Sterilization Equipment

Figure 114-2 presents all components of an autoclave and permit to understand the principle of operation. Today, all phases of the cycle are automated and computer controlled.

Ethylene Oxide

EtO is also known as “epoxitane” or “dimethylene oxide.” It is a colorless gas and reacts with several chemicals, such as alcohols, amines, organic acids and amides. It is soluble in water to 10°C, and it forms polyglycols in the presence of bases. It is highly inflammable and explosive. While it is occasionally used in the pure form, EtO is usually used in diluted mixtures. Because ethylene oxide (EtO) can sterilize at low temperatures, the main advantage of this gas for hospital sterilization is that it will not damage heat sensitive materials, such as plastics.

Gas concentration, sterilization temperature, chamber humidity, and exposure time affect EtO sterilization. Adjusting these parameters according to the load can optimize the sterilization process. Basically, there are two types of sterilization cycles. The first uses positive pressure inside the chamber because EtO is diluted with other gases in order to diminish its explosivity. The second uses negative pressure inside the chamber, because they use EtO 100% pure. In this case, if there is a hole in the chamber, the gas will not escape easily.

The main disadvantage of EtO is its toxicity to patients and personnel if it is not properly utilized. EtO brings serious risks of chemical burns to body tissues if a device, such as a plastic or rubber face mask, sterilized in EtO is not aerated (aeration cycle) after the sterilization cycle to allow the EtO absorbed during the cycle to elute from the mask, is placed in contact with the patient (Dyro and Tai, 1976). The use of EtO in hos-

pitals is decreasing because of such factors as risks to health, environmental concerns over waste sterilant disposal, and longer turnaround time. Hospitals that utilize contract sterilizer companies must be concerned with the quality of that company’s sterilization process.

Gamma Radiation

Gamma radiation is pure energy generated by the spontaneous decay of radioisotopes. Exposure to gamma rays sterilizes the product by disrupting the DNA structure of microorganisms on or within the product, thereby eliminating the ability to reproduce life sustaining cells. The ionizing energy produced by gamma rays is deep penetrating, thus making it an ideal solution for products with various densities and product packaging types. No area of the product, its components, or packaging is left with uncertain sterility after treatment. Even high-density products, such as pre-filled syringes, can be readily processed and used with confidence. The gamma process is repeatable and easy to use, with a proven track record. Its deep penetrating capabilities make it a viable solution for a wide range of packaged products. Accompanying dosimetric-release procedures allow for the immediate shipment of products after sterilization processing.

Gamma radiation has been recognized as a safe, cost-competitive method for the sterilization of health care products, components, and packaging since the 1950s and has gained in popularity over the years, due to its simplicity and reliability. Gamma radiation effectively kills microorganisms throughout the product and its packaging, with little temperature effect. Benefits of gamma radiation are precision dosing, rapid processing, uniform-dose distribution, system flexibility, and the immediate availability of the product after processing.

Gamma radiation of single-use, disposable medical devices for the purpose of sterilization is being used by an ever-increasing percentage of the health care industry. Gamma radiation, which once accounted for only 5% of the sterilization market, has grown to nearly 50%. Although cost and reliability have been identified as contributing factors to the industry’s conversion to gamma radiation, there are other key elements to be considered.

Packaging remains intact with gamma processing. As there is no requirement for pressure or vacuum, seals are not stressed. In addition, gamma radiation eliminates the need for permeable packaging materials. Packaging and raw materials suppliers have recognized the shift to radiation and are continuing to develop products that are specifically formulated for radiation stability. Tough, impermeable packaging materials are available to provide a strong, long-term, sterile barrier.

Gamma processing, is a highly reliable procedure, mostly due to its simplicity. Because time is the only variable to control, the possibility of deviation is reduced to a minimum. Gamma radiation allows for the immediate release of the product after processing, through a procedure known as “dosimetric release.” This procedure is accepted by the

Figure 114-2 Schematic diagram of a typical steam sterilizer.

U.S. Food and Drug Administration (FDA) due to the inherent reliability of the radiation process and is outlined, in detail, in the standards document *ANSI/AAMI/ISO 11137-1994, Sterilization of Health Care Products—Requirements for Validation and Routine Control—Radiation Sterilization*.

Dosimetric release is a product release mechanism, based solely on the dosage of radiation delivered to the product. This measurement, usually identified in kiloGrays (kGy), is obtained using dosimeters, which are placed on product containers during processing. Upon completion of the gamma process, the dosimeters are removed from the product containers and are read, using a specialized instrument to verify the minimum and maximum dosages received by the product. Once the delivered dose is verified, the product is released for shipment.

Hydrogen Peroxide

A hydrogen peroxide gas cloud or low temperature plasma produced by a strong electrical field is suitable for sterilization of surfaces. Low temperature hydrogen peroxide gas plasma sterilization has been available in the United States since 1993. Hydrogen peroxide plasma is formed directly in the sterilization chamber, rather than in a separate reaction chamber (Figure 114-3). During low temperature hydrogen peroxide gas plasma sterilization, medical devices and surgical instruments are placed in the sterilization chamber, and a vacuum is applied to remove the air. A solution of 58% hydrogen peroxide in water is injected into an outer chamber from a self-contained cassette inserted by the operator at the beginning of every 10 sterilization cycles. The solution is then vaporized and allowed to diffuse throughout the sterilization chamber, surrounding the items to be sterilized. Radio frequency (RF) energy is then applied to create an electromagnetic field, which in turn initiates the generation of the plasma. At the conclusion of the sterilization cycle after approximately one hour, the electromagnetic field is turned off, and the reactive hydrogen peroxide species rapidly revert primarily to water vapor and oxygen. The sterilization chamber is repressurized, and the air is passed through an activated charcoal filter to remove any residual hydrogen peroxide.

Advantages of low temperature hydrogen peroxide gas plasma system include an excellent safety profile for employees. Unlike EtO, liquid chemical sterilants, and other alternative sterilization technologies, low temperature hydrogen peroxide gas plasma sterilizer poses little risk to operators and the environment. Exposure to hydrogen peroxide has been limited to 1 ppm over eight hours by Occupational Safety and Health Agency (OSHA) regulations. Monitoring by OSHA of the external environment of the sterilizer during operation has demonstrated that the average concentration of hydrogen peroxide in the atmosphere over eight hours is 0.018 ppm, while the personal sample exposure is 0.013 ppm.

Safety for patients has been established through laboratory tests of the low temperature hydrogen peroxide gas plasma technology prior to market clearance in 1993. These tests have demonstrated that this technology destroys a broad spectrum of micro organisms, including Gram-negative and Gram-positive vegetative bacteria, mycobacterium, yeast, fungi, and viruses, as well as highly resistant aerobic and anaerobic bacterial spores. In addition, as the hydrogen peroxide breaks down into water and oxygen, there are no concerns about toxic residues following the completion of a sterilization cycle.

Studies have demonstrated that items processed by this technology are nonirritating and nontoxic to cells and tissues.

Significant economic advantages have been associated with low temperature gas plasma sterilization as well. For example, because of its extremely rapid cycle time (about one hour), inventory of expensive surgical instruments such as rigid endoscopes can be reduced while still ensuring that every patient receives a sterilized, not just disinfected, device at any given time of the day. In addition, for a wide range of medical and surgical instruments processed by low temperature hydrogen peroxide gas plasma sterilization, significantly less deleterious effects on metal items have been observed, as compared with steam sterilization, reducing replacement costs of expensive surgical instruments. Because there are no installation requirements except a modified 208-volt electrical outlet, the system can be placed almost anywhere, including the surgical suite, to facilitate the distribution of sterile instruments. Finally, because preparation of items for sterilization is similar to EtO processing, consisting of instrument cleaning, reassembly, and packaging in commercially available, nonwoven polypropylene wraps, employee training costs can be kept to a minimum.

Environmental concerns are addressed in the fundamental manner in which the technology operates: Self-contained ampoules of hydrogen peroxide are used that virtually eliminate concerns about exposure to the chemical. In addition, following the completion of the sterilization cycle, the hydrogen peroxide degrades primarily into vaporized water and oxygen, free of toxic materials associated with other low temperature technologies.

Disadvantages of this technology include the inability to sterilize linens and other cellulose containing materials, as the hydrogen peroxide reacts with the organic material found in these items. In addition, because the technology relies upon diffusion, materials such as powders and liquids cannot be sterilized. Special attention should be given when considering applications for narrow lumen devices.

As the shift occurs away from traditional low temperature sterilization technologies (such as EtO and liquid chemical germicides) to the newer methods, the full spectrum of medical sterilization technology comes into focus. While no single technology can fulfill all of the sterilization needs of a hospital, a range of safe, economical choices is imperative. Dry heat and steam probably will always have an appropriate place in the provision of this service. Low temperature systems that are potentially dangerous and costly might not.

Hydrogen peroxide is not recommended for the following materials because they can become brittle, and they have absorption problems (the sterilization is effective, but the material degrades with the time):

- Biphenol and epoxy or components done of polysulfone or polyurethane
- Nylon and cellulose
- Polymethylmethacrylate, polycarbonate, and vinylacetate
- Cellulose

It can be used for temperature sensitive materials and other materials such as the following:

- Catheters with an internal diameter minimum of 1 mm and up to 2 meters in length
- Metallic instruments

- Electric equipment
- Rigid endoscopes
- Pneumatic equipment
- Endoscopic equipment
- Organic matter

Formaldehyde

Formaldehyde is a colorless gas, but it is normally distributed as a solution (generally referred to as "formalin"), and it is known to most people within hospitals as an important disinfectant that has been in use since the late 1800s (Weber-Tschopp et al., 1977).

Typical equipment suitable for processing with low temperature steam formaldehyde sterilizers include the following:

- Most types of endoscopes—both rigid (straight) and flexible (e.g., arthroscopes, cystoscopes, laparoscopes, bronchoscopes, coloscopes, gastroscopes, duodenoscopes, choledochoscopes, laryngoscopes, and nephroscopes)
- All heat sensitive instruments for advanced eye surgery
- Most plastic materials (e.g., syringes, coils, tubing, and diathermy cables)

There are, however, some products made of, or including, parts with materials that cannot stand the heat of such sterilization processes, normally at +121°C or +134°C.

Whatever the process, it must result in an approved sterile product, free from hazardous levels of residuals. It must be reasonably easy to use; must be capable of physical monitoring; must have a short process time; must be possible for the normal packaging staff to operate and control; and must be inexpensive. Moreover, the process should allow the product to be packaged in normal wrapping material so as not to create additional costs. It must result in a product that is available for immediate use, must be safe to use with standard preprocessing, and must have good safety margins. Low temperature steam formaldehyde sterilization fulfills all these requirements.

Formaldehyde solutions are widely used in autopsy, surgical, and pathology departments and, to a lesser extent, in dermatology and surgical clinics, X-ray departments and other health care units. The principal use in hospitals is for fixation of tissues.

Formaldehyde solutions are known to be toxic, irritating, and allergenic (WHO, 1986; NRC, 1980). The solution is irritating to the skin and can cause allergic reaction on long or frequent contact exposure. However, even exposure to low, harmless doses causes irritation in the eyes, nose, and throat (Gamble, 1983). This irritation compels the person exposed to avoid further contact; i.e. formaldehyde has a built-in warning signal. Consequently, allergic reactions due to presence of formaldehyde in the air are unusual.

Research on possible carcinogenic effects, based on animal studies conducted by IARC in the United States, showed little to indicate such effects of formaldehyde. The tests were conducted by exposing mice and rats to extremely high concentrations of formaldehyde for two years. In mice, no changes were found, even from exposure to a concentration level of 2-ppm. (The level of painful nasal irritation in human being starts at 0.01 ppm.) (Gamble, 1983.) When subjecting mice to extremely high concentrations (5.6–14.3 ppm), it was possible to induce chronic changes in nasal tissues. This included two cases of nasal cancer. Because the same incidence of nasal cancer is found in unexposed mice, it was concluded that the study gave no clear evidence of any carcinogenic effects of formaldehyde (CIIT, 1981).

Extensive epidemiological studies on industrial workers, pathologists, and embalmers who are regularly exposed to concentrations higher than 10 ppm have shown no long-term adverse effects. Because the extremely irritating smell of formaldehyde at very low levels tends to prevent exposure to higher concentrations, long-term exposure to carcinogenic levels is extremely rare.

Sterilization by Low Temperature Steam and Formaldehyde (LTSF)

In the LTSF process, the pure heat energy of steam sterilization is replaced by a mixture of steam and formaldehyde gas at temperatures of 80°, 65°, 60°, 55°, or 50°C (176°, 149°, 140°, 131°, or 122°F). The presence of steam allows the formaldehyde to penetrate and kill any microorganisms. This sterilization process is intended for heat sensitive goods, especially plastic and hollow instruments (e.g., rigid and flexible endoscopes), which the high temperature of a conventional steam sterilizer could damage.

The Process of Sterilization by LTSF

The LTSF process occurs in four stages:

1. Pretreatment

Before the formaldehyde is admitted, the goods are subjected to pretreatment consisting of repeated evacuations and steam flushes. Pretreatment removes air from the goods and the chamber, while simultaneously humidifying the microorganisms to make them susceptible to formaldehyde. The effectiveness of the humidifying part of the pretreatment is essential to the rest of the process.

2. Formaldehyde Admission

A formalin solution is injected from a sealed bottle. The formalin is then evaporated and enters the chamber as a gas. A vacuum in the chamber assists the admission of the gas. Steam is then added to keep the temperature at the predetermined level. The admission is repeated several times to enhance the penetration into long, narrow lumens and cavities.

3. Sterilization

During the exposure time, the chamber is maintained at the specified temperature, sterilant concentration, pressure, and humidity.

4. Post-Treatment

After the pre-determined sterilizing exposure time, the formaldehyde is effectively removed from the goods by repeated vacuum and intermediate steam flushes. The post-treatment process ends with a deep vacuum, followed by a significant number of pulsating air flushes via the air admission filter. This part of the process removes residual formaldehyde in the goods and the chamber (Handlos, 1977).

The formaldehyde concentration in the air by the sterilizer door is generally a maximum of 0.5 ppm and drops to zero ppm within a few minutes. Formaldehyde in the sterilizer drain is diluted to 0.01% and is then decomposed quickly by microorganisms in the sewage.

Indicators

Medical authorities worldwide have recognized that it is not enough to check the sterilization process by physical means (e.g., charts and gauges). Additional controls—primarily chemical and biological—are also required. Various biological and chemical control methods, with varying degrees of accuracy and reliability, are available today. In order to have a parameter to control the quality of process in a daily frequency, operators must use complementary tests. They use indicators to evaluate the results of the sterilization process.

Figure 114-3 A typical cycle of the hydrogen peroxide sterilization process.

Chemical Indicators

This control method gives a clear, instant pass-or-fail indication by a change of color. Indicators are available as spots or strips. Spots are normally used as indicators on the outside of a pack, while the strip indicator should be placed inside the pack or inside a challenge device. It is used to show, via color change, that formaldehyde gas has penetrated and has been present in sufficient quantity, and for a sufficient period of time, to achieve sterilization.

Biological Indicators

As mentioned above, vital factors for good sterilization results are the removal of air and the access of humidity and sterilizing agent. This can be difficult to achieve if a sterilizer with a poorly designed vacuum system is used. Biological indicators, prepared from *Bacillus stearothermophilus* and resistance tested against formaldehyde, are placed inside a pack and provide reliable controls for steam sterilization.

The following two types of biological indicators are available:

1. Challenge devices (for laboratory cultivation): Because the low temperature steam formaldehyde sterilization process is mainly used for narrow and optical instruments, a special challenge test method has been developed to simulate a complex instrument. The challenge test unit consists of a narrow (2 mm inside diameter), one-way lumen, 1.5 m long, with an indicator at the closed end of the tube.
2. Self-contained biological indicators (for local testing): They include both the test organism and the cultivation broth.

Residual Tests

This challenge method of testing for formaldehyde residuals is based on filter paper. Evaluation is performed in a chemical laboratory, according to standard practice. In this test, residuals represent a worst case (absorbing materials) and are not representative of residuals on nonabsorbent instruments.

Waste Management

Hospital waste is considered to be hazardous residue. Its risk comes from the possibility of disease transmission such as AIDS, hepatitis B and C, and numerous bacteria resistant infections. Health workers and their families are most at risk. Next at risk are patients, visitors, municipal employees, recycling personnel, and neighboring inhabitants.

Not all trash dumped by health centers is dangerous. It is calculated that 80% could be considered as general or common, as it is composed of the same material and has the same quantity and type of bacteria as domestic trash generated city homes. Only 20% have health risks because of bacteria, viruses, fungi, parasites, toxic chemical products, medicine remains, radioactive material, and sharp objects (e.g., sharps). Sharps are the highest risk because viruses and bacteria can be easily transmitted through cuts and perforations. (See Chapter 61 for a discussion of the disposal of sharps.)

Management of Health Care Waste

The first aspect to consider in a program of residue administration in a hospital refers to legal demands of a country, state, or municipal district. Information from other qualified organizations can contribute to the effective implantation of this program (LWRA, 1994; WHO, 1997). In a general these organizations establish obligations that should be considered in the project, implantation, and maintenance of program. It is important to consider that legal aspects can be used to educate, and therefore that they should be used as learning instruments. A concentrated effort in assisting the orientations of these organizations allows the planner to obtain information and to conduct a series of considerations on the following:

- Processes or technologies that are in use, in disuse, and prohibited
- The details of a specific program as geographical aspects
- Recommendations from technical norms that must be considered in the elaboration of the a program
- The specification of advisable and obligatory technologies
- Classifications of residues
- Applicable definitions to this type activity
- The procedures to be adopted during hospital internal processing
- The collection procedure intern and it expresses to the hospital
- Obtaining licenses, technological viability, adaptation of equipments, fiscalization, treatment, and final destination of the residues
- Applicable symbology
- Other attributions and responsibilities of others related organs

The basis of management is to avoid the mixture of various types of waste because infectious material easily spreads into organic trash and multiplies within it at great speed, which makes it impossible to separate at the end. Handling stages comprise separation from its original place, gathering, separate transportation, dangerous material treatment, and final secure dump. If the technical norms of separation have not been executed, all trash generated at the hospital could be infectious, and the production of dangerous wastes, therefore, is five times greater than expected.

Categories of Health Care Waste

Infectious waste: Waste that is suspected to contain pathogens; e.g., laboratory cultures; waste from isolation wards; or tissues (swabs), materials, or equipment that has been in contact with infected patients

Pathological waste: Human tissues or fluids; e.g., body parts; blood and other bodily fluids; Sharps waste; e.g., needles; infusion sets; scalpels; knives; blades; and broken glass

Pharmaceutical waste: Waste containing pharmaceuticals; e.g., pharmaceuticals that are expired or no longer needed; items contaminated by, or containing, pharmaceuticals

Genotoxic waste: Waste that contains substances with genotoxic properties; e.g., waste containing cytostatic drugs (often used in cancer therapy)

Chemical waste: Waste containing chemical substances e.g., laboratory reagents; film developer; disinfectants that are expired or no longer needed; or solvents

Wastes with high content of heavy metals: Batteries, broken thermometers, and blood-pressure gauges.

Pressurized containers: Gas cylinders; gas cartridges; and aerosol cans

Radioactive waste: Waste containing radioactive substances e.g., unused liquids from radiotherapy or laboratory research; contaminated glassware, packages, or absorbent paper; urine and excreta from patients treated or tested with unsealed radionuclides; and sealed sources

Major sources of health care waste:

- Hospitals: (university hospitals, general hospitals, district hospitals, and other health care establishments)
- Emergency medical care services
- Health care centers and dispensaries
- Obstetric and maternity clinics
- Outpatient clinics
- Dialysis centers
- First-aid posts and sick bays
- Long-term health care establishments and hospices
- Transfusion centers
- Military medical services
- Medical and biomedical laboratories
- Biotechnology laboratories and institutions
- Medical research centers
- Mortuary and autopsy centers
- Animal research and testing
- Blood banks and blood collection services
- Nursing homes for the elderly

Laboratories: Mainly pathological (including some anatomical) produce highly infectious waste (small pieces of tissue, microbiological cultures, stocks of infectious agents, infected animal carcasses and blood), sharps and some radioactive and chemical waste.

Health care waste generation depends on numerous factors, such as established waste-management methods, type of health care establishment, hospital specialty, the proportion of reusable items employed in health care, and proportion of patients treated on a day-care basis. In middle- and low-income countries, health care waste generation is usually lower than in high-income countries. The amount of radioactive health care waste is generally extremely small, as compared with the radioactive waste produced by the nuclear industry.

Waste Segregation and Packaging

The keys to minimization and effective management of health care waste are segregation (separation) and identification of the waste. Appropriate handling, treatment, and disposal of waste by type reduce costs and do much to protect public health. Segregation always should be the responsibility of the waste producer, should take place as close as possible to where the waste is generated, and should be maintained in storage areas and during transport. The same system of segregation should be in force throughout the country.

The most appropriate way of identifying the categories of health care waste is by sorting the waste into color-coded plastic bags or containers. The recommended color-coding scheme is given in Table 114-1. In addition to the color coding of waste containers, the following practices are recommended:

- General health care waste should join the stream of domestic refuse for disposal.
- Sharps should be collected together, regardless of whether or not they are contaminated. Containers should be puncture-proof (usually made of metal or high-density plastic) and fitted with covers. They should be rigid and impermeable so that they safely retain not only the sharps but also any residual liquids from syringes. To discourage abuse, containers should be tamper-proof, and needles and syringes should be rendered unusable. Where plastic or metal containers are unavailable or too costly, containers made of dense cardboard are recommended.

Table 114-1 Recommended color-coding for health care waste

<i>Recommended color-coding for health care waste</i>		
Type of waste	Color of container and markings	Type of container
Highly infectious waste	Yellow, marked "highly infectious"	Strong, leak-proof plastic bag, or container capable of being autoclaved
Other infectious waste, pathological and anatomical waste	Yellow	Leak-proof plastic bag or container
Sharps	Yellow, marked "sharps"	Puncture-proof container
Chemical and pharmaceutical waste	Brown	Plastic bag or container
Radioactive waste	-	Lead box, labelled with the radioactive symbol
General health care waste	Black	Plastic bag

- Bags and containers for infectious waste should be marked with the international infectious substance symbol, as described in Figure 114-4.
- Whenever possible, highly infectious waste should be sterilized immediately by autoclaving. It therefore must be packaged in bags that are compatible with the proposed treatment process: Red bags, suitable for autoclaving, are recommended.
- Cytotoxic waste, most of which is produced in major hospital or research facilities, should be collected in strong, leak-proof containers clearly labeled "Cytotoxic wastes."
- Small amounts of chemical or pharmaceutical waste can be collected together with infectious waste.
- Large quantities of obsolete or expired pharmaceuticals stored in hospital wards or departments should be returned to the pharmacy for disposal. Other pharmaceutical waste generated at this level, such as spilled or contaminated drugs or packaging containing drug residues, should not be returned because of the risk of contaminating the pharmacy; it should be deposited in the correct container at the point of production.
- Large quantities of chemical waste should be packed in chemical-resistant containers and sent to specialized treatment facilities (if available). The identity of the chemicals should be clearly marked on the containers: Hazardous chemical wastes of different types should never be mixed.
- Waste with a high content of heavy metals (e.g., cadmium or mercury) should be collected separately.
- Aerosol containers may be collected with general health care waste once they are completely empty, if the waste is not destined for incineration.
- Low-level radioactive infectious waste (e.g., swabs, syringes for diagnostic or therapeutic use) may be collected in yellow bags or containers for infectious waste if these are destined for incineration.

Because costs for safe treatment and disposal of hazardous health care waste typically are more than 10 times higher than those for general waste, all general (i.e., non-hazardous) waste should be handled in the same manner as domestic refuse and collected in black bags. No health care waste other than sharps should be deposited in sharp containers, as these containers are more expensive than the bags used for other infectious waste. Measures of this sort help to minimize the costs of health care waste collection and treatment. When a disposable syringe is used, for example, the packaging should be placed in the general waste bin, and the used syringe in the yellow sharps container. Under most circumstances, the needle should not be removed from the syringe because of the risk of injury. If removal of the needle is required, special care must be taken.

Appropriate containers or bag holders should be placed in all locations where particular categories of waste can be generated. Instructions on waste separation and identification should be posted at each waste collection point to remind staff of the procedures. Containers should be removed when they are three-quarters full. Ideally, they should be made of combustible, nonhalogenated plastics.

Staff should never attempt to correct errors of segregation by removing items from a bag or container after disposal or by placing one bag inside another bag of a different color. If general and hazardous wastes are accidentally mixed, the mixture should be treated as hazardous health care waste.

Cultural and religious constraints in certain countries make it unacceptable for anatomical waste to be collected in the usual yellow bags; such waste should be disposed of in accordance with local custom, which commonly specifies burial (MoH, 1995).

On-Site Collection

Nursing and other clinical staff should ensure that waste bags are tightly closed or sealed when they are about three-quarters full. Tying the neck can close light-gauge bags, but heavier-gauge bags probably require a plastic sealing tag of the self-locking type. Bags should not be stapled. Sealed sharps containers should be placed in a labeled, yellow, infectious health care waste bag before removal from the hospital ward or department. Wastes should not be allowed to accumulate at the point of production. A routine program for their collection should be established as part of the health care waste management plan.

- Waste should be collected daily (or as frequently as required) and transported to the designated central storage site.
- No bags should be removed unless they are labeled with their point of production (i.e., hospital and ward or department) and contents.
- The bags or containers should be replaced immediately with new ones of the same type.
- A supply of fresh collection bags or containers should be readily available at all locations where waste is produced.

On-Site Storage

A storage location for health care waste should be designated inside the health care establishment or research facility. The waste, in bags or containers, should be stored in a separate area, room, or building of a size appropriate to the quantities of waste produced and the frequency of collection. Recommendations for the storage area and its equipment are listed below.

- The storage area should have an impermeable, hard-standing floor with good drainage; it should be easy to clean and disinfect.
- There should be a water supply for cleaning purposes.
- The storage area should afford easy access for staff in charge of handling the waste.
- It should be possible to lock the store to prevent access by unauthorized persons.
- Easy access for waste-collection vehicles is essential.
- There should be protection from the sun.
- The storage area should be inaccessible for animals, insects, and birds.
- There should be good lighting and at least passive ventilation.
- The storage area should not be situated in the proximity of fresh food stores or food preparation areas.
- A supply of cleaning equipment, protective clothing, and waste bags or containers should be located conveniently close to the storage area.

- Unless a refrigerated storage room is available, storage times for health care waste (i.e., the delay between production and treatment) should not exceed the following:

Temperate climate: 72 hours in winter and 48 hours in summer

Warm climate: 48 hours during the cool season, and 24 hours during the hot season

- Cytotoxic waste should be stored separately from other health care waste in a designated secure location.
- Radioactive waste should be stored in containers that prevent dispersion, and behind lead shielding. Waste that is to be stored during radioactive decay should be labeled with the type of radionuclide, the date, and details of required storage conditions.

Transportation

Health care waste should be transported within the hospital or other facility by means of wheeled trolleys, containers, or carts that are not used for any other purpose and that meet the following specifications:

- Ease of loading and unloading
- No sharp edges that could damage waste bags or containers during loading and unloading
- Ease of cleaning

The vehicles should be cleaned and disinfected daily with an appropriate disinfectant. All waste bag seals should be in place and intact at the end of transportation.

The health care waste producer is responsible for safe packaging and adequate labeling of waste to be transported offsite and for authorization of its destination. Packaging and labeling should comply with national regulations governing the transport of hazardous wastes and with international agreements if wastes are shipped abroad for treatment.

The control strategy for health care waste should have the following components:

- A consignment note should accompany the waste from its place of production to the site of final disposal. On completion of the journey, the transporter should complete the part of the consignment note (especially reserved for him) and return it to the waste producer.
- The transporting organization should be registered with, or known to, the waste regulation authority.
- Handling and disposal facilities should hold a permit, issued by a waste regulation authority, allowing the facilities to handle and dispose of health care waste.

The consignment note should be designed to take into account the waste control system in operation within the country. The "Multimodal Dangerous Goods Form" recommended by the United Nations can be taken as an example.

If a waste regulation authority is sufficiently established, it might be possible to prenotify the agency about the planned system of transport and disposal of the health care waste and to obtain the agency's approval.

Anyone involved in the production, handling, or disposal of health care waste has a general "duty of care," (i.e. an obligation to ensure that waste handling and associated documentation comply with the national regulations).

Transportation Vehicles and Containers

Waste bags may be placed directly into the transportation vehicle, but it is safer to place them in further containers (e.g., cardboard boxes or wheeled, rigid, lidded plastic, or galvanized bins). This has the advantage of reducing the handling of filled waste bags but results in higher disposal costs. These secondary containers should be placed close to the waste source.

Any vehicle used to transport health care waste should fulfill the following design criteria:

- The body of the vehicle should be of a suitable size, commensurate with the design of the vehicle, with an internal body height of 2.2 meters.
- There should be a bulkhead between the driver's cabin and the vehicle body that is designed to retain the load if the vehicle is involved in a collision.
- There should be a suitable system for securing the load during transport.
- Empty plastic bags, suitable protective clothing, cleaning equipment, tools, and disinfectant, together with special kits for addressing liquid spills, should be carried in a separate compartment in the vehicle.
- The internal finish of the vehicle should allow it to be steam-cleaned, and the internal angles should be rounded.
- The vehicle should be marked with the name and address of the waste carrier.
- The international hazard sign should be displayed on the vehicle or container, as well as an emergency telephone number.

Vehicles or containers used for the transportation of health care waste should not be used for the transportation of any other material. They should be kept locked at all times, except when loading and unloading.

Articulated or demountable trailers (temperature-controlled if required) are particularly suitable as they can be easily left at the site of waste production. Other systems may be used, such as specially designed large containers or skips; however, open-topped skips or containers never should be used for transporting health care waste.

Where the use of a dedicated vehicle cannot be justified, a bulk container that can be lifted on to a vehicle chassis may be considered. The container may be used for storage at the health care establishment and replaced with an empty one when collected. Refrigerated containers may be used if the storage time exceeds the above recommendations for on-site storage or if transportation times are long. The finish of these bulk containers should be smooth and impervious and should permit easy cleansing or disinfection.

The same safety measures should apply to the collection of hazardous health care waste from scattered small sources. Health care establishments that practice minimal programs

of health care waste management should either avoid off site transportation of hazardous waste or at least use closed vehicles to avoid spillage. The internal surfaces of any vehicle used for this purpose should be easy to clean.

Health care waste should be transported by the quickest possible route, which should be planned before the journey begins. After departure from the waste production point, every effort should be made to avoid further handling. If handling cannot be avoided, it should be pre-arranged and should take place in adequately designed and authorized premises. Handling requirements can be specified in the contract established between the waste producer and the carrier.

Special Packaging for Offsite Transport

In general, the waste should be packaged according to the recommendations provided above (see Table 114-1) in sealed bags or containers, to prevent spilling during handling and transportation. The bags or containers should be appropriately robust for their content (e.g., puncture-proof for sharps, for example, or resistant to aggressive chemicals) and for normal conditions of handling and transportation, such as vibration or changes in temperature, humidity, or atmospheric pressure.

In addition, radioactive material should be packed in containers whose surfaces can be easily decontaminated. The United Nations recommends further packing requirements for infectious substances (UN, 1997). For infectious health care wastes, it is recommended that packaging should be design-type tested and certified as approved for use. Health care wastes that are known or suspected to contain pathogens that are likely to cause human disease should be considered “infectious substances” and should comply with the packaging requirements indicated in Table 114-2.

The packaging should include the following essential elements:

- An inner packaging comprising:
 - Watertight primary receptacle of metal or plastics with leak-proof seal (e.g., a heat seal, a skirted stopper, or a metal crimp seal);
 - A watertight secondary packaging;
 - Absorbent material in sufficient quantity to absorb the entire contents placed between the primary receptacle and the secondary packaging.
- An outer packaging of adequate strength for its capacity, mass, and intended use, and with a minimum external dimension of 100mm.
- A list of contents should be enclosed between the secondary packaging and the outer packaging. The outer packaging should be appropriately labeled.

The packaging recommended for most health care wastes, with a relatively low probability that infectious substances are present and which are not likely to cause human disease.

There are two possibilities for packaging:

- Rigid and leak-proof packaging.
- Intermediate bulk containers—large, rigid or flexible, bulk containers made from a variety of materials such as wood, plastic, or textile.

Packaging or intermediate bulk containers that are intended to contain sharp objects such as broken glass and needles shall be resistant to puncture and shall undergo additional performance tests.

Labeling

All waste bags or containers should be labeled with basic information on their content and on the waste producer. This information may be written directly on the bag or container or on preprinted labels, securely attached.

For health care waste, the following additional information should be marked on the label:

- Waste category
- Date of collection
- Place in hospital where produced (e.g., ward)
- Waste destination

In case of problems involving questions of liability, full and correct labeling allows the origin of the waste to be traced. Labeling also warns operative staff and the public of the hazardous nature of the waste. The hazards posed by container contents can be quickly identified in case of accident, enabling emergency services to take appropriate action.

Cytotoxic waste should be marked with the label “Cytotoxic waste.”

Three labels have been designed by the UN/IAEA for radioactive material, providing information on the levels of activity of a given package (IAEA, 1996).

Unless the package is large (and it is assumed here that all packages containing radioactive waste do not exceed 1m² in cross-sectional area), radiation symbol the labels should be chosen according to Table 114-2. If the two types of conditions in Table 114-2 differ, the package should be assigned to the higher category.

Treatment and Disposal Technologies for Health Care Waste

Incineration was formerly the method of choice for most hazardous health care waste and is still widely used. However, recently developed alternative treatment methods are becoming increasingly popular. The final choice of treatment system should be made carefully on the basis of various factors, many of which depend on local conditions, listed below:

- Disinfection efficiency
- Health and environmental considerations
- Volume and mass reduction
- Occupational health and safety considerations
- Quantity of wastes for treatment and disposal/capacity of the system
- Types of waste for treatment and disposal
- Infrastructure requirements
- Locally available treatment options and technologies
- Options available for final disposal
- Training requirements for operation of the method
- Operation and maintenance considerations
- Available space
- Location and surroundings of the treatment site and disposal facility
- Investment and operating costs
- Public acceptability
- Regulatory requirements

Certain treatment options may effectively reduce the infectious hazards of health care waste but, simultaneously, give rise to other health and environmental hazards. Land disposal may result in groundwater pollution if the landfill site is inadequately designed. In choosing a treatment or disposal method for health care waste, particularly if there is a risk of toxic emissions or other hazardous consequences, the relative risks, as well as the integration into the overall framework of comprehensive waste strategy, therefore should be carefully evaluated in the light of local circumstances.

Incineration

Incineration is a high temperature, dry oxidation process that reduces organic and combustible waste to inorganic, incombustible matter and results in a significant reduction of waste volume and weight. This process is usually selected to treat wastes that cannot be recycled, reused, or disposed of in a landfill site.

The combustion of organic compounds produces mainly gaseous emissions, including steam, carbon dioxide, nitrogen oxides, and certain toxic substances (e.g., metals, halogen acids), and particulate matter, plus solid residues in the form of ashes. If the conditions of combustion are not properly controlled, toxic carbon monoxide also will be produced. The ash and wastewater produced by the process also contain toxic compounds, which have to be treated to avoid adverse effects on health and the environment.

Most large, modern incinerators include energy recovery facilities. In cold climates, steam or hot water from incinerators can be used to feed urban district heating systems, and in warmer climates the steam from incinerators is used to generate electricity. The heat recovered from small hospital incinerators is used for preheating of waste to be burnt.

Characteristics of Waste Suitable for Incineration

- Content of combustible matter above 60%
- Content of noncombustible solids below 5%
- Content of noncombustible fines below 20%
- Moisture content below 30%

Waste types not to be incinerated

- Pressurized gas containers
- Large amounts of reactive chemical waste
- Silver salts and photographic or radiographic wastes
- Halogenated plastics such as polyvinyl chloride (PVC)
- Waste with high mercury or cadmium content, such as broken thermometers, used batteries, and lead-lined wooden panels
- Sealed ampoules or ampoules containing heavy metals

Types of Incinerators

Incinerators can range from extremely sophisticated, high temperature operating plants to basic combustion units that operate at much lower temperatures. All types of incinerators, if operated properly, eliminate pathogens from waste and reduce the waste to ashes. However, certain types of health care waste, e.g., pharmaceutical or chemical waste, require higher temperatures for complete destruction. Higher operating temperatures and

Table 114-2 Categories of packages for radioactive waste (IAEA, 1996)

<i>Categories of packages for radioactive waste</i>		
<i>Conditions</i>	<i>Conditions</i>	<i>Category</i>
Maximum radiation level at a distance of 1 m from the external surface of the package Not more than 0,0005 mSv/h	Maximum radiation level at any point on the external surface Not more than 0,005 mSv/h	I-WHITE
More than 0,0005 mSv/h but not more than 0.01 mSv/h	More than 0,005 mSv/h but not more than 0.5 mSv/h	II-YELLOW
More than 0,01 mSv/h but not more than 0.1 mSv/h	More than 0,5 mSv/h but not more than 2 mSv/h	III-YELLOW

cleaning of exhaust gases limit the atmospheric pollution and odors produced by the incineration process.

Incinerators are designed especially for treatment of health care waste and operated at temperatures between 900°C and 1200°C. Low cost, high temperature incinerators of simple design are currently being developed, and a system designed specifically for health care and pharmaceutical waste in low-income countries is currently under test. Mobile incinerators for health care waste have been tested; those units permit on-site treatment in hospitals and clinics, thus avoiding the need to transport infectious waste through city streets. Test results for units with a capacity of 30 kg/hour were satisfactory in terms of function, performance, and air pollution.

High temperature incineration of chemical and pharmaceutical waste in industrial cement or steel kilns is practiced in many countries and is a valuable option; no additional investments are required, and industry benefits from a supply of free combustible matter.

Incineration equipment should be carefully chosen on the basis of the available resources and the local situation. Three basic kinds of incineration technology are of interest for treating health care waste:

- Double-chamber pyrolytic incinerators, which may be especially designed to burn infectious health care waste
- Single-chamber furnaces with static grate, which should be used only if pyrolytic incinerators are not affordable
- Rotary kilns operating at high temperature, capable of causing decomposition of genotoxic substances and heat-resistant chemicals

Pyrolytic incinerators—The most reliable and commonly used treatment process for health care waste is pyrolytic incineration, also called “controlled-air incineration” or “double-chamber incineration.” The pyrolytic incinerators may be especially designed for hospitals. The pyrolytic incinerator comprises a pyrolytic chamber and a post-combustion chamber and functions as follows:

1. In the pyrolytic chamber, the waste is thermally decomposed through an oxygen-deficient, medium-temperature combustion process (800°C to 900°C), producing solid ashes and gases. The pyrolytic chamber includes a fuel burner, which is used to start the process. The waste is loaded in suitable waste bags or containers
2. A fuel burner in the post-combustion chamber using an excess of air to minimize smoke and odors burns the gases produced in this way at high temperatures (900°C to 1200°C)

Larger pyrolytic incinerators (capacity: 1 to 8 tons/day) are usually designed to function on a continuous basis. They also may be capable of fully automatic operation, including loading of waste, removal of ashes, and internal movement of burning waste.

Adequately maintained and operated pyrolytic incinerators of limited size, as commonly used in hospitals, do not require exhaust-gas-cleaning equipment. Their ashes will contain less than 1% unburnt material, which can be disposed of in landfills. However, to avoid dioxin production, no chlorinated plastic bags (and preferably no other chlorinated compounds) should be introduced into the incinerator and therefore none should be used for packaging waste before its incineration.

Capital costs for pyrolytic incinerators, suitable for treating health care waste, vary widely. The operating and maintenance costs for a small-scale hospital pyrolytic incinerator may reach about \$19,000 per ton of waste incinerated.

Rotary kilns—A rotary kiln, which comprises a rotating oven and a post combustion chamber, may be used specifically to burn chemical wastes, and it is suited for use as a regional health care waste incinerator. The kiln rotates two to five times per minute and is charged with waste at the top. Ashes are evacuated at the bottom end of the kiln. The gases produced in the kiln are heated to high temperatures to burn off gaseous organic compounds in the post combustion chamber and typically have a residence time of two seconds. Rotary kilns may operate continuously and are adaptable to a wide range of loading devices. Those designed to treat toxic wastes should be operated by specialist waste disposal agencies and should be located in industrial areas.

Incineration in Municipal Incinerators

It is economically attractive to dispose of infectious health care waste in municipal incinerators if these are located reasonably close to hospitals. As the heating value of health care waste is significantly higher than that of domestic refuse, the introduction of relatively small quantities of health care waste will not affect the operation of a municipal incinerator. Municipal incinerators are usually of a double chamber design, with an operating temperature of 800°C in the first combustion chamber and gas combustion in the second chamber at temperatures of, typically, 1000°C–1200°C.

A number of rules and recommendations apply to the disposal of health care waste in municipal facilities:

1. When health care waste is delivered to the incineration plant, the packaging should be checked to ensure that it is undamaged.
2. Health care waste should not be packed in cylindrical containers because these could roll on the grids where they are placed for combustion.
3. Facilities should be available at the incineration site for the cleaning and disinfection of transportation equipment, including vehicles.
4. Deposit of health care waste in the normal reception bunker is not recommended: There is a risk of waste bags being damaged during transfer to the furnace by the overhead crane. Health care waste therefore should be loaded directly into the furnace.
5. Use of an automatic loading device for bags and containers of health care waste, rather than manual loading, would protect the safety of workers.
6. Health care waste should not be stored for more than 24 hours at an incineration plant; longer storage would require cooling facilities to prevent the growth of certain pathogens and the development of odors.⁷⁾ The combustion efficiency should be

checked. It should be at least 97% during incineration of health care waste.⁸⁾ Health care waste should be introduced into the furnace only when the normal conditions of combustion have been established, never during startup or shut-down of the combustion process.

9. The process should be designed to prevent contamination of ashes or wastewater by the health care waste.

Incineration Options that Meet Minimum Requirements

If a pyrolytic incinerator cannot be afforded, health care waste may be incinerated in a static-grate, single-chamber incinerator. This type of incinerator treats waste in batches while loading and de-ashing operations are performed manually. The combustion is initiated by the addition of fuel and should then continue unaided.

Atmospheric emissions of that type of incinerators usually include acid gases such as sulfur dioxide, hydrogen chloride, and hydrogen fluoride, black smoke, fly ash (particulate), carbon monoxide, nitrogen oxide, heavy metals, and volatile organic chemicals. To limit these emissions, the incinerator should be properly operated and carefully maintained, and sources of pollution should be excluded from the waste to be incinerated whenever possible.

The drum incinerator is the simplest form of single-chamber incinerator. It should be used only as a last resort, as it is difficult to burn the waste completely without generating potentially harmful smoke. The option is appropriate only in emergencies during acute outbreaks of communicable diseases and should be used only for infectious waste.

The drum incinerator should be designed to allow the intake of sufficient air and the addition of adequate quantities of fuel is essential, to keep the temperature as high as possible. A 210-liter steel drum should be used, with both ends removed; this will allow the burning of one bag of waste at a time. To operate the drum incinerator, a fire should first be established on the ground underneath it. One bag of waste should be lowered in to the drum. Tying the bag to a stick with string will help to avoid burns. Wood should be added to the fire until the waste is completely burned. After burning is complete, the ashes from both the fire and the waste itself should be collected and buried safely inside the premises of health care facilities.

The efficiency of this type of incinerator may reach 80%–90% and may thus result in destruction of 99% of microorganisms and a dramatic reduction in the volume and weight of waste. However, many chemical and pharmaceutical residues will persist if temperatures do not exceed 200°C. In addition, the process will cause massive emission of black smoke, fly ash, and potentially toxic gases.

Land Disposal

If a municipality or medical authority genuinely lacks the means to treat wastes before disposal, the use of a landfill must be regarded as an acceptable disposal route. Allowing health care waste to accumulate at hospitals or elsewhere constitutes a far higher risk of the transmission of infection than careful disposal in a municipal landfill, even if the site is not designed to the standard used in higher-income countries. The primary objections to landfill disposal of hazardous health care waste, especially untreated waste, may be cultural or religious or based on a perceived risk of the release of pathogens to air and water, or on the risk of access by scavengers.

Safe Burial in Hospital Premises

In health care establishments that use minimal programs for health care waste management, particularly in remote locations, in temporary refugee encampments, or in areas experiencing exceptional hardship, the safe burial of waste on hospital premises may be the only viable option available at the time. However, the hospital management should establish certain basic rules:

1. Access to the disposal site should be restricted to authorized personnel only.
2. The burial site should be lined with a material of low permeability, such as clay, if available, to prevent pollution of any shallow groundwater that may subsequently reach nearby wells.

Collection and Disposal of Wastewater

Characteristics and Hazards of Wastewater from Health Care Establishments

Wastewater from health care establishments is of a similar quality to urban wastewater, but may also contain various potentially hazardous components, discussed below.

Microbiological Pathogens

The principal area of concern is wastewater with a high content of enteric pathogens, including bacteria, viruses, and helminths, which are easily transmitted through water. Contaminated wastewater is produced by wards that treat patients with enteric diseases and is a particular problem during outbreaks of diarrhea disease.

Hazardous Chemicals

Small amounts of chemicals from cleaning and disinfection operations are regularly discharged into sewers.

Pharmaceuticals

Small quantities of pharmaceuticals are usually discharged to the sewers from hospital pharmacies and from the various wards.

Radioactive Isotopes

Small amounts of radioactive isotopes will be discharged into sewers by oncology departments but should not pose any risk to health.

Related Hazards

In some developing and industrializing countries, outbreaks of cholera are reported periodically. Sewers of the health care establishments where cholera patients are treated are not always connected to efficient sewage treatment plants, and sometimes municipal sewer networks do not even exist. Although links between the spread of cholera and unsafe wastewater disposal have not been sufficiently studied or documented, they have been strongly suspected; for example, during recent African outbreaks (e.g., the Democratic Republic of the Congo and Rwanda), and during the 1991–92 cholera epidemic in southern America. In collection and disposal of wastewater, little information is available on the transmission of other diseases through the sewage of health care establishments.

In developed countries, water use is commonly high, and the sewage therefore greatly diluted; effluents are treated in municipal treatment plants, and no significant health risks should be expected, even without further specific treatment of these effluents. Only in the unlikely event of an outbreak of acute diarrhea diseases should excreta from patients be collected separately and disinfected. In developing countries, where there might be no connection to municipal sewage networks, discharge of untreated or inadequately treated sewage to the environment inevitably will pose major health risks.

The toxic effects of any chemical pollutants contained in wastewater on the active bacteria of the sewage purification process may give rise to additional hazards.

Wastewater Management

The basic principle underlying effective wastewater management is a strict limit on the discharge of hazardous liquids to sewers.

Connection to a Municipal Sewage Treatment Plant

In countries that do not experience epidemics of enteric disease and that are not endemic for intestinal helminthiasis, it is acceptable to discharge the sewage of health care establishments to municipal sewers without pretreatment, if the following requirements are met:

- The municipal sewers are connected to efficiently operated sewage treatment plants that ensure at least 95% removal of bacteria
- The sludge resulting from sewage treatment is subjected to anaerobic digestion, leaving no more than one helminthes egg per liter in the digested sludge.
- The waste management system of the health care establishment maintains high standards, ensuring the absence of significant quantities of toxic chemicals, pharmaceuticals, radionuclides, cytotoxic drugs, and antibiotics in the discharged sewage.
- Excreta from patients being treated with cytotoxic drugs may be collected separately and adequately treated (as for other cytotoxic waste).

If these requirements cannot be met, the wastewater should be managed and treated as recommended below in the section on on-site treatment or pretreatment of wastewater.

Under normal circumstances, the usual secondary bacteriological treatment of sewage, properly applied, complemented by anaerobic digestion of sludge, can be considered to be sufficient. During outbreaks of enteric disease, however, or during critical periods (usually during the summer because of warm weather, and during the autumn because of reduced river water flow), effluent disinfection by chlorine dioxide (ClO₂) or by any other efficient process is recommended. If the final effluent is discharged into coastal waters close to shellfish habitats, disinfection of the effluent will be required throughout the year.

When the final effluents or the sludge from sewage treatment plants are reused for agricultural or aquacultural purposes, the safety recommendations of the relevant WHO guidelines should be respected. (See following section.)

OnSite Treatment or Pretreatment of Wastewater

Many hospitals (in particular, those that are not connected to any municipal treatment plant) have their own sewage treatment plants.

Efficient on-site treatment of hospital sewage should include the following operations:

- Primary treatment
- Secondary biological purification. Most helminthes will settle in the sludge resulting from secondary purification, together with 90%–95% of bacteria and a significant percentage of viruses; the secondary effluent thus will be almost free of helminthes, but will include infective concentrations of bacteria and viruses.
- Tertiary treatment. The secondary effluent probably will contain at least 20 mg/liter of suspended organic matter, which is too high for efficient chlorine disinfection. It therefore should be subjected to a tertiary treatment, such as lagooning; if no space is available for creating a lagoon, rapid sand filtration may be substituted to produce a tertiary effluent with a much-reduced content of suspended organic matter (<10mg/litre).
- Chlorine disinfection. To achieve pathogen concentrations comparable to those found in natural waters, the tertiary effluent will be subjected to chlorine disinfection, to the breakpoint. This may be done with chlorine dioxide (which is the most efficient), sodium hypochlorite, or chlorine gas.
- Ultraviolet light disinfection

Disinfection of the effluents is particularly important if they are discharged into coastal waters close to shellfish habitats, especially if local people are in the habit of eating raw shellfish

The sludge from the sewage treatment plant requires anaerobic digestion to ensure thermal elimination of most pathogens. Alternatively, it may be dried in natural drying beds and then incinerated together with solid infectious health care waste. On-site treatment of hospital sewage will produce a sludge that contains high concentrations of helminthes and other pathogens.

According to the relevant WHO guidelines, the treated wastewater should contain no more than one helminthes egg per liter and no more than 1000 fecal coliforms per 100 ml if it is to be used for unrestricted irrigation. It is essential that the treated sludge contain no more than one helminthes egg per kilogram, and no more than 1000 fecal coliforms per 100g. The sludge should be applied to fields in trenches and then covered with soil (WHO, 1997).

Options for Establishments that Apply Minimal Waste Management Programs

Lagooning

In a region or an individual health care establishment that cannot afford sewage treatment plants, a lagooning system is the minimal requirement for treatment of wastewater. The system should comprise two successive lagoons to achieve an acceptable level of purification of hospital sewage.

Lagooning may be followed by infiltration of the effluent into the land, benefiting from the filtering capacity of the soil. There is no safe solution for disposal of sewage from a hospital that cannot afford a compact sewage treatment plant.

Minimal Safety Requirements

For health care establishments that apply minimal programs and that are unable to afford any sewage treatment, the following measures should be implemented to minimize health risks:

- Patients with enteric diseases should be isolated in wards where their excreta can be collected in buckets for chemical disinfection; this is of the utmost importance in case of cholera outbreaks, for example, and strong disinfectants will be needed.
- No chemicals or pharmaceuticals should be discharged into the sewer.
- Sludges from hospital cesspools should be dehydrated on natural drying beds and disinfected chemically (e.g., with sodium hypochlorite, chlorine gas, or, preferably, chlorine dioxide).
- Sewage from health care establishments never should be used for agricultural or aquacultural purposes.
- Hospital sewage should not be discharged into natural water bodies that are used to irrigate fruit or vegetable crops, to produce drinking water, or for recreational purposes.

Small-scale rural health care establishments that apply minimal waste management programs may discharge their wastewater into the environment.

One acceptable solution would be natural filtration of the sewage through porous soils, but this must take place outside of the catchment area of aquifers that are used to produce drinking water or to supply water to the health care establishment.

Sanitation

In many health care establishments in developing countries, patients have no access to sanitation facilities. Excreta are usually disposed of in the environment, creating a high direct or indirect risk of infection to other people. Human excreta are the principal vehicle for the transmission and spread of a wide range of communicable diseases, and excreta from hospital patients may be expected to contain far higher concentrations of pathogens, and therefore to be far more infectious than excreta from households. This underlines the prime importance of providing access to adequate sanitation in every health care establishment, and of handling this issue with special care. The fecal-oral transmission route and other routes such as penetration of the skin must be interrupted to prevent continuous infection and reinfection of the population.

Vector Control

Hygiene is fundamentally important in the hospital environment. Its importance should not be limited to the concepts of cleaning, disinfection, and sterilization. It should reach wider concepts, as the one of rationalization of hospital garbage and special cares. For instance, it should be guaranteed that eating in the hospital environment should only occur in hospital rooms, cafeterias, and snack bars. It is extremely important to apply continuous and in-service education programs. These programs should reach employees, patients, and visitors. This part is designated to the health care professionals entrusted with the recognition, evaluation, and control of vectors of diseases in the hospital environment.

Rodents

The mouse and rat are the most harmful rodents. The most common species are the mouse (*Mus musculus*), the lining mouse or domestic mouse (*Rattus rattus*), and the sewer rat (*Rattus norvegicus*). All live close to man, in homes, barns, docks, ships and garbage deposits. They are well-known bearers of diseases, intestinal parasites, and fleas. They are especially responsible for the transmission of bubonic plague, leptospirosis (*Leptospira* sp.), fever of Haverhill (*Streptobacillus moniliformes*). It still transmits "SODOKU" (*Spirillum minus*), characterized by a hardened ulcer around the point of the bite, recurrent fever, and exanthema cutaneous.

Knowing some characteristics of these rodents, as follows, will aid in their recognition:

- Their vision is weak and thus they move in contact with the walls, leaving marks from the dirt of their bodies.
- They have an excellent sense of smell, so they do not return to places where other mice have died.
- They defecate in the place where they have eaten. The species can be determined from the dimensions of the feces.

The evaluation of the amount of existent rodents in a certain place is made by considering the damages that they cause. Specialist professionals of pest control and sanitation can better quantify this. The evaluation is concluded with the location of the nest.

During the critical phase (infestation), control is accomplished through the use of rat venom in bait form. This venom normally acts by inhibiting blood coagulation, factors leading to the death of the mice from hemorrhages, days after the ingestion. Bait should be distributed close to walls. After the critical phase, control can be established with the maintenance of hygiene, eating in appropriate places in the hospital, and improvement in the quality of the sewer.

Insects

The insects are the dominant group of animals in the earth (Borror, 1964). They surpass in number all other terrestrial animals and can be seen everywhere. Many insects are extremely valuable to man, particularly in crop pollination. They also produce honey, beeswax, silk, and other products of commercial value. Insects also have been useful in medical and scientific research. However, some insects are noxious and human and animal annually, related to agricultural crops, stored products, and human and animal health. They have existed on earth for more than 300 million years. They adapt to several habitat types. Many possess social organization and high reproductive capacity; and each generation can last from days to years.

Cockroaches

Cockroaches belong to the order *Orthoptera* and the suborder *Blattidae*. They have an oval form and are flat. They are omnivorous, and they have domestic habits. The most common species are the American cockroach and Germanic *Blattella*. Cockroaches are not known as specific vectors of diseases. However, they feed off a great variety of products, contaminating victuals. They have an unpleasant scent and frequently become serious pests.

Fleas

Fleas belong to the order *Siphonaptera*. They are blood-feeding insects without wings. The bites of some species are quite irritating. Some serve as vectors of diseases, other as intermediate hosts of certain taenia. Some species penetrate into the skin of animals and of man.

The flea's body is flattened sidelong; some fleas have eyes, and some do not. They do not have specific hosts, and they can feed on several animals. They can live for up to one year and can survive several weeks without feeding. They lay their eggs in the ground or in the nest of the host.

Fleas transmit to man three plagues: The bubonic, the pneumonic, and the septicemia. The most important disease transmitted by fleas is bubonic plague, an infectious disease caused by the *Bacillus pasteurilla* pests. It is a disease of rodents and is transmitted from one to another by way of fleas.

Three modes of transmission are known: Regurgitation of bacilli during a bite by an infested flea, scrubbing on the skin, and ingestion of infected fleas.

Lice

Lice belong to the order *Anoplura*. They are ectoparasites that feed on blood. Two species infest man: The head louse (*Pediculus humanus capitis*) and the corporal louse (*Pediculus humanus corporis*). The adults' length varies from 2.5–3.5 millimeters; the head louse lays its eggs in the hair of the head and body and in the seams of clothes; its reproductive cycle lasts about one month; it feeds frequent, and the meal lasts for minutes.

Head lice are transmitted person to person by the casual use of combs, hairbrushes, and caps. Body lice are transmitted through personal clothes or beds; they can migrate during the night, from one place to another. It is an important vector of man's diseases, epidemic typhoid fever being the most important disease. Often it attains serious epidemic proportions and can cause a mortality rate of up to 70%. Another important disease is recurrent fever, the transmission of which is made when the infected louse is squeezed against the skin. The feces and the bites are not infecting. Another disease, known as "fever of the trenches," was common during World War I.

Flies and Black Flies

Flies and black flies belong to the order *Dipterous*. They constitute one of the largest orders of insects, and its representatives are plentiful in individuals. Species are founded almost everywhere. Most of the *Dipterous* are relatively small insects with soft bodies; some have great economic importance. The black flies of the stables and others are hematophagous and they constitute severe plagues to the man and animals.

Many of the *Dipterous hematophagous* and *saprophagous*, as the domestic fly and the blowflies, are important vectors of diseases. The organisms that cause malaria, yellow fever, filariasis, sleeping sickness, typhoid fever, and dysentery are transported and disseminated by dipterous. Sleeping sickness is a deadly disease and currently affects as many as half a million people in sub-Saharan Africa, while an estimated 60 million people are at risk of contracting the disease in 36 countries.

Control

The control of insects can be made first through good hygiene practices in the hospital environment. Favorable results can be obtained by using screens in the windows of kitchens or places where they can obtain food. Pesticides are applied periodically in openings, dark places, and baseboards—the usual hiding places. An effective chemical product, piretróide, acts upon the neuron membrane, causing a chemical imbalance in the concentrations of sodium and potassium.

A specialist team should be established to control vectors in the hospital environment. Collaboration of all hospital departments promotes the success of the control program. This team should relate to the local health authorities. If outside companies are utilized, they should be specialized and registered in their areas of specialization.

The risks of pesticide application without appropriate criteria include low efficiency, human toxicity, and increased resistance of the insects. Effective control of vectors in the hospital environment requires a knowledge of the vector's habitat, alimentary habits, reproductive cycle, and other factors that could serve as vulnerability points.

Finally, the basic strategy of intervention should consist of treating the existent breeding places, expelling the insects, and impeding their return to these places for recolonization.

Clinical Engineering and Medical Equipment

Infection control related to medical equipment is important to nurses, physicians, and clinical engineers. Nurses and physicians are concerned with occupational health, and clinical engineers are concerned with evaluations of devices and sterilization processes.

Below, several medical devices and their relationship to infection control are described.

Ventilators

Ventilators breathe for patients who cannot breathe on their own because of such afflictions as disease, trauma, and congenital defects. Ventilators are connected to patients by means of such devices as breathing circuits and endotracheal tubes. Problems associated with ventilators include wounds caused during the patient's intubation, excessive pressure in the lungs, safety valves damaged or not adjusted, cross contamination, and infection. Usually, the breathing circuits are manufactured of plastic material and sterilized by ethylene oxide or a liquid sterilant. Most international manufacturers offer breathing circuits made of material that can be steam sterilized. When buying a breathing circuit, it is necessary to consider its material in order to minimize additional costs of sterilization.

Heated Humidifiers

Adequate humidity and temperature of the gas mixture to the lungs of a patient is accomplished through the use of a heated humidifier in the patient's breathing circuit. In normal respiration, the mouth, nostrils, and pharynx heat and humidify inhaled air and retain heat and vapors during exhalation. When the patient is under tracheostomy or using endotracheal tubes, this process of natural humidification does not occur. Heated humidifiers help to alleviate dehydration, provide comfort to membranes of respiratory system, and prevent loss of body heat.

The most common problems relating to this technology are hyperhydration, dehydration, hypothermia, hyperthermia, thermal lesions of the mucous membranes, melting of breathing circuits, and infection. Infection is a concern with all humidifiers and is usually the result of the inadequate or inappropriate handling, cleaning, and disinfecting of breathing circuits (see Figure 114-4).

Electrosurgical Units

During surgical procedures, surgeons use electrosurgical units (ESU) to cut and coagulate tissues. ESUs generate electric current at high frequency at the end of an active electrode. This current cuts and coagulates tissue. The advantages of this technology over the conventional scalpel are simultaneous cutting and coagulating and ease of use in several procedures (including surgical endoscopy procedures).

The most common problems are burns, fire and electric shock. This type of burn usually occurs under the electrode of ECG equipment, under the ESU grounding, also known as return or dispersive electrode), or on various parts of the body that may be in contact with a return path for the ESU current, e.g., arms, chest, and legs. Fires occur when flammable liquids come in contact with sparks from the ESU in the presence of an oxidant. Usually these accidents begin the development of an infectious process in the place of the burn. This can bring serious consequences to the patient and usually increase the patient's stay in the hospital.

Aspirators

Aspirators are used to aspirate substances such as blood, tissue, and fat. Aspirator maintenance procedures should consider biological hazards. Engineering and nursing must develop a plan to ensure that equipment is free from pathogenic microorganisms when delivered to maintenance. Mobile aspirators can pollute the environment because they can discharge particulate material.

Infant Incubators

An infant incubator is a closed atmosphere where temperature, humidity, and oxygen concentration are controlled. Usually, the values of relative humidity are not controlled and its value inside it will depend on the values of humidity found in the atmosphere outside the incubator. Humidification devices integral to incubators or used in conjunction with them may harbor pathogenic organisms. Clinical engineering should work with nursing

Figure 114-4 Representation of a ventilator breathing circuit and its components.

to ensure that infant incubators are routinely cleaned and disinfected and that air filters are changed at appropriate intervals.

Anesthesia Equipment

Anesthesia machines are discussed in detail in Chapter 90. The contamination of any part of the breathing circuit, including the wye connector, face mask, and reservoir bag can spread hospital infection. The related to this equipment include infections of respiratory superior tract and lungs. The Centers for Disease Control and Prevention (CDC) recommends the use of high level disinfection of reusable breathing circuits between each patients use to prevent cross contamination. Universal agreement has not been reached on the advisability of using bacterial filters to prevent cross contamination between patients.

Nebulizers

Nebulizers administer aerosol medication to patients. Nebulizers therapy is particularly effective in treatment of cystic fibrosis, emphysema, bronchitis, and severe asthma, in which viscous secretions occur. The aerosol disperses these secretions, stimulates coughing and expectoration, and alleviates respiratory tract congestion. Compressed air and ultrasonic nebulizers are most frequently used and both produce aerosols capable of effectively carrying medication to the lungs.

Tuberculosis patients require special care. As aerosol treatment induces coughing it may also increase the potential for transmission of *M. tuberculosis*. Health care personnel should be particularly alert to prevent *M. tuberculosis* transmission where immunocompromised persons (e.g., HIV-infected persons) work or receive care especially if cough-inducing procedures, such as sputum induction and aerosolized pentamidine treatments are being performed.

M. tuberculosis is carried by airborne particles, or droplet nuclei, that can be generated when persons who have pulmonary or laryngeal TB sneeze, cough, speak, or sing. The particles are about 1 mm in diameter and normal air currents can keep them airborne for prolonged periods and spread them throughout a room or building. Infection occurs when a susceptible person inhales droplet nuclei containing *M. tuberculosis* and these droplet nuclei traverse the mouth or nasal passages, upper respiratory tract, and bronchi to reach the alveoli of the lungs. Once in the alveoli, the organisms are taken up by alveolar macrophages and spread throughout the body. Usually within 2–10 weeks after initial infection with *M. tuberculosis*, the immune response limits further multiplication and spread of the tubercle bacilli; however, some of the bacilli remain dormant and viable for many years.

Hemodialysis Units

The kidneys maintain body fluid and acid/base balance even as metabolic activity and external conditions change. Hemodialysis units are used to treat patients with compromised renal function and resultant retention of water and metabolites. Hemodialysis therapy removes ions and organic salts from the blood.

Infection is the most common complication and the largest causes of the morbid mortality associated with the use of hemodialysis units. The antigen of the hepatitis B (HBsAg) has been detected at several locations in hemodialysis centers including the control buttons of hemodialysis units. Consequently, application of strict measures and procedures that reduce infection risks should be used. Necessary measures to reduce this risk include disinfection and sterilization, hygiene and cleaning, maintenance, removal of residues, isolation precautions, and universal precautions. Water used in hemodialysis should be periodically tested to ensure that water treatment is adequate. In addition to performing their preventive maintenance routines, centers that use reverse osmosis equipment should tests at least once a year. See Chapter 115 for more information on water treatment in hemodialysis.

Hospital Engineering and Hospital Installations

Although some hospitals have hospital engineers, those that do not often employ clinical engineers to take care of infrastructure systems such as medical vacuum, compressed air, laundry and heating, ventilation, and air conditioning (HVAC).

Medical Vacuum

Medical vacuum is used to aspirate secretions and fluids from the human body during surgery or other medical and nursing procedures. Central vacuum generates a negative pressure in a piping network sufficient to aspirate secretions from the human body. The aspiration bottles retain the heaviest particles aspirated. Smaller and lighter particles in aerosols form are aspirated into the piping network of the vacuum system may reach the outside atmosphere. Filters on equipment and systems that connect to the medical vacuum system reduce the possibility of air contamination. For additional information on medical vacuum, see Chapter 110.

Vacuum system should be inspected and serviced as follows:

- Air analysis: Tests to determine the contamination level of the air coming from the pipe network. Bacteriology laboratory tests are recommended.
- Analysis of pollutants in the reservoir: The vacuum reservoir should possess an opening for easy access. This permits the inspection, cleaning and disinfecting of the internal mechanical structure of the reservoir, as well as the collecting of samples for microbiological analyses.
- Whenever possible, redundancy should be incorporated in vacuum piping systems be without turning it off. Two reservoirs interlinked by specially located piping and valves can achieve this end.
- Analysis of seal water: Some pump models need a certain volume of water to work. This water comes in contact with human body fluids in form of aerosols coming from the piping network. This water should not be reused unless appropriate treatment is received.

Vacuum systems should never be located near HVAC systems or medical air compressors lest these systems become contaminated by infectious agents released by the vacuum system.

Medical Compressed Air

Medical compressed air is mainly used to supply pure air directly to patients or to pneumatic systems of medical devices such as ventilators, anesthesia machines, and inhalation devices. It must be free of pathogenic microorganisms and other contaminants (see Chapter 110).

The air supplied should be dry because water can damage pneumatic circuits. Dry air is required for proper functioning of patient humidifiers.

Compressors should be located where intake air is of a high-quality. This reduces the risks of contamination of the piping network and the cost of filtration of air generated in the compression process. Independent of the generating source of air, the following maximum levels of pollutants are recommended: 19%–23% for oxygen, 5 ppm for carbon monoxide, 500 ppm for carbon dioxide, 5 ppm for nitrous oxide, and 1 mg/m³ for oil and other particles. Clinical engineering departments advise maintenance teams as to the special maintenance requirements of medical compressed air systems.

Laundry Equipment

To ensure that clothes and linens are cleaned and disinfected adequately, the laundry must have properly functioning steam and hot water generation systems. Temperature and steam pressure variances can reduce the effectiveness of certain products or chemical disinfectant agents. The clinical engineering department should contact the manufacturer of cleaning and disinfecting products in the laundry so that the optimal temperature and pressure of steam and hot water is achieved. The ventilation and exhaust systems of the laundry should be evaluated periodically. Exhaust should be directed to contaminated areas and intake air obtained from clean areas.

Heating, Ventilation, and Air Conditioning

Heating, ventilation, and air conditioning (HVAC) systems are often used in hospitals at least in the operating rooms (OR), intensive care unit (ICU), and other areas where patients are receiving care. (For a discussion of HVAC, see Chapter 108.)

Clinical engineering should be concerned with ensuring that all air conditioning variables are controlled, especially the purity of the air. In systems that make use of cooling towers and reservoir of water to air humidification, verification of the microbiologic quality of the water stored in these reservoirs is necessary because they can shelter pathogenic microorganisms. The purity of the air should be assessed by monitoring particulate material in the air every six months. Understanding that a filter's useful life is influenced by the quality of the outside air, the efficacy of air filters can be determined by measurement of differential pressure across the filters.

Conclusion

The activities of clinical engineering in infection control are varied. Clinical engineers should consider this chapter to be an introduction to the contribution that they can make in this field and should realize that much more can be accomplished. Clinical engineers are particularly well suited, by education and experience, to collaborate with other health care professionals in planning projects, training activities, construction projects, acquisition of equipment and systems, and working to control the spread of infection.

Glossary

Adherence: The behavior of patients when they follow all aspects of the treatment regimen as prescribed by the medical provider. Also refers to the behavior of health care workers and employers when they follow all guidelines pertaining to infection control.

Aeration: The method by which absorbed ethylene oxide gas is allowed to dissipate from sterilized items by the use of warm air circulation in a specially designed enclosed cabinet.

Aerosol: The droplet nuclei that are expelled by an infectious person (e.g., by coughing or sneezing); these droplet nuclei can remain suspended in the air and can transmit *M. tuberculosis* to other persons.

AIA: The American Institute of Architects, a professional body that develops standards for building ventilation.

Air changes: The ratio of the volume of air flowing through a space in a certain period of time (i.e., the airflow rate) to the volume of that space (i.e., the room volume); this ratio is usually expressed as the number of air changes per hour (ACH).

Air mixing: The degree to which the air supplied to a room mixes with the air already in the room, usually expressed as a mixing factor. This factor varies from 1 (for perfect mixing) to 10 (for poor mixing), and it is used as a multiplier to determine the actual airflow required (i.e., the recommended ACH multiplied by the mixing factor equals the actual ACH required).

Alveoli: The small air sacs in the lungs that lie at the end of the bronchial tree; the site where carbon dioxide in the blood is replaced by oxygen from the lungs and where TB infection usually begins.

Anteroom: A small room leading from a corridor into an isolation room. This room can act as an airlock, preventing the escape of contaminants from the isolation room into the corridor.

Area: A structural unit (e.g., a hospital ward or laboratory) or functional unit (e.g., an internal medicine service) in which health care workers provide services to, and share air with, a specific patient population or work with clinical specimens that may contain viable *M. tuberculosis* organisms. The risk for exposure to *M. tuberculosis* in a given area depends on the prevalence of TB in the population served and the characteristics of the environment.

Asepsis: Absence of infectious organisms.

ASHRAE: The American Society of Heating, Refrigerating and Air Conditioning Engineers, Inc., a professional body that develops standards for building ventilation.

Asymptomatic: Without symptoms, or producing no symptoms of disease.

Bioburden (N_0): The number of microorganisms that will be admitted prior to begin of the configuration process. It is the initial population of spores to be reduced.

Biological indicator: A sterilization process monitoring device that is commercially prepared with a known population of highly resistant spores to test the effectiveness of a sterilization method. The indicator is used to demonstrate that the conditions necessary to achieve sterilization were met during the cycle being monitored.

Bronchoscopy: A procedure for examining the respiratory tract that requires inserting an instrument (a bronchoscope) through the mouth or nose, and into the trachea. The procedure can be used to obtain diagnostic specimens.

Cavity: A hole in the lung, resulting from the destruction of pulmonary tissue by TB or other pulmonary infections or conditions. TB patients who have cavities in their lungs are referred to as having "cavitary disease," and they are often more infectious than TB patients without cavitary disease.

Chemotherapy: Treatment of an infection or disease by means of oral or injectable drugs.

Contact: A person who has shared the same air with a person who has infectious TB for a sufficient amount of time to allow possible transmission of mycobacterium tuberculosis (*M. tuberculosis*).

Culture: The process of growing bacteria in the laboratory so that organisms can be identified.

Chemical indicator: A sterilization monitoring device (e.g., chemically treated paper, pellets sealed in a glass tube, or pressure-sensitive tape) that is used to monitor certain parameters of a sterilization process by means of a characteristic color change.

Cleaning: This is the process (also known as "low level inactivation") in which a biocide inactivates vegetative bacteria, lipid-enveloped viruses, and fungi only.

Commissioning: Obtaining and documenting evidence that equipment has been provided and installed in accordance with its specifications and that it functions within predetermined limits when operated in accordance with its operational instructions.

Concurrent disinfection: Done after the expulsion of infectious material from the body of the patient to an area or equipment.

Contamination: Transference of an infectious agent to an organism or substance. At this point, there is no infection process.

Control (risks): To adopt technical, administrative, preventive or corrective measurements of several natures, which tend to eliminate or to lessen the existent risks in the workplace.

Critical devices: Devices that carry a high risk of infection associated with their use as they are introduced directly into human tissue. Examples include needles, catheters, and implants. These goods should be sterilized, protecting the patient against contamination. Devices used in the care of an infectious patient should be sterile before use on another patient.

Disinfection: An intermediate-level of inactivation, in which a biocide process inactivates all organisms but more resistant spores. Steam and hot water are the most common and efficient agents used in the health care environment.

Droplet nuclei: Microscopic particles (i.e., 1–5 μm in diameter) produced when a person coughs, sneezes, shouts, or sings. The droplets produced by an infectious TB patient can carry tubercle bacilli and can remain suspended in the air for prolonged periods of time and be carried on normal air currents in the room.

Drug resistance, acquired: A resistance to one or more anti-TB drugs that develops while a patient is receiving therapy and that usually results from the patient's nonadherence to therapy or the prescription of an inadequate regimen by a health care provider.

Drug resistance, primary: A resistance to one or more anti-TB drugs that exists before a patient is treated with the drug(s). Primary resistance occurs in persons exposed to, and infected with, a drug resistant strain of *M. tuberculosis*.

D-Value: The D-value is defined as the time required to reduce the microbial population by one decimal or one log unit. It expresses the heat resistance of the microorganism (see Figure 114-5).

Endemy: Habitual incidence of an infectious agent or a disease in a determinate area. It can mean the usual prevalence of a determinate disease in this area.

Edotoxins: High molecular complexes from the outer cell membrane of Gram-negative bacteria.

Evaluation of risks: Quantification and verification, in agreement with certain techniques, the magnitude of the risk (e.g., calculating or measuring air change rate in an environment and comparing with standards).

Event-related sterility: Shelf life based on the quality of the packaging material, storage conditions during transportation, and amount of handling of the item.

Exposure: The condition of being subjected to something (e.g., infectious agents) that could have a harmful effect. A person exposed to *M. tuberculosis* does not necessarily become infected. (See definition of "transmission.")

F_0 -Value: The lethality of the cycle expressed in terms of the equivalent time in minutes at a temperature of 121°C with reference to micro-organisms possessing a Z-Value of 10°C.

Fixed room air HEPA recirculation systems: Nonmobile devices or systems that remove airborne contaminants by recirculating air through a HEPA filter. These may be built into the room and permanently may be ducted, or they may be mounted to the wall or ceiling within the room. In either situation, they are fixed in place and are not easily movable.

Fomites: Linens, books, dishes, or other objects used or touched by a patient. These objects are not involved in the transmission of *M. tuberculosis*.

Gastric aspirate: A procedure sometimes used to obtain a specimen for culture when a patient cannot cough up adequate sputum. A tube is inserted through the mouth or nose and into the stomach to recover sputum that was coughed into the throat and then swallowed. This procedure is particularly useful for diagnosis in children, who are often unable to cough up sputum.

HEPA: Stands for "high efficiency particulate air filter." A specialized filter that is capable of removing 99.97% of particles 0.3 μm in diameter and that may assist in controlling the transmission of *M. tuberculosis*. Filters may be used in ventilation systems to remove particles from the air, or in personal respirators to filter air before it is inhaled by the person wearing the respirator. The use of HEPA filters in ventilation systems requires expertise in installation and maintenance.

Human immunodeficiency virus (HIV) infection: Infection with the virus that causes acquired immunodeficiency syndrome (AIDS). HIV infection is the most important risk factor for the progression of latent TB infection to active TB.

Immunosuppression: A condition in which the immune system is not functioning normally (e.g., severe cellular immunosuppression resulting from HIV infection or immunosuppressive therapy). Immunosuppressed persons are at greatly increased risk for developing active TB after they have been infected with *M. tuberculosis*. No data are available regarding whether these persons are also at increased risk for infection with *M. tuberculosis* after they have been exposed to the organism.

Infection: The condition in which organisms capable of causing disease (e.g., *M. tuberculosis*) enter the body and elicit a response from the host's immune defenses. TB infection may or may not lead to clinical disease. Penetration and development or multiplication of an infectious agent in the human or animal organism. An immunologic reaction should occur.

Infectious: Capable of transmitting infection. When persons who have clinically active pulmonary or laryngeal TB disease cough or sneeze, they can expel droplets containing *M. tuberculosis* into the air. Persons whose sputum smears are positive for AFB are probably infectious.

Infectious agent: Organism capable of causing an infection or infectious disease.

Lethality: Characterization of the performance of a sterilization cycle by a parameter known as " F_0 -Value."

Master plan for validation: A plan comprising an introduction; definitions and terminology; organization and responsibility; time schedule; objects to be validated or not

Figure 114-5 Microbial death rate curve: D-value.

validated; type of validation; document requirements; education requirements; and plan approval.

Multidrug resistant tuberculosis (MDR-TB): Active TB caused by *M. tuberculosis* organisms that are resistant to more than one anti-TB drug; in practice, it often refers to organisms that are resistant to both INH and rifampin, with or without resistance to other drugs. (See definitions of “drug resistance, acquired” and “drug resistance, primary.”)

Negative pressure: The relative air pressure difference between two areas in a health care facility. A room that is at negative pressure has a lower pressure than adjacent areas, which keeps air from flowing out of the room and into adjacent rooms or areas.

Nosocomial: An occurrence, usually an infection, that is acquired in a hospital and/or as a result of medical care.

Non-critical device: They are devices that come in contact with mucous membranes and nonintact skin and do not necessarily penetrate surfaces. Sterilization is not obligatory, although it is desirable because these devices (e.g., endotracheal tube, breathing equipment, and vaginal speculum) can become critical during procedures.

Operational qualification: The activities developed to control the limits of the process, parameters of the software, specifications of the raw material, procedures for operation of the process, change of control of the process, and calibration (e.g., pressure, temperature, and time).

Pathogenesis: The pathologic, physiologic, or biochemical process by which a disease develops.

Pathogenicity: The quality of producing or the ability to produce pathologic changes or disease. Some nontuberculous mycobacteria are pathogenic (e.g., *Mycobacterium kansasii*), and others are not (e.g., *Mycobacterium phlei*).

Portable room air HEPA recirculation units: Free-standing, portable devices that remove airborne contaminants by recirculating air through a HEPA filter.

Performance qualification: Obtaining and documenting evidence that the equipment as commissioned will produce acceptable product (“goods”) when operated in accordance with the operating instructions (“process specification”).

Pyrogens: Foreign bodies or material in the body that cause an increase in body temperature.

Qualification: Establishing documented evidence through appropriate testing that the finished product by a specified process (es) meet(s) all release requirements for functionality and safety.

Qualification of the installation: A control process that should include the characteristics of project of the equipment; conditions of the facilities (e.g., air, water, vapor, or electricity); calibration, preventive maintenance, cleaning; safety characteristics; software documentation; spare parts list; and environmental conditions.

Radiography: A method of viewing the respiratory system by using radiation to transmit an image of the respiratory system to film. A chest radiograph is taken to view the respira-

tory system of a person who is being evaluated for pulmonary TB. Abnormalities (e.g., lesions or cavities in the lungs, and enlarged lymph nodes) may indicate the presence of TB.

Recirculation: Ventilation in which most or all of the air that is exhausted from an area is returned to the same area or other areas of the facility.

Recognition (risks): To identify, characterize, and know to assign risk agents affecting patients and health care workers.

Resistance: The ability of some strains of bacteria, including *M. tuberculosis*, to grow and multiply in the presence of certain drugs that ordinarily kill them; such strains are referred to as “drug resistant strains.”

Room air HEPA recirculation systems and units: Devices (either fixed or portable) that remove airborne contaminants by recirculating air through a HEPA filter.

Saturated steam: Vapor whose temperature is the same as the water from which it originated.

Specimen: Any body fluid, secretion, or tissue sent to a laboratory where smears and cultures for *M. tuberculosis* will be performed (e.g., sputum, urine, spinal fluid, and material obtained at biopsy).

Sputum: Phlegm coughed up from deep within the lungs. If a patient has pulmonary disease, an examination of the sputum by smear and culture can be helpful in evaluating the organism responsible for the infection. Sputum should not be confused with saliva or nasal secretions.

Sputum induction: A method for obtaining sputum from a patient who is unable to cough up a specimen spontaneously. The patient inhales a saline mist, which stimulates a cough from deep within the lungs.

Sterilization: The absence of viable microorganisms, or the absence of living organisms. It kills all viable microorganisms, including spores.

Superheated Steam: Vapor whose temperature is above the point at which it became steam.

Semi-critical device: Devices that do not enter the body of the patient, but do contact the skin. Low risk of hospital infection is associated with the use of these items such as thermometers, silverware, and X-ray tables. Consequently, depending on the article and degree of contamination, intermediate or low level disinfection can be achieved by washing with water and soap.

Sterilization: High level inactivation, in which bacterial spores, acid-fast bacteria, other nonsporulating bacteria, fungi, and lipid-enveloped viruses are killed.

Surgical site infection: Infection involving body layers that have been incised.

TB infection: A condition in which living tubercle bacilli are present in the body, but the disease is not clinically active. Infected persons usually have positive tuberculin reactions, but they have no symptoms related to the infection and are not infectious. However, infected persons remain at lifelong risk for developing disease unless preventive therapy is given.

Transmission: The spread of an infectious agent from one person to another. The likelihood of transmission is directly related to the duration and intensity of exposure to *M. tuberculosis*. (See definition of “exposure.”)

Treatment failures: TB disease in patients who do not respond to chemotherapy and in patients whose disease worsens after having improved initially.

Tuberculosis (TB): A clinically active, symptomatic disease caused by an organism in the *M. tuberculosis* complex (usually *M. tuberculosis* or, rarely, *M. bovis* or *M. africanum*).

Terminal disinfection: Disinfection of clothes, personal use objects, medical devices, and immediate environment used by infected persons after death or suspension of isolation practices.

Ultraviolet germicidal irradiation (UVGI): The use of ultraviolet radiation to kill or inactivate microorganisms.

Ultraviolet germicidal irradiation (UVGI) lamps: Lamps that kill or inactivate microorganisms by emitting ultraviolet germicidal radiation, predominantly at a wavelength of 254 nm (intermediate light waves between visible light and X rays). UVGI lamps can be used in ceiling or wall fixtures or within air ducts of ventilation systems.

Figure 114-6 Z-value.

Validation: A documented procedure for obtaining, recording and interpreting data required to show that a process will consistently comply with predetermined specifications (configuration). For most heat sterilization, validation is considered as a total program, which consists of commissioning and performance qualification. It is a way of demonstrating, in accordance with the principles of good manufacturing practice (GMP), that any procedure, process, equipment, material, activity, or system actually leads to the expected result. It is used when sterilizer equipment is new; when there is a new product or load, and after changes or repair of the equipment.

Ventilation, dilution: An engineering control technique to dilute and remove airborne contaminants by the flow of air into and out of an area. Air that contains droplet nuclei is removed and replaced by contaminant free air. If the flow is sufficient, droplet nuclei become dispersed, diminishing their concentration in the air.

Ventilation, local exhaust: Ventilation that is used to capture and remove airborne contaminants by enclosing the contaminant source (i.e., the patient) or by placing an exhaust hood close to the contaminant source.

Virulence: The degree of pathogenicity of a microorganism as indicated by the severity of the disease produced and its ability to invade the tissues of a host. *M. tuberculosis* is a virulent organism.

Z-value: The Z-value (see Figure 114-6) is defined as the number of degrees temperature change to change the D-value by a factor of ten (10), or one log unit.

Water Systems in Health Care Facilities

Diógenes Hernández
PAHO/WHO Panama City, Panama

Water and its supply system are vital for the operation of health care facilities. An appropriate system for capture, storage, treatment, conditioning, use, and disposal of water must be present in order to prevent hazards to patients, health professionals, and the public in general. It is also necessary to protect the installed medical and other equipment and to prevent the fast deterioration that could result from the use of inadequate or contaminated water. Water is one of the most complex resources to manage in a health care facility, given its implications to the health of users, the operation of the facility, and the impact on health services in general.

The health care facility water system described here applies to both developed and developing countries. Nevertheless, differences do exist between countries regarding the availability of water through public distribution systems, water characteristics, mechanisms of capture and distribution in the facility, different uses, treatment prior to discharge, norms and standards at national and local levels, and regulations. In developed countries, agencies regulate and control water quality, particularly water used by health care facilities, although even developed countries include localities and rural areas with deficiencies in water supply quality. In developing countries, the lack of regulation and enforcement is common, even in urban centers. This situation is of great significance in countries vulnerable to natural disasters and extreme climatic phenomena. Natural disasters usually affect the availability, supply, and quality of the water, hindering the normal operation of a health facility. The vulnerability to natural disasters should be included as a critical factor in the process of planning a health care facility.

Water Use Cycle

The water system in a health care facility operates through several stages. It starts with the capture of the water from the municipal or public water supply system or from groundwater pumped from wells. Next, the storage, treatment, and conditioning occurs, depending on the expected use by clinical and support services. Water then passes through the distribution system or piping system in the facility. The demand for water by different services and the groups of users depends on many issues but must always consider potential risks and negative impacts of water use by people (e.g., infections) and equipment (e.g., fast deterioration and damage); the collection and treatment prior to its final disposal and discharge into the sewer system, rivers, and sea; and the possible environmental impact upon the water use cycle (e.g., contamination).

The water use cycle, from capture from the public distribution system up to disposal, has implications for the health of the people and the community. Environmental and economic implications are inherent in the use of water. Unfortunately, water is one of the most wasted resources, and studies on the costs of water wastage are rare. Unjustified water loss costs can be high and can include water that has been treated and conditioned in order to serve specific needs of the different health care facility clinical and support services. The water-management plan should include responses to emergency situations relating to contaminated supply, pipe system failure, sewage system malfunction, and a water rationing program.

Planning

The components and management of the water system should be defined and established when the health facility is planned and constructed. The remodeling or expansion of the physical plant presents a good opportunity to update and optimize the water system. If problems with the supply and the water quality for the different services or in critical circumstances exist, establish an emergency project to improve the water system and its management.

The size of the health facility, its level of specialization, the clinical services it provides, the installed medical and industrial equipment, and the environmental conditions of the area where the facility is located determine the amount and characteristics of water needed. The patterns of consumption and the class of treatment that should be given to the water before and after its use and prior to its final disposal to the public sewerage system should be also considered.

When planning a facility, evaluate the availability and options for water supply. Water is obtained from a public or municipal supply system, a private supplier, or a facility owned well. The first two options are most common in urban centers. The water is usually available 24 hours per day and has adequate levels of pressure and potability, making it suitable for immediate distribution and consumption within the facility. The third option is more common in rural areas or in remote regions without access to a public or municipal water supply system. In these cases, the implemented water supply system must guarantee the continuous availability of potable water at a pressure required for the operation of the facility.

Once the water supply source is defined, determine the chemical, physical, and biological characteristics of the water at the facility entry point. Depending on the values obtained by laboratory tests, and considering the foreseen uses by the different clinical and support areas of the facility, the water must be treated and conditioned to fit specific needs and demands. This is especially important in countries that do not have regulatory agencies or the capacity to monitor and control the water system.

Design Parameters

The study of the water demand should be conducted for each individual health care facility, but some basic indicators of consumption patterns can influence the design of the facility. As a rule, a regional hospital with an average of 250 beds providing four basic specialties will have a daily water consumption ranging from 450 to 600 liters per bed (PAHO/CEPIS, 1996). The estimate is adjusted upward if the health care facility includes services or equipment with high water demand.

The storage capacity for a health care facility depends on the specific local conditions related to water availability and distribution. The facility should have a storage capacity of three or four days in the event of a breakage or disruption in the main water line connected to the public network. If the facility does not have an adequate water supply on a regular basis, or is located in a region subject to natural disasters, the storage capacity should be increased. The facilities should have additional storage capacities when located in regions that are subject to long periods of drought, earthquakes, hurricanes, and cyclones, or prone to fire.

In designing a building's water distribution system or piping system, areas and services that are vital for the operation of the facility will require access to reliable water even during emergency situations or main supply water breakage or disruptions. These areas should be clearly defined, and the internal supply system should be designed and constructed so that these areas always have access to water. Points of access to water should also be provided in the noncritical sectors.

To guarantee adequate operation of the different areas and services in the facility, the water system should provide water in quantity, with the flow and pressure that people and equipment require. The operation of some equipment requires specific levels of pressure and flow, and the equipment will not function if these levels are not achieved or maintained. For example, some sterilizers have valves operated by water pressure. If the valves do not have the required water pressure for activation, the equipment will function erratically, or not at all.

If the public water supply system does not provide adequate pressure, or if necessary pressure can not be produced by gravity at the facility, some areas or sectors will not have enough pressure and flow. In such cases, alternate systems must be used to provide pressure and flow to the facility distribution system. This situation is more critical in taller buildings than in shorter ones.

Various engineering solutions can compensate for a lack of water pressure and flow. In health care facilities, especially those more horizontal than vertical, the use of elevated tanks is the most cost-effective way to achieve adequate pressure and flow. Elevated tanks should have 25%–30% of the total water storage capacity of the facility (FNH, 1981).

If the characteristics, location, or safety limitations do not allow water storage in elevated tanks, other options include the use of pressure tanks or hydro-pneumatic systems that provide pressure and flow as required at different areas of the facility.

Leaks are among the most common causes of water wastage. They happen due to the lack of an adequate preventive maintenance program to detect water leaks, decreased flow of water at delivery points, or a sudden and unexplained increase in water consumption by equipment or areas in the facility.

Water Treatment and Conditioning

Water provided by a municipal or public supply system is treated to meet local, national, or international standards. In the health care facility, water needs additional treatment and conditioning to meet the specific needs of the different users or services. The treatment procedure allows modification of the chemical composition of the water to minimize or eliminate chemical and biological contamination. This is of utmost importance in the health care facility, since some of the water will be used in clinical procedures, in direct contact with patients.

Before reaching the facility, the water has been treated by the municipality or the public water supply agency. Water from a facility-owned well should follow the same process as that used at municipality treatment plants. The following steps are the most common in the treatment process:

- Use of screens to remove large particulates at the intake point of the water supply.
- Reduction of turbidity and suspended matter. This part of the process is known as "clarification" and includes the addition of chemicals and the use of filters to remove particles larger than 25 microns.
- Reduction of the level of calcium and magnesium in a process known as "lime softening." The purpose of lime softening is to minimize the hardness of the water and further clarify it.
- Use of chlorine gas to disinfect water with the objective of killing bacteria. The chlorine level must be constantly monitored to ensure that no harmful levels reach the population.
- Adjust the water pH. Adjusted pH to between 7.5 and 8.0 prevents corrosion of water pipes and prevents leaching of lead into the water supply.

Once the water is delivered to the facility, it requires further treatment and conditioning to meet specific needs. The processes needed for further treatment vary with the end-user water requirements. Some treatment processes minimize risks and protect people, while others protect equipment. Some of the more common steps in on-site treatment and conditioning are as follows:

- Removal of particulates larger than 20 microns using sediment filtration, followed by removal of particulates larger than 10 microns using multimedia filtration.
- Adjustment of the water pH to prevent damage of pH sensitive materials. For example, adjustment of the pH to a level between 8.3 and 9.0 to prevent acid corrosion in boilers.
- Adding chemicals to soften the water in order to prevent hardness and the deposition of calcium, magnesium, ferrous, manganese and aluminum.
- Removal of chloramines, chlorines, and other low molecular weight organic chemicals using carbon beds.

Options to treat and condition water to suit specific needs are as follows:

- Use of filters. Sand filters remove turbidity but can not stop smaller impurities from passing through. Calcium carbonate calcite medium filters (also known as neutralizing filters) neutralize low-pH water. Activated carbon filters absorb low-molecular-weight organic chemicals and reduce chlorine or other halogens from water, but they do not remove any salts. There are several types of disposable filters to trap fine particles in the range of 1 to 100 microns, and ultra-filtration solutions remove particles in the range of 0.005 to 0.15 microns.
- Reverse osmosis. Reverse osmosis (RO) is a crossflow membrane separation process that removes virtually all organic compounds (Osmonics, 1992). A large selection of RO membranes is available to remove most particles and microorganisms.

For specific clinical procedures such as hemodialysis, water must be further conditioned for patient use (ECRI, 1999). Some methods for additional conditioning are as follows:

- Removal of salts, bacteria, pyrogens, metal ions, and particles using RO filters.
- Removal of charged particles such as metals and ions using deionization.
- Removal of bacteria, pyrogens, and particles larger than 0.05 microns using ultra-filtration.
- Use of ultraviolet light to kill microorganisms.

The main centers of water consumption should be determined based on the volume of water to be treated and the different requirements of end users. For example, water treatment plants must be built for water to be used in boilers for steam production and water used in the laundry service. However, for use in laboratories and clinical areas, water can be obtained by filtering, adding chemicals, or via distillation or the use of other special equipment.

In order to prevent outbreaks and nosocomial infections, protocols for water use should be part of a risk management program. Some common problems include infections from rinsing equipment with potable water, rinsing burn patients with tap water, and preparing baby formulas with tap water. A water quality control system should be implemented to avoid these problems.

End Users

Most health care facilities, have six major areas of water consumption: Sanitation; heating, ventilation, and air conditioning (HVAC); clinical and medical; laundry; food service; and miscellaneous uses. Sanitation and HVAC consume approximately 60% of the water in most facilities. Water use should not include the water required for the fire extinguishing system. This water is normally raw or untreated and it is stored in a separate tank.

The main end-users of water are patients and health care workers; clinical and support services; and the building itself. Most of the water used by patients and health care workers is for drinking and personal hygiene.

Water is used in many clinical services areas including the following:

- Clinical and pathology laboratories: Laboratories perform many operations with different types of equipment. Water is used and discharged by automated laboratory equipment, water baths, emergency showers, eyewash stations, and sinks. Some of the common pollutants in wastewater include solvents, mercury (Eppstein, 2000), zinc, and other heavy metals, strong acids and toxic chemicals, radionuclides, proteins, blood products, and body fluids.
- X-ray department: X-ray film processors need water. Ammonia and developer products are the most common chemical pollutants in film processor wastewater.

- Dental services: The hand-held tools in the dental care unit are the main users of water. The equipment water lines and cold wastewater from these tools become contaminated with microorganisms.
- Respiratory therapy department: Respiratory care equipment, nebulizers, and humidifiers are the devices that use the most water.
- Central supply and sterilization department: Water is used to clean and disinfect surgical instruments in conjunction with ethylene oxide sterilization. Some of the more common effluent pollutants are soap, detergent, disinfectants, and ethylene oxide.
- Operating theaters and emergency rooms: Water is used in surgical scrub sinks, where blood, body fluids, and glutaraldehyde can pollute the wastewater.
- Other areas with significant water usage include the pharmacy, for the preparation of formulas and parenteral solutions, and the physiotherapy unit, for hydrotherapy equipment. Both of these areas are susceptible to infection and contamination.

Water is used in the following support services areas:

- HVAC system: Cooling towers and humidifiers are the heavy consumers of non-potable water.
- Boiler House: Boilers and hot water tanks are the greatest water consumers in this area. Water treatment chemicals and oils are common pollutants.
- Laundry service: Washing machines are large consumers of water. An efficient operational policy supported by a preventive maintenance program can save water and the costs associated with its use and discharge in the laundry. Some of the more common pollutants are soaps, detergents, and bleaches are common pollutants.
- Food services and kitchen: Sinks, dishwashers, ice makers, and food preparation are users of water. Soaps, detergents, disinfectants, solvents, pesticides, and cleaning solutions are among the common pollutants.
- Medical waste incinerators: The most common pollutants are heavy metals and particulate matter.

Water used in the physical plant includes the following areas:

- Sanitary: Sinks, toilets, showers, and bathtubs are some of the appliances that consume water. Improper cleaning procedures will allow bacterial growth and contamination.
- Housekeeping: Cleaning and disinfecting will generate pollutants from soaps, detergents, cleaners, solvents, and disinfectants.
- Physical plant maintenance activities will generate pollutants from paint, adhesives, soaps, detergents, solvents, and oils.

Wastewater

Wastewater collected from different facility services and end-users carries a variety of chemical and biological pollutants, several of which are hazardous. Wastewater should be included in a facility's water management and water quality program and should be closely monitored and pretreated prior to its discharge into the public or municipal sewer system. Some developed countries have pretreatment standards and guidelines for health care facilities' wastewater; others apply pretreatment standards established for industrial waste disposal. Developing countries might need to strengthen their capacities for monitoring and controlling health care facilities' wastewater.

Hemodialysis

Hemodialysis is a clinical procedure for patients with chronic renal failure. The procedure partially replaces the kidney function in case of kidney failure by removing bodily fluids and toxins that result from normal metabolic processes. In dialysis, blood is pumped and circulated through an external device called a "hemodialysis unit" (ECRI, 1996) and is kept separated by a semipermeable membrane, from a solution that allows the removal of toxins and excess water from the patient's body fluids without damaging the blood.

The hemodialysis unit consists of three main components: The dialyzer, or semipermeable membrane, that allows the separation of the impurities from the blood; the dialysate system consisting of the solution (solution with electrolyte composition similar to the normal cellular fluid) and an associated circuit for monitoring and controlling the dialysate; and an extracorporeal blood circulation circuit that carries blood from the patient to the dialyzer and back to the patient (ECRI, 1991).

The dialysate, or electrolytic fluid, is customized to correct the body electrolyte disorders of the specific patient. Water is added to the concentrated dialysate to produce the appropriate formula. The preparation of the dialysate requires extremely pure water.

Studies conducted by ECRI (1996, 1999) indicate that patients in hemodialysis therapy are dialyzed an average of three times per week for three to four hours. During this time, the patient is exposed to approximately 360 liters of water per week—more than 25 times the amount of water a person normally ingests. The membrane or filter is the only barrier between the blood and the dialyzer. If the water used in the process has microorganisms or a high mineral content, there is a very high risk to patient's safety and well being.

The Association for the Advancement of Medical Instrumentation (AAMI) has prepared chemical and bacteriological standards and recommended practices for dialysis (AAMI, 1998). The standard includes the "water quality for dialysis" and provides maximum allowable levels of contaminants. In order to obtain the required levels of quality and purity, water must be treated as described in the water treatment and conditioning section.

For example, the maximum level of aluminum allowed in drinking water by the United States Environmental Protection Agency (EPA) is between 0.05 to 0.2 mg/L. By comparison, the maximum level of aluminum in water for hemodialysis, determined by the AAMI, is 0.01 mg/L. Exceeding the specified levels of aluminum in hemodialysis water could harm the patient. Possible adverse effects include anemia, bone disease, encephalopathy, and other neurological disorders. Hemodialysis departments should have a quality control program to closely monitor and control water contaminants. (see Table 115-1.)

Table 115-1 AAMI and EPA maximum levels of contaminants in water (AAMI, 1998; Health Devices, 1999)

<i>AAMI and EPA Maximum Levels of Contaminants Water</i>		
<i>Contaminant</i>	<i>AAMI standard for dialysis water, mg/L</i>	<i>EPA standard for drinking water, mg/L</i>
Aluminum	0.01	0.05 to 0.2
Arsenic	0.005	0.05
Barium	0.1	2.0
Cadmium	0.001	0.005
Calcium	2.0	not regulated
Chloramines	0.1	4.0
Chlorine	0.5	4.0
Chromium	0.014	0.1
Cooper	0.1	1.3
Fluoride	0.2	4.0
Lead	0.005	0.015
Magnesium	4.0	not regulated
Mercury	0.0002	0.002
Nitrate	2.0	10.0
Potassium	8.0	
Selenium	0.09	0.05
Silver	0.005	0.10
Sodium	70.0	not regulated
Sulfate	100	400
Zinc	0.1	5.0

Conclusions

Water systems have profound implications for the performance of health care facilities and the expected outcomes of health care processes and procedures. Facilities should have an adequate management and quality control system for used and discharged water in order to prevent problems for people, equipment, and the environment. From the health perspective, water is one of the main sources of nosocomial infections (Rutala and Weber, 1997) and from the engineering perspective, one of the main causes for equipment deterioration and breakdown.

Water is a strategic energy resource that should be used and managed efficiently. Water waste or improper usage and disposal have a negative environmental impact and an adverse economic effect because of the resource expended in the costly process of treatment and conditioning.

Protection of the environment is an increasing concern worldwide. Governments and society are looking more closely into issues that negatively affect the environment. Usage and disposal of water in health care facilities is one of those issues, especially for developing countries that have but where health care is part of a small industrial sector but is one of the larger consumers of water.

Disaster Planning

Gary H. Harding

Greener Pastures, Inc.
Durango, CO

Alice L. Epstein

CNA HealthPro
Durango, CO

In today's uncertain environment, every organization should have a disaster preparedness or emergency preparedness plan. While recent events such as the attacks on the World Trade Center surely have brought attention to the need for disaster plans in private and public facilities across the country, the health care industry might be slightly ahead of others in preparedness efforts because the involvement of health care providers as a resource and support for handling disasters preceded recent events by centuries.

The U.S. government has required disaster plans in health care facilities since 1967. They have since evolved into Emergency Management Plans, which encompass disaster preparedness, planning, mitigation, and recovery. While the safety officer might have had, and might continue to have, primary responsibility for the plan, certainly much greater emphasis on the part of administrative management and affected departments (e.g., epidemiology, infection control, radiation safety, and emergency medicine) has been mandated by need and regulation. Clinical engineers can, and should, assume primary responsibility for portions of the disaster plan that are directly related to their service and should be prepared to assume back-up responsibility for other related activities. Training and experience to become, and remain, an effective clinical engineer provides a strong base on which to provide support and to assume direct responsibility if the need arises. Lessons learned in facility management theory and operation, critical thinking, logistics, product acquisition, and product support can be applied to many other services if the disaster dictates. Yet, in time of need, we all should remember that clinical engineers might just need to be another pair of hands, a Good Samaritan, or a friendly body willing to listen or act.

The Engineer Professional Advisory Committee of the U.S. Public Health Service decided in 2000 that managers responsible for the organization of the Public Health Service response to disasters and emergencies needed a primer on the capabilities of engineering disciplines to facilitate the inclusion of engineers in emergency situations. The Handbook developed states, "They (engineers) possess strong problem solving and organizational skills. They have the analytical and technical skills to evaluate problems, develop solutions, and bring those solutions to reality . . . While engineers specialize, their capabilities tend to transcend their specialization." (USPHS, 2000).

This handbook identifies (for managers) and promotes the different types of engineering duties and tasks that might be best solved by an engineer. The hope of the authors of the handbook is that every engineer who participates in health care-related emergencies, regardless of specialization, will become familiar with (and preferably certified through) training in the following areas:

- Administrative services
- Information services
- Patient record management
- Communications systems, emergency communication frequencies
- FEMA, NDMS
- Disaster planning
- Medical product logistics
- Hazardous materials management
- Water and waste management treatment systems and testing
- Facility management and utility systems
- Structural integrity

- Emergency level clinical skills, including mandatory cardio-pulmonary resuscitation (CPR) and first aid certification, with emergency medical technician (EMT) certification desirable
- Field management of mass casualties (USPHS, 2000).

By definition, disaster plans can not be all encompassing. Unfortunately, no expert can forecast all types or special nuances of possible disasters, internal or external. The purposes of the overall plan are to identify potential disaster scenarios and to offer contingency responses, while maintaining flexibility to allow professionals to modify or improvise to address any nuances that actually occur. The objectives of the disaster plan should reflect the purpose and goals of the organization. If the organization delivers medical care, examples of objectives could include the following:

- Attending promptly and effectively to all individuals requiring medical attention
- Protect patients, visitors, and staff from injury
- Protect property, facility, and equipment
- Correlating with, and participating in, community disaster plans
- Outlining each department's responsibilities
- Preparing the staff and hospital resources for optimal performance in an emergency
- Satisfying all applicable regulatory requirements

Emergency situations and/or disasters that have a high degree of probability of one or more occurring within the community or the hospital are:

- Fire
- Chemical spill with toxic release—chemical accident
- Major traffic accident
- Multiple casualty incident
- Tornado
- Earthquake
- Blizzard (snow or inclement weather)
- Terrorist activity
- Airport disaster
- Bomb threat
- Industrial accident
- Building or structure collapse
- Riot
- Hostage situation
- Protestors
- Chemical hazards
- Biohazards

The intent of this chapter is to review the responsibilities of clinical engineering in the disaster planning, implementation, and recovery processes. It is not intended to provide a detailed disaster plan. The full disaster plan should be developed in conjunction with all internal and external participants (e.g., regional public entities, utility management services, police, fire, and emergency management). The following sections discuss issues sur-

rounding planning, implementation, and recovery from known disaster types, with the objectives of the health care organization in mind, but specifically focusing on the role of the clinical engineer.

Framework—Emergency Preparedness Regulations and Accreditation Requirements

Governmental Bodies

The basic governmental framework under which disaster planning is expected to occur is being developed as a result of recent events. Creation of a new, cabinet-level agency, the U.S. Department of Homeland Security (DHS), has occurred and is expected to oversee federal involvement “in the event of terrorist attack, national disaster, or other large-scale emergency.” The framework and method of implementation is currently under construction, although it appears that DHS intends to manage efforts centrally, but also to delegate responsibilities to a number of other federal agencies (e.g., the Centers for Disease Control and Prevention, the Office of Emergency Preparedness, and the Federal Emergency Management Agency) and, ultimately, to each state.

Actual federal laws and regulations mandating disaster planning by health care entities are slim. Typically, they are vague and not easily accessed, understood, or particularly enlightening. Title III of the Superfund Amendments and Reauthorization Act of 1976 mandated that every state form local emergency planning committees (LEPCs) and a state emergency response commission. This remains the basic tenet under which the federal government delegates responsibility for disasters to states.

An additional federal requirement for developing and implementing disaster planning in health care facilities is buried within the Medicare Conditions of Participation (at one time, under the auspices of the Health Care Financing Administration (HCFA), now termed the Centers for Medicare & Medicaid Services (CMS)), requiring health care facilities that receive federal Medicare/Medicaid funding to have an emergency preparedness program. CMS surveyors address staff preparation for emergencies and disasters, querying staff as to what they would do in the event of an emergency and evaluating staff responses against what surveyors consider the correct answers. Surveyors question the availability of emergency power and whether staff are aware of the electrical outlets that are powered by emergency power.

DHS offers disaster assistance under The Robert T. Stafford Disaster Relief and Emergency Assistance Act, which historically has been administered by the Federal Emergency Management Agency (FEMA). In the event of an emergency, the governor of a state determines that the features of the disaster are beyond the abilities of the state to handle; the then governor contacts the president to request relief and, if granted, financial, administrative, and other federal resources are made available. However, new changes include multiagency participation such as the CDC’s National Pharmaceutical Stockpile, which ensures “the availability and rapid deployment of life-saving pharmaceuticals, antidotes, other medical supplies and equipment...” While the program suggests that it was developed in response to the September 11, 2001 terrorists attacks the agency states that the stockpile includes those items that are “necessary to counter the effects of nerve agents, biological pathogens, and chemical agents.” A 12-hour “Push Package” is noted as being readily available, although tailored packages, noted as Vendor Managed Inventory (VMI), also can be requested. Unfortunately, the itemization of what is included in the package or able to be requested under the VMI is not provided in an easily accessible format. Accordingly, whether the CDC expects to offer packages for all types of disasters versus just nerve agent, biological, toxin or chemical disasters, and what exactly is available in the way of medical supplies and equipment remains unclear.

Also embedded within the federal government’s agency function is the Department of Health and Human Services (DHHS) Office of Emergency Preparedness (OEP). It is charged with being the lead agency for health and medical response to terrorist activities, natural disasters, transportation disasters, and technological disasters. The OEP directs and manages the National Disaster Medical System (NDMS), a cooperative, asset sharing partnership among DHHS, the Department of Defense, the Department of Veterans Affairs, FEMA, state and local governments, private businesses, and civilian volunteers. The framework under which this agency works, how it is accessed, what it can provide, how it can provide it, and how it is differentiated from other agencies are under construction. Currently, very little useful information related to disaster planning is provided. Directions for participation require contacting their LEPC directly. While the NDMS offerings are somewhat nebulous, health care facilities voluntarily participate by providing bed availability information to a local coordinating center, agreeing to treat NDMS patients, and participating in NDMS exercises.

The Occupational Safety and Health Administration provides regulations for employers, including health care entities. 29 CFR § 1910 requires health care facilities to address certain man-made disasters for the protection of employees. An internal (employee-safety) disaster plan must be developed and must include emergency escape procedures, procedures for employees who must stay to perform critical tasks, and procedures to account for all employees after the emergency.

The Environmental Protection Agency (EPA) under the Emergency Planning and Community Right to Know Act (42 USC §11001) discusses the release of hazardous substances that can cause an emergency. It requires states to establish an emergency response commission and HAZWOPER plan. Hospitals that are designated to receive victims of hazardous substance emergencies must have an emergency response plan, decontamination capabilities, personal protective equipment, and trained employees.

Many state and local agencies that have jurisdiction, (e.g., fire departments) mandate compliance with National Fire Protection Association (NFPA) standards. NFPA 99 (Standard for Health Care Facilities) and NFPA 101 (Life Safety Code) include requirements for an emergency management plan. Within the Life Safety Code, all health care facilities are required to keep written copies of a plan for the protection of all persons in the event of a fire, evacuation to an area of refuge, and to evacuation from the build-

ing when necessary. A copy of the plan must be readily available in the telephone operator’s location or security center. The written plan must include the use of alarms, the transmission of alarms to the fire department, response to alarms, isolation of the fire, evacuation of immediate the area and smoke compartment, and extinguishment of the fire.

Requirements and authority to develop and implement disaster plans, conduct training and exercises, and establish mutual aid agreements can be found in most state department of health regulations, as well as in health care licensing organizations, accreditation standards, and organizational bylaws and policies. Engineers should review state-specific information because it is likely to be more detailed and, thereby, more useful. Following is a synopsis of the standards.

JCAHO

The Joint Commission for Accreditation of Healthcare Organizations (JCAHO) modified its standards in 2001 to include emergency management and community involvement concepts. Organizations were directed to assume an “all hazards” approach to disaster planning, with a responsibility to review, analyze, and address all hazards that are likely to occur and to be a serious threat to the community. While JCAHO has always required preparation for disasters, JCAHO mandated after September 11, 2001, that organizations communicate and coordinate with one another (effective since January 2003).

The JCAHO requirements apply to the full range of hospitals from small rural facilities to academic medical centers in urban locations. The preparedness standards are focused on the following four areas:

1. Emergency preparedness management plan
2. Security management plan
3. Hazardous materials and waste management plan
4. Emergency preparedness drills

JCAHO identifies an emergency as a natural or man-made event that suddenly or significantly disrupts the environment of care or actual care and treatment, as well as changes or increased demands for the organization’s services. Four phases (mitigation, preparedness, response, and recovery) must be addressed. The organization also must participate in two drills annually, preferably community wide.

JCAHO recommends that the plan be general, but also that it provide the flexibility to allow responses specific to disaster type; separate plans for each disaster type are discouraged. Because JCAHO believes that disasters will occur at the local level, they emphasize that organizations might be on their own for 24–72 hours following the disaster. As a result, emergency medical services, fire departments, police, public health agencies, and local leaders must be prepared to respond.

JCAHO standards for the “Emergency Preparedness Management Plan” require hospitals to address the following:

- Specific procedures in response to a variety of disasters or emergencies
- Role in community wide plan
- Role of external authorities
- Space, supplies, security
- Radioactive or chemical isolation & decontamination
- Notifying and assigning personnel
- Evacuation and alternative care site
- Managing patients
- Backup for utilities and communication
- Orientation and education, including emergency procedures in the event of equipment failure
- Performance monitoring
- Annual evaluation

It is important for clinical engineers to address each element as it applies to their department and individual staff members. JCAHO surveyors schedule on-site assessments and will examine how the organization develops, implements, and improves the emergency management plan. They will examine whether a variety of possible events have been identified and addressed and whether staff members understand their roles and responsibilities. A new emphasis on managing the logistics of critical supplies and transportation of equipment critical for the clinical engineer.

Basics of Disaster Planning and Mitigation

Recognizing now that there is a responsibility to “be prepared,” the following sections discuss methods that can be used in planning, and some of the specific hazards that are likely to be encountered. Remember that the discussion does not represent a detailed discussion of these matters and that it must be supplemented by local, state and other resources. There is no single hierarchy for emergency management structure (e.g., committees, terminology, and decision tree) that is applicable to all states, organizations, or situations. Expect the process, participants, methods, and most other aspects of emergency management to vary. However, one basic methodology (Hazard Vulnerability Analysis) does apply under most circumstances.

Hazard Vulnerability Analysis

JCAHO requires accredited health care facilities to assess proactively their vulnerabilities in order to improve disaster readiness. The analysis should be performed annually or amended if there are significant changes that could affect the analysis. The facility

should be using the information gathered from the Hazard Vulnerability Analysis to refine its emergency preparedness plan, based upon logistics specific to the organization. A full vulnerability analysis requires the skills and knowledge of many different professionals. The clinical engineer can contribute to the assessment in collaboration with, among others, structural engineers, radiation specialists, plumbers, and electricians.

The Pan American Health Organization (PAHO), a regional office of the World Health Organization (WHO), offers an authoritative disaster mitigation book that includes algorithms to conduct hazard vulnerability analyses and to determine priorities (PAHO, 2000). Vulnerabilities are separated into the following categories: Structural, medical and support equipment and installations, and administrative and organizational. Vulnerability assessments can be used to improve disaster preparedness. WHO stresses the importance of disaster mitigation through the adoption of preventive measures.

Assessing the hazards and vulnerability of the organization first requires calculating the probability that a disaster will occur. Factors to consider in assessing probability include impact of geography, proximity to hazardous industries, disaster history, warning systems, and social or political unrest. Following an assessment of disaster probability, the team should estimate the potential damage, loss, and harm that could result. While there are a myriad of potential negative impacts, primary categories of damage include human, structural/property, loss of mechanical and electrical systems, financial, and operational.

Structural assessment begins with a visual inspection of the facilities. (While not a part of the analysis, mitigation could start immediately by repairing existing structural problems and deficiencies that are noted.) Assessment of the vulnerabilities of medical and support equipment and installations is an area in which clinical engineering contribute significantly. Are there sufficient medical devices on hand and adequate if evacuation becomes necessary? For example, will fixed equipment stand the stress of an earthquake? Can existing critical life support equipment function or are there medical alternatives readily available in the event of power loss or evacuation? Financial vulnerability includes the cost of lost business, the cost of providing emergency services, cash reserves on hand for the purchase of emergency supplies, and adequate insurance. Operational vulnerability includes the loss of essential personnel, management survivability, and crisis/media management.

Recognized areas of vulnerability of importance to the clinical engineer include the following.

Electricity

Specific to essential or critical life support equipment in areas such as nursing, pharmacy, blood bank, central suction, central sterile supply, surgical suite, labor/delivery, intensive care units, nursery, cardiac catheterization laboratory, emergency department, radiology, treatment and patient bed space

Emergency Generator

Emergency outlet identification and testing, length of backup electrical power duration, limitations on fuel availability and delivery, service to piped medical gas alarms, cardiology alarms, dedicated lines to emergency department (ED), operating room (OR), obstetrical suite (OB), and intensive care unit (ICU), blood storage, central vacuum systems, medical air compressors, and availability of extension cords

Water Supplies

Vacuum systems (if connected to water), sterilization, parental systems, radiology film development equipment, dialysis, portable suction options

Gas systems

Availability of portable cylinders, gas shutoff, alarms for medical gas supplies, alarms for accidental release of ethylene oxide and other hazardous gases, loss of piped oxygen due to bulk supply failure, automatic transfer to reserve oxygen supply system, low pressure alarm signal

Communications

Wire operated, radio wave operated (e.g. radios, pagers, televisions, telemetry, cellular phones, handheld PCs) availability of batteries for all systems, availability of PC not on hospital network, public address systems

Medical Devices

In addition to a current inventory of equipment in use, the clinical engineer also should know the levels of equipment that are stockpiled and ready for use in the event of an emergency. Are there alternative means to provide the necessary clinical equipment or support and/or how many days would it take to acquire same? Critical equipment includes but is not limited to:

- Anesthesia equipment
- Autoclave/sterilizers
- Blood bank freezers
- Cardiology/respiratory monitors
- CT scanners
- Defibrillators
- Dialysis equipment
- EEG monitors
- EtO sterilizers
- Infant incubators

- Infusion pumps and controllers
- Laboratory equipment
- Laparoscopy equipment
- Laryngoscopes with extra batteries
- Manual resuscitators
- MRI
- OR tables
- Orthopedic instruments, such as hand-powered drills and saws
- Oxygen concentrators
- Plate developers and processors
- Portable oxygen
- Pulmonary function analyzer
- Pulse oximeters
- Respirators
- Sterilizers
- Suction machine/pump
- Traction equipment
- Ultrasound equipment
- Ventilators (adult and pediatric)
- X-ray equipment

Algorithms are not the only process to assess vulnerability. Organizations, including the American Hospital Association, suggest questions to measure vulnerability. Following are some questions that could be asked:

What could go wrong that is under the domain of your department?

- Is there anything (e.g., equipment and service) under your domain that could trigger or contribute to a disaster?
- If utilities failed, how would the failure interrupt services for which you are responsible? Will utility service failure trigger backup power? Has the emergency power/utility crossover been tested for each piece of life-support equipment?
- If demand for equipment and service requests increases, is there a plan for acquiring increased equipment and parts that identifies sources and capacity?
- In the event of a large-scale disaster, is there a method and decision algorithm for allocating and/or re-allocating scarce critical equipment (e.g., ventilators)?
- If supplies and parts did not arrive when needed, how would clinical engineering cope?
- Where are backup and replacement equipment to come from? Who is responsible for arranging and triggering delivery?
- Are internal systems in place to notify suppliers of an emergency situation? Have the mechanics of delivery been worked out for the duration of the disaster?
- Are there backup supplies identified for critical equipment and components?

Hundreds of additional questions could be asked. Part of the plan development process certainly includes all involved parties examining their own departments/functions with respect to intra- and interdepartmental issues that might arise. Asking and answering these questions can improve the actual response in the event of disaster.

Departmental response is important to plan and understand. Chain of command and delineation of span of control are as important at the department level as they are in top management. It is important that all department members understand the role of clinical engineering during a disaster, as well as their specific responsibilities and that these may change as needs of the crisis vary. Management should keep a current roster of clinical engineering emergency contact telephone numbers. A contact plan should be developed and detailed in the disaster plan.

Clinical engineering should be responsible for development of their section of the disaster plan. Often departments develop their own disaster plans under the umbrella of the facility plan, with standard operating procedures specific to clinical engineering. It is imperative that the department-specific plans are not developed outside the umbrella and oversight of the complete plan. It is important, for example, that other departments (e.g., nursing and respiratory therapy) understand and have in writing the conditions under which they should contact clinical engineering. Specific examples can help individuals within those other departments to respond more appropriately and effectively to disasters. As a result, clinical engineering should contribute to the development of such departmental plans, policies, and procedures.

Similarly, other departments that have information or a possible impact on clinical engineering should participate in the development of the clinical engineering departmental plan. One of the most important relationships that clinical engineering should forge as part of the disaster plan is with facilities engineering. There are so many cross-over issues and combined knowledge bases between these two departments that a close relationship, understanding of function and interaction, and methods of cooperation are essential.

It is imperative that the clinical engineering contribution to each aspect of the plan be reviewed, understood, and approved by all parties affected by the plan. It should be understood that this contribution includes the disaster planning, implementation, and recovery processes.

Following are discussions relating to specific disasters, issues, and clinical engineering.

Fire

Clinical engineering does not typically bear primary responsibility for fire response. However, there are specific aspects of fires that could involve clinical engineering. For example in an internal disaster, equipment under the clinical engineer's control could have been the cause of the fire or could become involved as the fire propagates. Similarly, a fire could require the evacuation of parts or all of the facility and the ability to continue providing critical support during and subsequent to evacuation. Maintaining an awareness of equipment that poses a recognized risk of fire, steps that can minimize the likelihood, and procedures to follow in the event of an equipment-related fire should be developed. The role of clinical engineering in the event of a fire and evacuation should be determined, including: Whether evacuation of a critical care unit is required; the location, availability,

and provision of battery-operated equipment, e.g., transport incubators, or alternative manual modes of support with related equipment, e.g., manual resuscitators, should be identified. It will not suffice for the clinical department's disaster plan to specify, for example, a switch to manual resuscitators if, in fact, those resuscitators are not readily available under a known protocol.

Natural Disasters—Earthquakes, Tornadoes, Hurricanes, Typhoons

Some natural disasters offer the opportunity for early initiation of the disaster plan. For example, hurricanes typically must develop over time, and authorities can provide warning levels accordingly. Some, like earthquakes, occur without warning. While our experience in the U.S. with natural disasters has been characterized by significant property damage, but limited casualties, mass casualties are a distinct possibility. In 2000, the American Hospital Association, with the support of the Office of Emergency Preparedness, issued *Hospital Preparedness for Mass Casualties*. Along with some review and background information, this work provides recommendations for community-wide preparedness, staffing, communications and public policy. It also provides an appendix: "Suggested Issues for Hospital Mass Casualty Preparedness" that includes over five pages of listed issues to be considered. These issues could be operational (e.g., coordination of volunteers); equipment-related (e.g., stockpiling of supplies); problematic (e.g., a weak relationship between hospital and health department); or financial (e.g., a hospital bearing costs of preparedness for events that originate outside its campus). A number of these issues (e.g., stockpiling of equipment) could directly involve clinical engineering.

Man-Made Disaster of Terrorism

Man's inhumanity to man has affected the United States in the Oklahoma City, New York City, and Pentagon disasters. Much has been learned from the emergency management experience surrounding these disasters. From a health care perspective, most of the lessons learned revolve around mass casualties, but as the sophistication and resources of terrorism increase, it seems only a matter of time before disasters related to the release of chemical, biological, or other agents or weapons of mass destruction may follow. Much work is currently being undertaken in planning for these types of disasters, but in 1999 the Association for Professionals in Infection Control and Epidemiology (APIC) and the CDC completed *Bioterrorism Readiness Plan: A Template for Healthcare Facilities*. This document provides an overview of activities relating to:

Reporting requirements and contact information

- Potential agents
- Detection of outbreaks
- Infection control practices for patient management
- Post-exposure management
- Laboratory support and confirmation
- Patient, visitor, and public information

Some of these activities (e.g., transport of patients with communicable disease) certainly can impact on clinical engineering. Examples include the need for equipment decontamination or the use of equipment within cohorted patient populations who present with similar symptoms.

The document also singles out and discusses anthrax, botulism, plague and smallpox. Description of the agent/syndrome; preventive measures; infection control practices for patient management; post-exposure management; laboratory support and confirmation; and patient, visitor, and public information for each is provided. References and resources (e.g., state-specific telephone and other contact information for the FBI and public health directors) are included.

Certainly, there are a great number of other types of disasters (e.g., chemical spills with toxic releases, major traffic accidents, airport disasters, industrial accidents, building or structural collapses, and riots) that must be identified and addressed individually during plan development. References specific to each of them should be identified and considered at that time.

Loss of Communication

Disaster can result in loss of communication within a health care facility. In such an event, external paging systems and cellular telephones can provide an alternative means of communication inside and outside of the facility. While many facilities have strict criteria to eliminate the use of cellular telephones within the structure, it can be essential to set aside this restriction in the event of a disaster that results in loss of conventional communication. If cellular telephone use must be approved (and, in fact, encouraged), potential users also should be counseled to maintain a distance of at least 1 meter from medical equipment. Disaster plans could specify locations in which there is little or no concern for cellular telephone use and interference. Other stand-alone products (e.g., two-way walkie-talkies) typically require greater distances (6–8 meters, or 20–25 feet) from instrumentation for safe use. Specific examples of devices that have been adversely affected by cellular telephone use include cardiac pacemakers (e.g., reversion to default mode) and ventilators (e.g., device shut-off). However, operation of cellular telephones in close proximity (i.e., under 1 meter) to most medical devices (e.g., monitors and infusion control devices) should be avoided because there remains the possibility of such events as parameter changes and alarm adjustment.

Biological and Chemical Contamination of Equipment

If equipment requires decontamination, it is imperative that strict protocols be followed. Check manufacturers' requirements and work with your infection control practitioner and radiation safety officer to develop protocols specific to the equipment.

When possible, noncritical patient care equipment should be dedicated to a single patient (or cohort of patients exposed to the same agent). If shared use of items is unavoidable on noncohort patients, all potentially contaminated, reusable equipment should be appropriately cleaned and reprocessed before use. Policies should be in place and monitored for compliance. Equipment and supplies contaminated with blood, body fluids, secretions, or excretions should be handled in accordance with Universal Precautions, the blood-borne pathogens standard, and handling protocols specific to the agent, to prevent staff or bystander exposures to skin and mucous membranes, contamination of clothing, and transfer of agents to staff, other patients, and other persons.

What Should the Clinical Engineer Do in the Event of a Disaster?

The primary responsibility of the clinical engineer in the event of a disaster is to implement the features of the plan that is specific to the department and the disaster. With no plan, or a poorly conceived or poorly understood plan, one can expect chaos. If the plan has been carefully thought out, contributions to mitigate the disaster will be apparent. Notifying emergency contacts, acquiring an up-to-the-minute inventory and location list, and ensuring function of critical life-support equipment will fall into place naturally. Clinical engineers should expect greater demand on staff and resources. Troubleshooting and problem solving are likely to be the watchwords, with flexibility to respond to the situation paramount.

Being prepared, to the extent practicable, to anticipate need, the potential problems that may result, and alternative methods to address both, can help to make the process of disaster mitigation more successful. Anticipating the need for evacuation and challenges to equipment and medical support can help avert situations in which no reasonable alternative is available or in which the impact of the need is underestimated. Clinical engineers can be a powerful resource, especially if they choose to receive other training in disaster-related services (e.g., CPR, disaster volunteering, or biohazard and chemical hazard response).

Recovery

Recovery is a major part of addressing a disaster. It involves addressing issues remaining after the disaster has been mitigated. The cost for services and replacement of structures that might occur during recovery often involve FEMA and the identification of a disaster area by the president. As noted previously, the governor of the state(s) in which the disaster(s) occur must request the assistance on behalf of those who have suffered as a result of the disaster, according to the requirements of the Stafford Act.

Private reimbursement for loss may be available through insurers. Insurance policies must have been in place prior to the disaster and must cover appropriate exposures (e.g., property, flood, business interruption, earthquake, terrorism/acts of war, equipment replacement, and equipment rental expenses) in order for many of the financial ramifications of disaster to be addressed. Assuming that the insurance purchasing authority for the organization has properly secured insurance, it is important to have up-to-date equipment inventories with replacement values assigned to each piece of equipment. Inventories including photographs of all fixed and possibly expensive equipment) should note the age of the equipment and the expected life cycle. A master log and tracking system for all equipment that leaves the building during a disaster with patients and staff should be maintained. Locating displaced equipment can be almost impossible without a tracking system. Accurately record all expenses. This information will be necessary in order to secure insurance, FEMA, and state reimbursement.

Recovery assessment should be performed as soon as possible after the event. The first assessment should be a safety assessment of the structural integrity of the buildings. Clinical engineering should complete an inventory of all medical equipment for damage assessments. Take pictures of all equipment prior to cleanup. Decisions will need to be made regarding the repair of equipment. Identify the condition of existing equipment and develop a strategy for replacement/repair of equipment, what can be repaired cost effectively, and who should be performing the repair. Evaluate the cost and requirements of in-house versus contracted repair services. Track the repairs, cost, and time expended. Evaluate the effects of sudden power loss when bringing equipment back online. All settings and alarms must be tested before patient use. Document decisions to repair or discard equipment.

The engineering department should be debriefed as a team on the status of the facilities equipment, the staff's contribution to the disaster efforts, and next steps. In order to capture information about how effective staff activities were during the disaster, it is important to document the disaster-related activities of the department staff. A secondary benefit from this process might be that equipment that has not been located might be captured in staff activity documents. Ask the team to identify efforts of disaster assistance that could benefit from changes or improvement. Identify what worked well.

Richter (2003) identifies a number of common postdisaster problems that can occur. Some of the following can impact on clinical engineers:

- Failure of water pressure
- Failure of backflow protection systems
- Failure of emergency generators, air conditioning, and public utility systems
- Difficulties with special needs patients (e.g., ventilator, dialysis)
- Detrimental effect on operating systems (e.g., technology availability) due to volume of patients, evacuees, and residents

- Failure of telecommunications systems/staffing systems
- Flooding of mechanical rooms, (e.g., patient floors, elevator shafts)
- Waste management problems
- Loss of equipment on, and damage to, hospital roofs
- Obstruction from debris
- Inability to secure electronic doors and alarm systems manually

Conclusion

Disasters are no longer events that occur to others. They are far more diversified from the standard flood, earthquake, and natural disasters of the past. In the recent past, development of disaster plans might have been viewed as necessary to comply with federal, local, and licensing authority regulations, but recent man-made disasters have shown all of us that these events can occur anywhere and at any time. Thoroughly and thoughtfully addressing planning, mitigation, and recovery issues on a comprehensive, detailed basis can save lives.

Clinical engineers can expect disasters to place great demands on staff and resources. Reliance on simpler, alternative means of therapy and support can be necessary in some cases. Activating federal, state, and local support channels as rapidly as possible (and consistent with the needs of the disaster) will be important. Special challenges might need to be faced, and perhaps hard decisions will need to be made. Emergency management plans can be a useful base from which to operate and make decisions as long as the plan has been properly thought out and staff understand and follow to the extent that practicable protocols are defined within the plan.

Fortunately, clinical engineers have a strong academic and experiential base on which to participate in disaster planning, mitigation and recovery, as well as direct portions of it. Success depends on the willingness of the clinical engineer to not only offer suggestions, but also to receive them—both offered and received in a constructive, open forum for the benefit of those who could suffer in a disaster. While preplanning and a strong sense and knowledge of responsibility are important during a disaster, it is important to remember that all of us just might need to be an extra set of hands, a willing listener, or prepared to assume primary responsibility for a task not typically within our purview, but necessitated by events.

Section XI

Medical Device Standards, Regulations, and the Law

David A. Simmons

Health Care Engineering, Inc.
Glen Allen, VA

The health care community in general and clinical engineering community in particular face a daunting challenge in the form of countless laws, statutes, regulations, standards, and guidelines. Our qualified and experienced contributing authors provide a robust examination of the many types of laws, regulations, standards, and guidelines, both national and international. It is important to begin by differentiating between the several categories of documents. Laws can be national (federal), state, or local, as in city or town. In these situations, laws are in effect and must be complied with throughout the governing area, e.g., nation, state, or local municipality. While there are no international laws regarding medical devices, there are international standards in place that pertain to the control and service of medical devices. One such standard is ISO 9001:2000, containing the first health care quality management system standard, IWA1. However, standards do not have the effects of laws, since they become compliance documents only when “an authority having jurisdiction” requires compliance. One example would be when a city requires compliance with one or more of the National Fire Protection Association (NFPA) standards.

The first chapter is a primer for understanding the differences between standards, regulations, and laws, as well as the need for standards and the standards development process. It addresses conformity assessment for national and international standards. The next chapter, “Regulation and Technology Assessment Agencies,” provides insight into 43,000 mandatory and voluntary applicable standards, clinical guidelines, laws, and regulations promulgated by more than 1400 organizations and 300 state and federal agencies. It provides a comprehensive list of agencies and organizations that have the most significant clinical engineering and technology involvement. Also included is a list of worldwide technology assessment organizations. The chapter, “Hospital Facilities Safety Standards,” discusses the roles of several organizations that promulgate standards for hospital facilities. These include the Centers for Medicare and Medicaid Services (CMS), formerly Health Care Finance Administration (HCFA), Occupational Safety and Health Administration (OSHA), National Fire Protection Association (NFPA), and Joint Commission on Accreditation of Healthcare Organizations (JCAHO). This is a comprehensive comparison of organizations and standards. JCAHO and its hospital-accreditation program, described in the next chapter, provide essential information for the clinical engineers to understand their roles with respect to accreditation. Following that, the chapter “Medical Equipment Management Program and ANSI/AAMI EQ56,” details the devel-

opment and the substance of a recommended practice document, ANSI/AAMI EQ56, entitled, “Recommended Practice for a Medical Equipment Management Program.” This standard is the culmination of a collaborative effort of JCAHO, the American National Standards Institute (ANSI), and the Association for the Advancement of Medical Instrumentation (AAMI). The EQ56 recommends a program that addresses all aspects of a medical device’s life cycle, from device selection to retirement within a health care organization. Both EQ56 and ISO 9000, discussed in a previous chapter, allow each organization to develop its own program. Both documents embody similar philosophies: EQ56’s is “Say what you do, and then do what you say,” and ISO 9000’s is “Say what you do, do what you say, prove it, improve it.”

The authors of the chapter “Clinical Engineering Standards for Canada,” compare the Canadian Council on Health Services Accreditation (CCHSA) to its United States counterpart, JCAHO. They provide a detailed analysis of the standards development process in Canada, including a section on the elements of the Canadian standard. Peer review is also discussed at length and is worth considering in the United States and elsewhere. “Regulations and the Law” deals with risk management and the regulation of medical devices. Stages of regulatory controls are addressed. The chapter entitled “The EU Medical Device Directives and Vigilance System” describes three primary areas, or directives, for the European Community. These are active implantable medical devices, medical devices, and *in vitro* diagnostics. The directives focus on the essential requirements that constitute the fundamentals of compliance. The description of the two European standards bodies, CENELEC and CEN, leads into a discussion of the harmonization of standards and the European Vigilance System.

The chapter “United States Food and Drug Administration” is a comprehensive and detailed look at the FDA. This is required reading for any clinical engineer to understand the impact and importance of the FDA involvement with medical devices. It is one of the most comprehensive documents regarding FDA activities that this author has seen. Finally, the chapter “Tort Liability for Clinical Engineers and Device Manufacturers” is a must for clinical engineers and manufacturers. The chapter addresses preparation for JCAHO surveys and changes in an organization’s culture. The material also addresses continuous quality-improvement programs and operating-cost reductions, as well as my personal favorite, eliminating the triennial ramp-up for JCAHO surveys.

117

Primer on Standards and Regulations

Michael Cheng

Health Technology Management
Ottawa, Ontario, Canada

The work of clinical engineers has a direct effect on health, safety and the environment. These public health domains are heavily guided by standards and regulations. This chapter provides a brief overview of standards and regulations with special reference to medical devices. Terms such as standards and regulations often are used loosely. More formal meanings of these terms or understandings from current usage among regulatory professionals are given here. One should keep in mind that the fields of standards, in general, and regulations of medical devices, in particular, are evolving rapidly. This chapter provides a frame of reference for other chapters in this section of the handbook on Standards, Regulations and the Law. Pointers will be made where a term or topic introduced is described in other chapters. In other chapters in this handbook, regulations and the law; regulating medical devices; the Global Harmonization Task Force (see Chapter 124), and post-market surveillance and vigilance on medical devices (see Chapter 139) will be discussed. A general understanding of the different aspects of standards is presented followed by reference to biomedical standards and the importance of clinical engineering participation in standards development.

Standards Defined

Various technical definitions of standards exist, but it would be difficult to find one that can satisfy all applications of the term. Following are three meanings for “standard” taken from the *Webster’s International Dictionary*, and a fourth definition from the International Standardization Organization (ISO):

1. Something that is established by authority, custom, or general consent as a model or example to be followed;
2. A definite level or degree of quality that is proper and adequate for a specific purpose;
3. Something that is set up and established by authority as a rule for the measure of quantity, weight, extent, value, or quality; and
4. Documented agreements containing technical specifications or other precise criteria to be used consistently as rules, guidelines, or definitions of characteristics, to ensure that materials, products, processes, and services are fit for their purpose.

Standards can establish a wide range of specifications for products, processes, and services.

- Prescriptive specifications obligate product characteristics; for example, device dimensions, biomaterials, test or calibration procedures as well as definitions of terms and terminologies.
- Design specifications set out the specific design or technical characteristics of a product, for example, operating room facilities or medical gas systems.
- Performance specifications ensure that a product meets a prescribed test; for example, strength requirements, measurement accuracy, battery capacity, or maximum defibrillator energy.
- Management specifications set out requirements for the processes and procedures companies put in place, such as for quality systems for manufacturing or environmental management systems.

A standard might contain a combination of specifications. Performance, prescriptive, and design specifications have existed for many years. Management specifications, however, are rapidly gaining prominence.

Recent years have seen the development and application of what are known as “generic management system standards,” where “generic” means that the standards’ requirements can be applied to any organization, regardless of the product it makes (or whether the “product” is actually a service activity), and “management system” refers to what the organization does to manage its processes. Two of the most widely known series of international standards falling into this category are the ISO 9000 series (see Chapter 119) for managing quality systems, and the ISO 14000 series for environmental management systems. Wide-ranging information and assistance relating to these standards and their application is available on the web site www.ISO.org. The ISO quality systems standards for

medical device manufacturing are the ISO13485 in conjunction with ISO9001 and ISO13488 in conjunction with ISO9002.

One might hear terms such as “outcome-oriented standards,” “objectives standards,” “function-focused standards,” and “results-oriented standards.” Essentially, these terms indicate that the standards specify the objectives, or “ends,” to be achieved, while leaving the methods, or “means,” to the implementers. This can minimize possible constrictive effects of standards (see Limitation of Standards below). One management standard for medical equipment is the ANSI/AAMI EQ56 described by Ethan Hertz (see Chapter 122), which also uses a results-oriented approach.

Need for Standards

Standards can serve the following different purposes:

- Providing specifications or other criteria that a product, process, or service must meet.
- Providing information that enhances safety, reliability, and performance of the products, processes, and services.
- Assuring consumers about reliability or other characteristics of goods or services provided in the marketplace.
- Giving consumers more choice by allowing one firm’s products to be substituted for, or combined with, those of another.

Although one often takes for granted the advantage of being able to order shoes or clothes simply by referring to a size, this is only possible because manufacturers follow some industrial standards in making shoes and clothes. In contrast, incompatibility between electrical plugs and receptacles is a prime example of different countries not following the same standard. When North Americans want to use a portable computer or other electrical appliance in Europe or Asia, they find that the plug and voltage are not compatible, and this can be a frustrating experience. Clinical engineers are well aware of incompatible consumables or replacement parts in medical devices of similar function, made by different manufacturers. The lack of standard consumables and repair parts is an important cause of medical equipment problems in developing countries.

With the world becoming a global village, the need for, and benefits of, standardization are becoming more and more important internationally for manufacturing, trade, and communications. Quality systems and other management standards can provide common references to the kind of process, services, or management practice expected. Global communication will be difficult without international standardization. The Internet functions because of globally agreed-upon interconnection protocols, for example

Most medical devices, like drugs, are health care products made available globally through trade or international co-operation. The safety, effectiveness, and consistent quality of medical devices are now international public health issues. Therefore, global standardization of medical device standards and regulations has become increasingly important.

Standards Vs. Regulations

Most standards are voluntary. However, a standard may be mandated by a company, a professional society, an industry, or a government. A standard may be called a “regulation” when it is mandatory. The mandate might or might not be legally based.

When a standard is mandated by a government, it normally becomes legally obligatory based on regulations or a law established by the government. Governments in Canada, the European Union, and the United States have recently established policies to recognize hundreds of voluntary standards that are applicable to medical device regulations. These standards, however, are not mandatory. Manufacturers can choose between conformance with the recognized standards or other means to demonstrate product compliance with regulatory requirements.

Standards Development Process

A standard can be set and mandated by an authority. The current trend, however, is to adopt standards established by consensus from all interested parties (the stakeholders). In general, to be accepted voluntarily, standards should have the following attributes:

- Their development should be overseen by a recognized body to ensure that the process is transparent and not dominated by undue interests.
- The development process should be open to input from all interested parties and the resulting document should be based on consensus. Consensus, in a practical sense, means that substantial agreement is reached by interested parties involved in the preparation of a standard. This includes steps taken to resolve all objections and implies much more than the concept of a simple majority, but not necessarily unanimity.
- Good technical standards should be based on the consolidated results in science; and technology and experience and aimed at the promotion of optimum community benefits.
- Standards should not hinder innovations and should be reviewed periodically to remain updated with technological advances.

For many standards development organizations, the designation of the term “standard” to a document requires specific conditions. Figure 117-1 shows the twelve steps taken by credible standards development organizations in developing and maintaining a standard.

This formal process, particularly the consensus steps 4, 5 and 6, is the norm for the resulting document to be recognized as a standard. There are many types of “standard-like” documents from standard organizations, but the documents may not have wide acceptance as standards because their development procedures did not satisfy the above norm. For example, technical specification (TS) and technical report (TR) from ISO and Technical Information Report (TIR) from the Association for the Advancement of Medical Instrumentation (AAMI) are standards-like documents. The reader should refer to the definitions for such types of documents given by the parent organizations.

Conformity Assessment with Standards

The four common industrial methods for assessing conformity to a standard are listed below:

1. A product’s conformity to standards is commonly assessed by direct testing.
2. A process can be assessed by audit. Certification organizations or regulatory authorities attest that products or processes conform to a standard by authorizing the display of their certification mark.

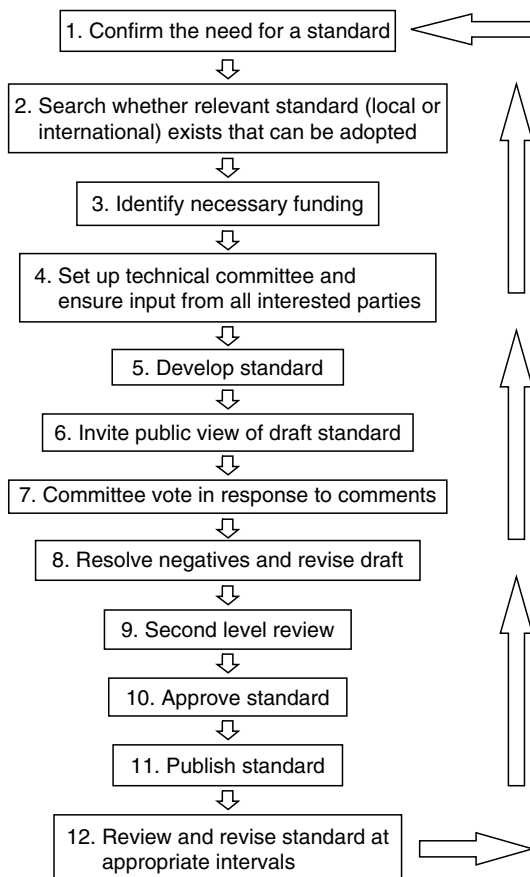

Figure 117-1 Twelve steps in standards development and maintenance.

3. The conformity to a management standard by an organization is known as “management systems registration,” a relatively new term used primarily in North America. Formally established audit procedures are followed by certified auditors who are supported by technical experts of the domain under audit. Management system registration bodies (registrars) issue registration certificates to companies that meet a management standard such as the ISO9000 family, or to medical device manufacturers that meet the ISO13485/ISO9001 standards. Note that in North America, the term “registration” is used for an organization, while “certification” is reserved for products. Many other countries use “certification” for both a product and an organization.
4. Accreditation is used in Canada and the United States for affirming that a health care organization meets requirements set by a service standard. Usually, the health care facility is visited and reviewed by a team of appointed peers. Accreditation is also used by national authorities to recognize third-party assessment agencies and standards-development and auditor-training organizations.

National and International Standards Systems

A country might have many voluntary standards bodies. However, normally there is one official national organization that coordinates and accredits the standards-development bodies in that country. This official national organization would have the authority to endorse a document as a national standard in accordance with official criteria, and it also represents the country in the international standards organizations. In the United States, the American National Standards Institute (ANSI), a non-profit organization, is such an organization. In Canada, it is the Standards Council of Canada (SCC), a crown (i.e., government) organization. In Europe, it is a committee composed of Comité Européen de Normalisation (CEN), the European Committee for Electrotechnical Standardization (CENELEC) and the European Telecommunication Standards Institute (ETSI) that regroups the different previous European national standards bodies.

Three major international standardization organizations are the International Organization for Standardization (ISO), the International Electrotechnical Commission (IEC), and the International Telecommunication Union (ITU). Generally, ITU covers telecommunications, IEC covers electrical and electronic engineering, and ISO covers the rest. The work in information technology, risk management, quality systems, and many other areas carried out by a joint ISO/IEC technical committee.

There are other organizations that produce documents on international standardization. Their documents are usually adopted by ISO/IEC/ITU as international standards if those documents were developed in accordance with international consensus criteria. Any group of five member countries can propose a standard to the ISO for adoption as an international standard. Contact with these organizations can be made through the following websites: www.ISO.ch, www.IEC.ch, and www.itu.int/home/index.html. These web sites link to global standards.

Identification of Standards

Standards are generally designated by an alphabetical prefix and a number. The acronyms (e.g., ISO, IEC, ANSI, CAN, EN, and DIN) indicate the standard body that has approved them. The numbers identify the specific standard and the year in which it was finalized. The standards reference number quite frequently gives an indication of adoption where standards are equivalent. For example:

- CAN/CSA-Z386-94 refers to a standard developed in 1994 by the Canadian Standards Association (CSA), one of four accredited Canadian standards development organizations, and designated by the Standards Council of Canada (SCC) as a Canadian national standard.
- ANSI/AAMI/ISO 15223:2000 refers to the international standard ISO 15223 (established in 2000) adopted by AAMI, which in turn is designated by ANSI as an American national standard.
- UNI EN ISO 9001 indicates an Italian national standard (UNI) that is an adoption of a European standard (EN), which is an adoption of the International Standard, ISO9001.

Limitation of Standards

One major limitation is that standards are based mainly on retrospective experience, and this may inhibit innovation or limit progress. Furthermore, standards can cover only a limited scope at the time of development, and they could be inappropriate for unforeseen situations. Therefore, it is important to know the origin and background of the standards to be used. Table 117-1 presents a checklist in using a standard.

Another possible problem associated with standardization is that participation in the development of standards requires funding and time, which many individuals, small businesses, or organizations cannot afford. Therefore, standards development can fall under the strong influence of those who can afford the cost and time to participate (e.g., big businesses).

References for Biomedical Standards

Hundreds of biomedical standards exist, and the reader can identify most of them through relevant web sites. The richest source is ISO: www.ISO.ch. For American national standards, refer to www.ANSI.org, and for Canadian national standards, www.SCC.ca. For other national standards, non-national standards, or standard-like documents on medical devices, refer to the extensive sources provided by Bruley and Coates (Chapter 118). “The Guide to Biomedical Standards” by Aspen Publications, which has been published for two

decades, lists standards that concern medical devices and facilities throughout the world. While it is a handy hard copy reference, one must check the Web for the latest standards.

Increasingly, regulatory authorities recognize voluntary standards. Standards that are recognized by the United States Food and Drug Administration Center for Devices and Radiological Health (FDA CDRH) (see Chapter 126), www.fda.gov/cdrh/modact/fr0225ap.pdf, and those by Health Canada can be found at www.hc-sc.gc.ca/hpb-dgps/therapeut/htmleng/policy.html.

Conformity to such standards can serve as evidence in meeting certain regulatory requirements by the corresponding authorities.

Standards and the Clinical Engineer

As a professional user of standards, the clinical engineer should be aware of the limitations of standards (Table 117-1). A standard is a useful reference in decision making, but it should never replace professional judgment and responsible decision making.

Participation in Standards Development

Not so long ago, standardization was a field reserved for only a few specialists. Today, standardization has emerged as a major technical and commercial element. Clinical engineers must play an active role in standards development or be prepared to accept standardization that is established without them or without consideration of their interests. As a professional user of medical devices and manager of health care services, the clinical engineer makes important contributions in developing standards that govern medical devices and the health care environment.

Participation in standards development can be made directly by becoming involved with technical committees. Some standards development organizations will fund an expert's attendance at their technical committees. The clinical engineer also may seek funding from his or her employer or professional societies. Input can be made during the

Why should it be used?

public consultation phase of the standards development process. (See step 6 in the standards development process (Figure 117-1).) The Internet has made such public access and input to documents convenient.

Standards development organizations normally are covered by insurance, which in turn should cover individual committee members. Those who are concerned about legal liability can make enquiries to the organization before participation.

Medical Device Regulatory and Technology Assessment Agencies

Mark E. Bruley

Vice President, Accident and Forensic Investigation ECRI,
Plymouth Meeting, PA

Vivian H. Coates

Vice President, Technology Assessment and Information
Service, ECRI
Plymouth Meeting, PA

To be effective, clinical engineering department management and development requires a basic knowledge of relevant regulatory and technology assessment agencies. Regulatory agencies set standards of device performance, problem reporting, and recordkeeping for the clinical departments and technologies for which they are responsible. Furthermore, in the ever-expanding role of the clinical engineer in the technology decision making processes of hospital administration, the engineer must be aware of the technology assessment agencies that are valuable information resources in the rapidly developing, market-driven health care technology arena.

This chapter presents an overview of regulatory and technology assessment agencies in the United States, Canada, Europe, and Australia that are germane to clinical engineering. Because of the extremely large number of such agencies and information resources, this chapter focuses only on those of greatest relevance and/or informational value. The reader is directed to the references and sources of further information presented at the end of the chapter.

Regulatory Agencies

Within the health care field, there are over 43,000 applicable standards, clinical practice guidelines, laws, and regulations (ECRI, 2001). Voluntary standards are promulgated by more than 1,400 organizations; mandatory standards by more than 300 state and federal agencies. Many of these organizations and agencies issue guidelines that are relevant to the vast range of health care technologies within the responsibility of clinical engineering departments. Although many of these agencies also regulate the manufacture and clinical use of health care technology, such regulations are not directly germane to the management of a clinical department and are not presented.

For the clinical engineer, many agencies promulgate regulations and standards in areas including electrical safety, fire safety, technology management, occupational safety, radiology and nuclear medicine, clinical laboratories, infection control, anesthesia and respiratory equipment, power distribution, and medical-gas systems. In the U.S., medical device-

problem reporting is also regulated by many state agencies and by the U.S. Food and Drug Administration (FDA) via its MEDWATCH program. It is important to note that, at present, the only direct regulatory authority that the FDA has over U.S. hospitals is in the reporting of medical device related accidents that result in serious injury or death. Other chapters in this section discuss in detail many of the specific agency citations. Presented below are the names and addresses of the primary agencies whose codes, standards, and regulations have the most direct bearing on clinical engineering and technology management.

Technology Assessment Agencies

Technology assessment is the practical process of determining the value of a new or emerging technology in and of itself or against existing or competing technologies, using safety, efficacy, effectiveness, outcome, risk management, strategic, financial, and competitive criteria. Technology assessment also considers ethics and law as well as health priorities and cost-effectiveness compared to competing technologies. A "technology" is defined as devices, equipment, related software, drugs, biotechnologies, procedures, and therapies; and systems used to diagnose, treat, or monitor patients. The technology assessment process is discussed in Chapters 30, 32, and 33.

Technology assessment is not the same as technology acquisition/procurement or technology planning. The last two are processes for determining equipment vendors, soliciting bids, and systematically determining a hospital's technology-related needs based on strategic, financial, risk management, and clinical criteria. The informational needs differ greatly between technology assessment and the acquisition/procurement or planning processes. This section focuses on the resources that are applicable to technology assessment.

Worldwide, there are nearly 400 organizations (private, academic, and governmental) that provide technology assessment information, databases, or consulting services. Some are strictly information clearinghouses, some perform technology assessment, and some do both. For those that perform assessments, the quality of the information generated varies greatly from superficial studies to in-depth, well-referenced analytical reports. In 1997, the U.S. Department of Health and Human Services' Agency for Healthcare Research and Quality (AHRQ), formerly known as the Agency for Health Care Policy and Research, designated 12 "Evidence-based Practice Centers" (EPC) to undertake major technology assessment studies on a contract basis. Each of these EPCs is noted in the list below, and general descriptions of each center may be viewed on the AHRQ's web site: <http://www.ahrq.gov/clinic/epc>.

Language limitations are a significant issue. In the final analysis, the ability to undertake technology assessment requires assimilating vast amounts of information, most of which exists only in the English language. Technology assessment studies published by the International Society for Technology Assessment in Health Care (ISTAHC), by the World Health Organization, and other umbrella organizations are generally written in English. The new International Health Technology Assessment database being developed by ECRI in conjunction with the U.S. National Library of Medicine contains more than 30,000 citations to technology assessments and related documents.

Below are the names, mailing addresses, and web addresses of some of the most prominent organizations that undertake technology assessment studies:

Health Care Quality and ISO 9001:2000

David A. Simmons
Health Care Engineering, Inc.
Glen Allen, VA

“ISO” is recognized as the short name for the International Organization for Standardization (IOS), an international agency located in Geneva, Switzerland, consisting of almost 100 member countries. Each country, no matter large or small, has one “equal” vote. The United States’ representative to ISO is the American National Standards Institute (ANSI). From 1994 to 2000, the core of the ISO 9000 Quality Systems Standard was a series of five international standards that provide guidance in the development and implementation of an effective quality management system. Not specific to any particular product or service, these standards are applicable to manufacturing and service industries alike. In 2000, the International Standards Association in Geneva, Switzerland revised the international ISO Core Standards. Effective in 2000, there are four documents; ISO 900:2000, ISO 9001:2000, ISO 9004:2000 and ISO 19011. ISO 9002:2000 is a requirement standard. ISO 9000:2000, ISO 9004:2000 and ISO 19011 are guideline documents.

A quality management system refers to the activities one carries out within one’s organization to satisfy the quality-related expectations of one’s customers. To ensure that an organization has a quality management system in place, customers or regulatory agencies may insist that the organization demonstrate that its quality management system conforms to the ISO 9001:2000 quality system model. Then, the customer “second party” or an independent “third party” registrar goes to the organization to “audit”, or verify, that such a system is in place. When a registrar determines that the organization fulfills the requirements of the ISO 9001:2000 standard, that organization becomes “registered” and receives a certificate that is accepted by many of the organization’s customers. Organizations that are not concerned with becoming registered might, nevertheless, want to comply with ISO 9001:2000.

This chapter describes the ISO 9000 Core Standards, ISO 9001:2000, in particular, and the Industry Workshop Agreement, which aided in the expeditious development of the standards. The standard’s application to health care and rationale for adoption will be explained. Health care quality management principles are illustrated in the light of ISO 9001:2000.

The ISO 9000 Core Standards

There are four Core Documents, as follows:

ISO 9000:2000 provides quality management principles and fundamentals. It describes what the series is about, and lists basic definitions of terms for use by any organization.

ISO 9001:2000 states requirements for quality management systems when it is necessary to demonstrate that an organization is capable of effectively meeting customer and regulatory requirements, such as those of the Joint Commission on the Accreditation of Health care Organizations (JCAHO), the National Committee for Quality Assurance (NCQA), and the URAC, or state and federal requirements.

ISO 9004:2000 provides guidance for establishing a quality management system that goes beyond ISO 9001 requirements to meet and exceed customer expectations efficiently.

ISO 19011 provides guidance on planning and conducting quality audits.

Clauses in the ISO 9001 Quality Systems Standard

ISO 9001:2000 consists of five primary clauses that contain 23 subclauses. These requirements spell out what an organization (and, possibly, an individual in that organization) must do to conform to the standard. All of the requirements must be documented and controlled. The clauses are as follows:

Sections 1 through 3—Administrative and Actual Quality Management System Standards
Section 4—Quality Management System

- 4.1 General Requirements
- 4.2 Documentation requirements
 - 4.2.1 General
 - 4.2.2 Quality Manual
 - 4.2.3 Control of Documents
 - 4.2.4 Control of Records

Section 5—Management Responsibility

- 5.1 Management Commitment
- 5.2 Customer Focus
- 5.3 Quality Planning
- 5.4 Planning
 - 5.4.1 Quality Objectives
 - 5.4.2 Quality Management System Planning
- 5.5 Responsibility, Authority and Communication
 - 5.5.1 Responsibility and Authority
 - 5.5.2 Management Representative
 - 5.5.3 Internal Communication
- 5.6 Management Review
 - 5.6.1 General
 - 5.6.2 Review Input
 - 5.6.3 Review Output

Section 6—Resource Management

- 6.1 Provision of Resources
- 6.2 Human Resources
 - 6.2.1 General
 - 6.2.2 Competence, Awareness and Training
- 6.3 Infrastructure
- 6.4 Work Environment

Section 7—Product Realization

- 7.1 Planning of Product Realization
- 7.2 Customer-related Processes
 - 7.2.1 Determination of Requirements related to the Product (or Service)
 - 7.2.2 Review of Requirements Related to the Product (or Service)
 - 7.2.3 Customer Communication
- 7.3 Design and Development
 - 7.3.1 Design and Development Planning
 - 7.3.2 Design and Development Inputs
 - 7.3.3 Design and Development Outputs
 - 7.3.4 Design and Development Review
 - 7.3.5 Design and Development Verification
 - 7.3.6 Design and Development Validation
 - 7.3.7 Control of Design and Development Changes
- 7.4 Purchasing
 - 7.4.1 Purchasing Process
 - 7.4.2 Purchasing Information
 - 7.4.3 Verification of Purchased Product
- 7.5 Production and Service Provision
 - 7.5.1 Control of Production and Service Provision
 - 7.5.2 Validation of Processes for Production and Service Provision
 - 7.5.3 Identification and Traceability
 - 7.5.4 Customer Property
 - 7.5.5 Preservation of Product
- 7.6 Control of Monitoring and Measurement Devices

Section 8—Measurement, Analysis and Improvement

- 8.1 General
- 8.2 Monitoring and Measurement
 - 8.2.1 Customer Satisfaction
 - 8.2.2 Internal Auditing
 - 8.2.3 Monitoring and Measurement of Process
 - 8.2.4 Monitoring and Measurement of Product
- 8.3 Control of Nonconforming Product
- 8.4 Analysis of Data
- 8.5 Improvement
 - 8.5.1 Continual Improvement
 - 8.5.2 Corrective Action
 - 8.5.3 Preventive Action

The model of a process-based quality management system shown in Figure 119-1 illustrates the process linkages presented in clauses 4 to 8. This illustration shows that interested parties play a significant role in defining requirements as inputs. Monitoring the satisfaction of interested parties requires the evaluation of information relating to the perception of interested parties as to whether the organization has met their requirements. The model shown in Figure 119-1 does not show processes at a detailed level.

Industry Workshop Agreement (IWA1)

In 2000, the IOS acknowledged that the standards-writing and -revision processes were time consuming, often taking years. ISO 9000 was, as are all ISO Systems Standards, quite generic in nature, by design. During the 1990s, some industries in the United States felt that ISO 9000 was too generic, and they proceeded to develop their own industry-specific standards without the direct approval of, or processing by, the IOS in Geneva. The automotive industry, for example, developed QS 9000 for itself. The aerospace industry created AS 9000. The telecommunications industry created TL 9000. The health care industry recognized a need to have some form of quality-system standard. In 1999, the author, as chair of the Health Care Division of the American Society of Quality, created a standards committee with the expressed intent of initiating activity of creating a health care industry standard, tentatively to be called HC 9000. Over the next two years, the Health Care Division of the American Society of Quality (ASQ), with participation and support from the Automotive Industry Action Group (AIAG), continued to develop a draft standard for process improvements in health care organizations. The guidelines that they developed were based upon the same quality management principles as ISO 9001 and encouraged the adaptation of a process approach to quality management.

During this same period, the IOS decided that it had to take action to attempt to reduce the proliferation of industry-specific standards. It developed and implemented a new “fast track” process that could produce industry specific “standards” in a much faster way without compromising the already-existing IOS system and procedures for generating standards. It came up with the Industry Workshop Agreement (IWA). The ASQ Health Care Division and the AIAG recognized that this could be a faster way to put a health care document in place, and it decided to accept the IWA. Furthermore, as there was no pre-existing health care quality system standard in place, they decided that the document needed to be comprehensive in scope and detail. The committee decided to base the health care quality management systems standard on ISO 9004:2000, the guidance document.

The IWA process calls for the creation of a draft document, or IWA draft, by the creating industry or special interest group. Next, the group is expected to call a public “workshop” to review, revise, and come to a consensus. When a consensus is achieved, the group is required to vote within a 60-day period. A three-day IWA Health Care Workshop was held in January, 2000 in Detroit, Michigan. During the 60-day voting period, the members overwhelmingly voted for approval of the IWA. The IWA was sent to the IOS in Geneva and has been issued as the first Industry Workshop Agreement, IWA-1. This IWA-1 document is the first quality management standard (QMS) developed for health care provider organizations. It is based on two ISO Standards; ISO 9001:2000, Quality Management Systems—Requirements, and ISO 9004:2000, Quality Management Systems—Guidelines for Performance Improvement. ISO 9001:2000 is the basic, or core, Standard for Quality Management Systems. ISO 9004:2000 is a more expansive standard that provides guidance for implementing ISO 9001:2000. While JCAHO imposes prescriptive standards on health care providers, the three ISO standards are voluntary and are used to implement or to modify a quality management standard for existing organizations, based on the uniqueness of their particular system and structure. ISO is a valuable system tool to assist in better, faster, and less costly way to achieve JCAHO accreditation.

With the JCAHO participating in the development process, the ASQ guidelines, in the form of IWA-1, meld JCAHO standards with the ISO standards requirements within JCAHO to provide guidance on the application and improvement of quality management systems in health care organizations. This is demonstrated by the adoption of specific ISO 9001:2000 requirements into forthcoming JCAHO medications standards.

Health Care Applications

The adoption and use of the ISO 9001:2000 series standards and guidelines by institutional, managed care, service providers, and physician practice health care providers can result in many benefits. This material contains several unique approaches useful in the implementation of ISO 9001:2000 in the health care setting.

As everyone in the health care community knows, medical errors are an ongoing problem for which there has been little or few major breakthroughs toward solution or reduction (IOM, 2000). It is well understood that one of the ways to reduce medical system failures is the proper collection, aggregation, and analysis of several categories of data. Such analysis can then lead to root cause analysis (RCA) and continuous quality improvement (CQI) through the use of Plan-Do-Check-Act (PDCA) cycles. The Institute of Medicine’s March 2001 report, *Crossing the Quality Chasm: A New Health System for the 21st Century*, calls for “the elimination of handwritten clinical information by 2010 and refocusing the health care system on treating chronic illness” (IOM, 2001).

In an effort to improve the health care management system and to reduce medical errors, there have been a few small and localized attempts to use hand-held personal data assistants (PDAs) to collect, store, and analyze clinical and administrative data. The ultimate solution is to combine the use of hand-held devices that transmit data in real time with larger, fixed computer systems. These systems can be those of an institution or of an applications service provider (ASP). Health care professionals can access full and complete real-time data in order to treat patients more effectively and, in the process, to identify and reduce medication and medical errors.

Institutional health care providers are those hospitals, medical centers, and clinics that currently submit to, and comply with, JCAHO for the primary purpose of obtaining Medicare reimbursement for providing health care services to Medicare patients. The Medicare system is administered by the Federal Department of Human Services Department’s Centers for Medicare and Medicaid Services (CMS); formerly the Health Care Finance Administration (HCFA).

Because CMS does not have sufficient staffing to perform site surveys of all Medicare provider facilities, CMS has given the JCAHO what is known as “deemed status,” which means that if a hospital or dissimilar institutional facility or program has received JCAHO accreditation, CMS will accept that accreditation in lieu of its own survey. CMS does bear primary survey responsibility under the law, however can and has delegated survey and compliance monitoring to state or other authorized health care jurisdictional authorities. The benefit to the use of ISO 9001:2000 compliance and registration is that once ISO 9001:2000 is implemented, the very nature of the process assures continuous quality improvement (CQI), whereby problems and process variations are addressed quickly and permanently. With ISO 9000 registration, periodic internal and external audits are needed, to monitor continuing compliance. There is relatively little interruption in the delivery of health care as experienced with the three-year JCAHO accreditation cycle. Those who work in the hospital, long-term care facility, or clinical environment are well aware of the typical six- to nine-month preparation process that takes place before a JCAHO survey. Health care, allied health care professionals, and management leaders are diverted from providing health care and spend considerable time “gearing up” for surveys. The number of hours converted into dollars is considerable, as is the cost to the institution for the actual JCAHO survey.

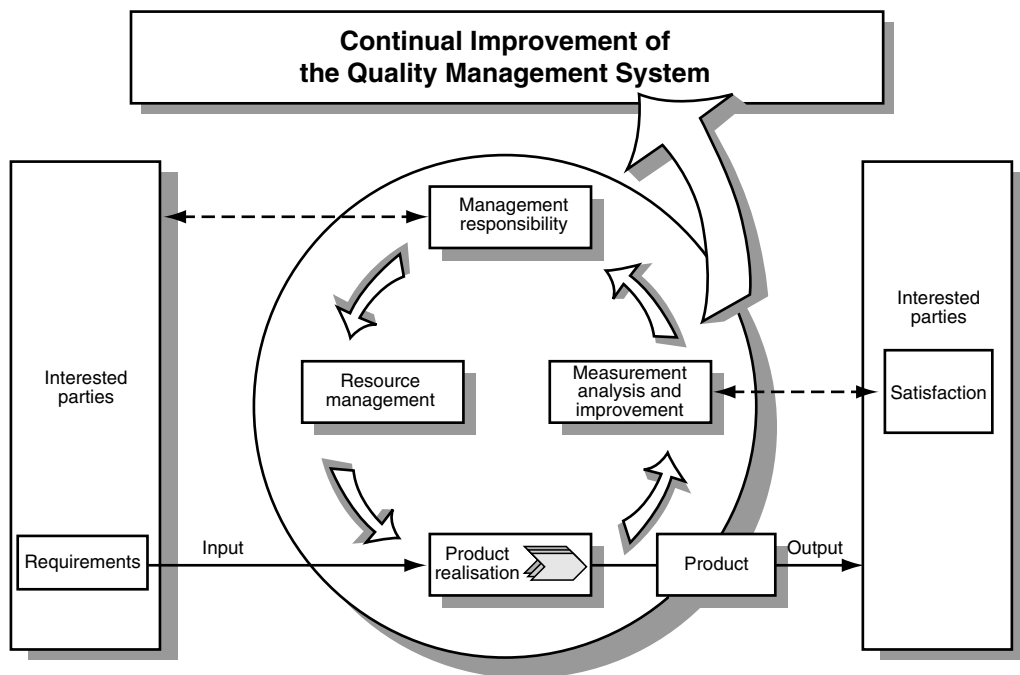

Figure 119-1 Model of a process-based quality management system showing key, value-added activities information flow.

Managed care and health maintenance organizations (HMO) experience similar kinds of problems in preparation for the NCQA Health Plan Employer Data and Information Set (HEDIS) Report Card System. NCQA performs both accreditation and performance measurement. While the standards are different, the “process” is essentially the same as far as the long lead time and costly preparation time and survey costs.

Physician group practices (e.g., institutional provider organizations (IPOs), preferred provider organizations (PPOs)) can benefit for two significant reasons. First, implementation of the ISO 9001:2000 process can create a more efficient practice that can identify problems early and can initiate corrective action to solve problems more quickly and to better monitor, control, and reduce costs in the process. The second major reason is that a practice that is ISO 9001:2000-registered can point to its registration as a benchmark of an efficient and controlled operation. Increasingly, this is what insurance companies, payers, and larger IPOs seek when assessing physician group practice providers.

Medical equipment service providers include the original equipment manufacturers (OEM), in-house clinical engineering programs, independent service organizations (ISOs), and equipment remanufacturers. The U.S. Food and Drug Administration requires medical equipment manufacturers to comply with a federal regulation known as “Good Manufacturing Practice” (GMP). The FDA is currently attempting to pass legislation to require all such service providers to comply with laws that will impose requirements upon providers in the area of tracking of devices after sale and during the life of the medical device until it is replaced. Given the large volume of medical devices in use today, as well as their portable nature, the ability to comply with such requirements is virtually impossible. New legislation would prove to be a cross between the Safe Medical Device Amendments of 1990 and the GMPs. After significant service-provider protests, the FDA has retreated for the time being, while urging the service providers to implement a quality-systems standard of their own development or to face GMPs or equivalent legislation. ISO 9001:2000 is a quality management system that can solve the problem with less effect on service costs than any other system currently available can.

Overall, it has been well demonstrated that if a health care provider is ISO 9001:2000 qualified or registered, any other survey process will be much simpler and less costly regarding preparation and compliance demonstration. Although ISO 9001:2000 registration is not intended to replace JCAHO or NCQA accreditation, it does make the compliance-demonstration process appreciably less difficult, less time-consuming, and less costly.

Rationale for Adoption of ISO 9001:2000 in Health Care

Health care organizations adopt ISO 9001:2000 standards for a variety of different reasons. An organization’s decision to do so may include any of the following reasons:

- To improve a quality system
- To minimize repetitive auditing by accrediting organizations
- To improve subcontractors’ and vendor’s performance

Both the clinical engineer and the organization benefit because use of ISO 9001:2000 serves as a basis to:

- Achieve better understanding of all quality practices throughout the organization
- Ensure continued use of the required quality system year after year
- Improve documentation and records
- Improve quality awareness
- Strengthen both supplier and customer confidence and relationships
- Yield cost savings and improve profitability
- Form a foundation for improvement activities within total quality management (TQM).

Complying with ISO 9001:2000 requirements does not indicate that every product or service meets the customers’ requirements. It merely means that the quality system in use is capable of meeting them. That is why an organization must continuously assess customer satisfaction and must constantly improve the processes that produce the products or services.

Health Care Quality Management Principles

The following principles have been identified within the ISO 9001:2000 and IWA-1 standards to facilitate achievement of quality objectives:

1. Customer Focus

- Understanding current customer needs
- Understanding future customer needs
- Meeting customer requirements
- Striving to exceed customer expectations

2. Leadership

- Establishing unity or purpose and direction for the organization
- Establishing the organization’s internal environment

3. Involvement of People

- Developing abilities fully
- Using abilities toward maximum benefit

4. Process Approach

- Managing resources as a process
- Achieving desired results more efficiently

5. Systems Approach to Management

- Identifying
- Understanding and managing the interrelated processes of a system to reach objectives effectively and efficiently

6. Continual Improvement

- Making improvement a permanent objective

7. Factual Approach to Decision Making

- Analyzing data and information logically

8. Mutually Beneficial Supplier Relationships

- Creating value through mutually beneficial, interdependent relationships

Because every health care organization is different, the implementation of ISO 9001:2000 will be different in each organization. The following three basic and fundamental requirements exist:

1. Document processes that affect quality
2. Retain records and data that describe the product or service
3. Ensure that processes produce consistent quality

While JCAHO and NCQA have prescriptive standards, ISO does not have specific requirements in its quality management system. Each organization must develop its own system and then must comply with it. The imperatives that describe how ISO 9000 and, now, ISO 9001:2000 are to be implemented can be expressed as the following:

*Say what you do.
Do what you say.
Prove it.
Improve it.*

ISO 9001:2000 Documentation

Because documentation is so important to ISO 9001:2000 compliance, it is important to understand the levels of documentation. There are four levels, as follows:

Level I: Quality manual

The statement of the organization’s quality, written by managers from top-level management and the quality department.

Level II: Procedures

Defines activities at the department level and written by department managers and supervisors.

Level III: Work/job instructions

Describes ways in which jobs are accomplished; are usually written by the operators and trainers.

Level IV: Other documentation (records)

Quality records include such items as forms (both hard copy and electronic), tags, labels, and other such forms of records that are usually created by quality and/or other middle managers. Level II procedures are the backbone of quality documentation because they are the documents that define and describe processes of the operation of hospital and health care provider operations. Typical process procedures should contain:

- Purpose/objective: The aim of the procedure
- Scope: What the procedure does and does not cover
- Responsibilities: Who, by job function, has responsibilities for specific tasks or actions
- References: To all documents covered under the procedure
- Definitions: Key terms or acronyms
- Procedures: Description of the actions or tasks to be carried out; by whom; and in what sequence
- Documentation: Documentation and records that are needed

Historically, most Level II process procedures are created in the form of flow charts rather than text documents.

Summary

The new ISO 9001:2000 standard stresses documentation control. Organizations that implement ISO 9001:2000 can do so by using by using the new ISO IWA 1, Health Care Guideline Document, which is an adaptation of ISO 9004:2000, specifically developed for health care applications and improve your document control system. This approach to implementing ISO 9001:2000 requires less consultation time and provides a comprehensive, integrated solution to address “what to do,” “how to do it,” and “how to be able to do it.”

The goal of this document is to aid in the development or improvement of a fundamental quality management system for health service organizations, providing for continuous improvement, emphasizing error prevention and the reduction of variation and organizational waste (e.g., non-value-added activities).

This guide incorporates much of the text of ISO 9004:2000—"Quality Management Systems—Guidelines for Performance Improvements" and provides guidance on quality management systems, including the processes for continual improvement that contribute to the satisfaction of a health service organization's customers and other interested parties. The quality management system should provide for all customers of a health service organization, regardless of the product or service provided.

Hospital Facilities Safety Standards

Gerald Goodman

Assistant Professor, Health Care Administration
Texas Women's University
Houston, TX

The numerous hospital facilities safety standards in the United States include statutes promulgated the United States Congress and state legislatures. They also include those regulations developed by private agencies and designated as national standards because of their adoption by public agencies. This chapter addresses the major standard making organizations involved in hospital-facility safety. Because regulatory responsibility for device and facility safety and employee safety overlap, these regulatory programs are included for completeness.

Public facility safety standard making agencies include the Health Care Financing Administration (HCFA) and the Occupational Safety and Health Administration (OSHA). Private standard making agencies include the Joint Commission on Accreditation of Health Care Organizations (JCAHO) and the National Fire Protection Association (NFPA).

National Fire Protection Association

The mission of the international nonprofit National Fire Protection Association (NFPA) is to reduce the worldwide burden of fire and other hazards on the quality of life by providing and advocating scientifically based consensus codes and standards, research, training, and education. NFPA's focus on true consensus has helped the association's code-development process to earn accreditation from the American National Standards Institute (ANSI).

ANSI accreditation means that codes and standards developed by the NFPA have achieved the status of national consensus standards. Because of this standing, government agencies and many private organizations automatically adopt NFPA codes and standards as their own. HCFA and JCAHO use NFPA codes, as do the majority of state and local fire authorities.

The codes and standards of the NFPA apply to life safety and fire safety and, under the umbrella of fire safety, NFPA documents contain important design features for medical device safety. These include codes related to the use of medical gases, hyperbaric chambers, and high electrical-frequency devices.

Authority with Jurisdiction

The term "authority with jurisdiction" is not a facility safety organization *per se*, but rather is a term used by the NFPA to indicate the responsible local authority that takes regulatory responsibility for life safety compliance. Typically, this responsibility is held by a

local fire marshal's office or a similar governmental entity. NFPA standards refer to the authority with jurisdiction in order to provide businesses with a specific local authority for interpreting compliance with life safety codes.

NFPA Code Revision Date

NFPA codes and standards are revised periodically. However, regulatory organizations including the JCAHO, HCFA, and the authority with jurisdiction adopt a specific revision of an NFPA code as the code they will enforce. The most recent NFPA code will not necessarily be the one enforced. In fact, government agencies such as HCFA cannot respond quickly to code changes. It is possible to find a government agency enforcing a code that is several revisions behind the present version.

Joint Commission on Accreditation of Healthcare Organizations

The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) evaluates and accredits more than 17,000 health care organizations and programs in the United States (see Chapter 121). An independent, not-for-profit organization, JCAHO is the nation's predominant standards-setting and accrediting body in health care. Since 1951, JCAHO has developed state-of-the-art, professionally based standards and has evaluated the compliance of health care organizations against these benchmarks (JCAHO, 2000). JCAHO accreditation is recognized nationwide as a symbol of quality that reflects an organization's commitment to meeting certain performance standards. To earn and maintain accreditation, an organization must undergo an on-site survey by a JCAHO survey team at least every three years. Laboratories must be surveyed every two years.

JCAHO has separate accreditation criteria and manuals for each of its types of provider organizations. These include general, psychiatric, children's, and rehabilitation hospitals; health care networks, including health maintenance organizations (HMOs), integrated delivery networks (IDNs), preferred provider organizations (PPOs), and managed behavioral health care organizations; home care organizations, including those that provide home health services, personal care and support services, home-infusion and other

pharmacy services, durable-medical equipment services and hospice services; and nursing homes and other long-term-care facilities.

The JCAHO standards for hospitals are typical of those for other provider types and will be used here for discussion purposes. The principal section of the JCAHO hospital accreditation manual that is relevant to facility safety is the chapter on “The Environment of Care” (JCAHO, 2000). The Environment of Care (EC) chapter includes those requirements related to device safety and life safety. Responsibilities of the clinical engineer may cross over to aspects of the EC chapter typically included in a facilities management program, such as the pneumatic tube system or fire alarm system.

The key facilities safety document under the JCAHO EC is the “Statement of Construction” (SOC). This document is intended to be an ongoing, historical summary of the facility’s compliance with the NFPA Life Safety Code (NFPA 101). The SOC brings into focus varying codes for fire alarm and suppression systems, building construction standards, building maintenance related to fire safety, and building occupancy characteristics such as obstructed fire exit corridors.

Standards under the EC for device and facility safety are summarized in Tables 120-1 and 120-2. JCAHO addresses Table 120-1 to clinical engineering and Table 120-2 to facilities management.

Table 120-1 Clinical Engineering: JCAHO Environment of Care (EC) Standard

<i>JCAHO section</i>	<i>Requirement</i>	<i>Source of data</i>
EC.1.8	A management plan addresses medical equipment.	<ol style="list-style-type: none"> 1. Medical equipment management plan 2. Minutes of a medical–equipment-safety subcommittee 3. Clinical engineering plan for providing patient care
EC.2.1	Personnel can describe their role in each of the EC plans: <ul style="list-style-type: none"> ● Safety ● Fire response ● Hazardous materials ● Emergency preparedness ● Utility outage ● Technical-training records ● Process for reporting medical equipment problems ● Whom to contact for an after-hours medical equipment emergency 	<ol style="list-style-type: none"> 1. Job descriptions 2. Required education matrix 3. Competency checklist 4. Education department training records and individual personnel files
EC.2.7	The medical equipment management plan is implemented.	Minutes of a medical equipment safety subcommittee

From 2000 JCAHO Manual. Sections can change with later revisions.

Health Care Financing Administration

The Health Care Financing Administration (HCFA) is a federal agency within the U.S. Department of Health and Human Services. HCFA administers the Medicare and Medicaid programs. Recently, HCFA was renamed the Centers for Medicare & Medicaid Services. HCFA regulates all laboratory testing (except research) performed on humans in the United States. Approximately 158,000 laboratory entities fall within HCFA's regulatory responsibility.

HCFA has a number of quality assessment and performance improvement initiatives related to improving the quality of health care provided to Medicare, Medicaid and Child Health Insurance Program beneficiaries. These include the following:

- Developing and enforcing standards through surveillance
- Measuring and improving outcomes of care
- Educating health care providers about quality improvement opportunities
- Educating beneficiaries to make good health care choices

The surveillance program includes the hospital-safety standard compliance activities of HCFA, principally life safety compliance using standards developed by the National Fire Protection Association. HCFA surveillance is typically performed by state hospital-licensing personnel. HCFA's regulatory programs can be found in Title 42 of the Code of Federal Regulations (CFR).

Occupational Safety and Health Administration

The Occupational Safety and Health Administration (OSHA) is responsible for establishing and enforcing workplace-safety rules. In an era of increased focus on patient safety, it is important to remember that OSHA concerns itself with employee safety

only. OSHA safety regulations do not address facility safety *per se*. Rather, OSHA regulations specify safety practices that are to be enforced while maintaining the facility. These regulations are typically identified for specific hazards, such as respiratory protection when using aerosolized paint. OSHA does have a "general duty clause," which is a catch-all regulation that requires employers to provide employee-safety programs regarding hazards of which the employers should have been aware, even if no specific safety program is identified.

Safety programs under OSHA that are particularly relevant to clinical engineering include those that concern employee protection from blood-borne pathogens and rules that relate to worker protection from energized equipment, ladder safety, and hearing and eye protection when using tools such as grinders and drills.

Rules regarding blood-borne pathogens include those that are applicable to all hospital personnel who have the potential for exposure to blood and body fluids from direct patient contact. They also include requirements that clinical engineering departments develop and enforce rules for the decontamination of patient equipment prior to repair. Rules for blood-borne pathogens can be found in 29 CFR 1910.

OSHA requires that worker protection be provided when repairs are being made to "energized" devices. These can be powered by an electrical, pneumatic, or other power source. The rules are classified as "lockout-tagout" rules. A typical example for the application of lockout-tagout rules is the repair of any permanently wired electrical equipment such as X-ray systems. The rules do not apply to those devices that can be disconnected from their power source prior to repair. In such cases, department policy must be clear that such devices must not be repaired while connected to their power source unless specifically approved on a case-by-case basis.

JCAHO Accreditation

Britt Berek

JCAHO
Oakbrook Terrace, IL

The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) is an independent, non-profit organization committed to improving the level of health care delivery in the United States and abroad. The overarching purpose of JCAHO is to continuously improve the safety and quality of care provided to the public in organized delivery settings. Setting standards and evaluating whether organizations seeking accreditation comply with those standards accomplishes this goal.

JCAHO History

Inspection of hospitals in the United States began as early as 1918 under the "Hospital Standardization Program" developed and administered by the American College of Surgeons (ACS). Although the first standards used by the ACS consisted of a single page of requirements, fewer than a third of the initial group of hospitals inspected were able to successfully meet them. As interest in hospital standardization and inspection became more prevalent, other professional medical societies became involved in hospital standards and compliance activities in addition to ACS, including the American Hospital Association (AHA), American Medical Association (AMA), and American College of Physicians (ACP).

The Joint Commission on Accreditation of Hospitals (JCAH) was founded in 1951, with the joint collaboration of the four leading provider organizations (i.e., the ACS, AMA, CMA, and ACP) as a non-profit organization that provided voluntary accreditation for hospitals.

In 1953, the JCAH published their first standards for hospital accreditation. By 1960, 2900 hospitals participated in the accreditation program. In 1965, Congress passed the Social Security Amendments of 1965 (commonly known as the Hill-Burton Act/Medicare Act) with a provision that hospitals accredited by JCAH are also in compliance with the Medicare Conditions of Participation for Hospitals and can participate in the Medicare and Medicaid programs. The JCAHO currently accredits the majority of hospitals in the United States, largely because of this accreditation arrangement. In addition, JCAHO has expanded the number and types of health care organizations it accredits, and in 1987 it changed its name to the Joint Commission on the Accreditation of Healthcare Organizations (JCAHO) to reflect this expanded scope of activities.

The JCAHO now accredits more than 18,000 health care organizations in the United States and many other countries. Accredited organizations include hospitals, long-term care facilities, ambulatory care facilities, home care organizations, clinical laboratories, and behavioral health care facilities.

Benefits of Accreditation

In addition to meeting the requirements for participation in the Medicare and Medicaid program for hospitals, JCAHO accreditation has accrued a number of other benefits for accredited organizations over the years. Health care organizations seek JCAHO accreditation for benefits including the following:

- Enhanced community confidence
- Provision of a progress report for the public
- Stimulation of the organization's quality improvement efforts
- Assistance with professional staff recruitment
- Expedition of third-party payment
- Fulfillment of state licensure requirements
- Possible improvement of liability insurance premiums
- Favorable influence on managed care contract decisions

By seeking accreditation, an organization agrees to be measured against national standards set by health care professionals. An organization that is "accredited" demonstrates that it substantially complies with JCAHO standards and continuously works to improve the care and services it provides.

The Accreditation Process

Trained surveyors evaluate each health care organization's compliance with JCAHO standards and identify the organization's strengths and weaknesses. This evaluation is performed at the organization. The surveyors' goal is not merely to find problems, but also to educate and advise; so health care organizations can improve. Summary results of the surveys are posted on the JCAHO's website for public disclosure.

Most on-site reviews occur every three years (except for clinical labs on two-year cycles). However, an organization may also undergo a number of unscheduled, intra-cycle events. These special surveys may be performed "for-cause" if the organization is identified for an on-site investigation through the JCAHO's Quality Monitoring process, or if the organization is selected for a random unannounced survey. These events may be announced (scheduled with the organization's knowledge) or unannounced (scheduled without the organization's knowledge as a validation and quality check, or as part of the investigation of a potentially serious accreditation issue).

Departments and Programs

The JCAHO currently employs approximately 500 field surveyors that conduct on-site surveys at organizations seeking accreditation or re-accreditation. In addition, there are approximately 500 other employees in the central office in Oak Brook, Illinois, that support the field surveyors, develop or improve accreditation programs and standards, and assist organizations in completing accreditation activities.

In the process of obtaining accreditation, organizations may interact with a number of departments and programs at the JCAHO's central office. These departments include the following:

Accreditation Operations

The Division of Accreditation Operations (AO) administers accreditation services. Each organization seeking accreditation will be assigned to an account representative, who will guide the organization through the accreditation process from completing the application, scheduling the survey, assigning surveyors, completing the on-site event, and assisting with the survey report, as well as handle any subsequent follow-up. The JCAHO account representative will typically interact with a designated organizational liaison. The designated liaison is frequently involved in quality management or a similar administrative function.

Office of Quality Monitoring

The Office of Quality Monitoring (OQM) receives and evaluates sentinel events and complaints from organizations, outside agencies, media, and the public. Organizations may need to formally respond to certain types of serious incidents. "Sentinel events" are rare, but serious, events that result in patient death or significant disruption of health care delivery. Analysis of these incidents is the source of "Sentinel Event Alerts" and the "National Patient Safety Goals" that are provided to health care organizations to assist them in reducing the odds of these events occurring or recurring.

Department of Education Programs

The Department of Education Programs (DEP) provides educational programs and teleconferences. DEP also maintains a speaker's bureau that coordinates the assignment of JCAHO speakers for external organizations.

Publications

To assist organizations in understanding and complying with JCAHO standards, the Publications department provides printed education materials and software. A catalog is available on the JCAHO's web site (www.jcaho.org or www.jcrinc.com) through "Infomart."

JCAHO Resources

On-site consulting services and international accreditation activities are provided by a for-profit subsidiary called JCAHO Resources (JCR). Organizations may request mock surveys and other consultative services to identify problem areas and to better prepare for their surveys.

Oryx

In 1997, the Oryx initiative was launched in an effort to integrate clinical outcomes and other performance data into the accreditation process. Oryx data are transmitted to JCAHO for integration and analysis. Currently, Oryx data focus on clinical measures.

Accreditation Decisions

The report that accompanies each accreditation decision details areas where an organization's performance must improve, and includes recommendations for how to meet the standards. If a health care organization has problems, it may receive accreditation contingent on those problems being fixed in a reasonable amount of time. The JCAHO closely monitors organizations with more substantial deficiencies to ensure that they are trying to solve their problems.

The JCAHO currently has eight accreditation-decision categories.

1. Accreditation without Type I Recommendations

Effective January 1, 2001, Accreditation without Type I Recommendations (previously known as Accreditation), is awarded to a health care organization that complies with applicable JCAHO standards in all performance areas.

2. Accreditation with Type I Recommendations

Effective January 1, 2001, Accreditation with Type I Recommendations (previously known as Accreditation with Recommendations for Improvement), is awarded to a health care organization that complies with applicable JCAHO standards in most performance areas, but has deficiencies in one or more areas or accreditation policy requirements that require resolution within a specified time.

3. Provisional Accreditation

An accreditation decision that results when a health care organization complies with a subset of standards during a preliminary on-site evaluation. This decision remains in effect until another official accreditation decision category is assigned, approximately six months later, based on a complete survey against all applicable standards.

4. Conditional Accreditation

An accreditation decision that results when a health care organization performs as follows:

- Fails to comply with applicable JCAHO standards in multiple performance areas, but is believed to be capable of achieving acceptable standards compliance within a stipulated time period
- Remains unable or unwilling to comply with one or more JCAHO standards
- Fails to comply with one or more specified accreditation policy requirements

5. Preliminary Denial of Accreditation

Effective January 1, 2001, Preliminary Denial of Accreditation (previously known as Preliminary Nonaccreditation), results when justification is found to deny accreditation to a health care organization because it has failed to comply with applicable JCAHO standards in multiple performance areas or failed to comply with accreditation policy requirements, or for other reasons. This accreditation decision is subject to subsequent review.

6. Accreditation Denied

Effective January 1, 2001, Accreditation Denied (previously known as Not Accredited), results when a health care organization has been denied accreditation. This accreditation decision becomes effective only when all available appeal procedures have been exhausted.

7. Accreditation with Commendation

Accreditation with Commendation, (eliminated effective January 1, 2000), was awarded to a health care organization that demonstrated more than satisfactory compliance with applicable JCAHO standards in all performance areas on a complete accreditation survey. Although this decision category has been discontinued as of January 1, 2000, organizations awarded this decision as a result of surveys conducted during 1997, 1998 and 1999 will retain this designation until their next complete surveys, unless it is lost based on an intracycle evaluation.

8. Accreditation Watch

Accreditation Watch, (though not a separate accreditation decision) is a publicly disclosable attribute of an organization's existing accreditation status. An organization is placed on Accreditation Watch when a sentinel event has occurred and a thorough and credible root cause analysis of the sentinel event, with an action plan, has not been completed within a specified time. Following JCAHO determination by that the organization has conducted an acceptable root cause analysis and developed an acceptable action plan, the Accreditation Watch designation is removed from the organization's accreditation status.

The reader is encouraged to see any of the JCAHO accreditation manuals for additional information on accreditation decisions, policies, and procedures (www.JCAHO.org).

JCAHO Standards

JCAHO standards address a comprehensive array of a health care organization's activities, from the medical staff to the care and treatment of patients, even the physical environment. For the hospital program alone, the accreditation manual standards that may each contain five to ten attributes. Chapters that relate to specific structures and functions

within an organization organize this range of standards. Compliance with all the standards in the accreditation manual requires a planned and continuous effort at all levels and department within the organization.

In 1995 under an initiative called the “Agenda for Change,” JCAHO standards were rewritten and reorganized to be less department-focused and more organization-focused. This shift required department managers to consider standards throughout the manual instead of a limited set for their departments. For example, clinical engineering personnel are now aware of requirements in the human resources, performance improvement, and infection control chapters, in addition to the standards in the environment of care chapter under Medical Equipment Management. Department managers should coordinate their compliance efforts with the organization’s accreditation liaison to ensure that all applicable standards are covered. The standards are constantly revised in order to be consistent with changes in health care delivery and environmental conditions. For example, emergency management standards emphasize bio-terrorism preparedness as a result of the events surrounding September 11, 2001.

The Environment of Care Standards

The standards that apply most directly to clinical engineers appear in the *Environment of Care* chapter (EC) and are known as the medical equipment management standards. The medical equipment sub-group is one of seven major sub-groupings of standards in the EC chapter. The other sub-groupings include: safety, security, emergency management, hazardous materials and waste, life safety, and utilities management. In addition, supporting standards require each of these areas to be organized within a performance improvement framework.

The performance improvement element of the standards in the EC chapter follows a Design/Teach/Implement/Measure/Improve framework (see Table 121-1). Each of the seven major sub-groupings has a program design component, a teaching or educational component, an implementation and documentation component, a measurement and assessment component, and an improvement component. As a result, the seven areas will generate several of the same types of documents even though their specific content will differ.

For example, in the design step, the organization will need to develop a management plan for each of the seven EC areas. The management plan will describe how the organization will assign responsibility and carry out the necessary functions in each area as described by the JCAHO standard. The plan may reference organizational policies and procedures, describe reports, designate assignments, indicate reporting relationships, or reference relevant committees. Table 121-2 gives examples of how these EC documents may be organized in a moderately complex health care facility, such as a 200-bed hospital.

There are two ways to view the standards in the EC chapter that organizations may find useful. One view relates to the way in which all the standards within the chapter were designed to work together within the Design/Teach/Implement/Measure/Improve framework. The other way is to group the standards by the seven structural areas mentioned earlier, and consider the planning, teaching, implementation and documentation, and measurement, and strive to improve within a single functional area. The matrix of Table 121-1 shows how these two views can be presented simultaneously. The columns of Table 121-1 group the EC standards by functional area, while the rows group the standards by the Design/Teach/Implement/Measure/Improve cycle. Department managers should see the utility of dividing the EC standards by functional area, since responsibilities are typically divided this way within the organization.

Medical Equipment Management Standards

The EC’s medical equipment management standards are of greatest interest to clinical engineers. Although there other standards apply to department operations, as previously mentioned, the standards found in the medical equipment group are the most relevant.

Table 121-1 Common Elements in the EC Cycle: Design/Teach/Implement/Measure/Improve

Design	Management plans
Teach	Orientation continuing education
Implement	Routine activities failure correction
Measure and assess	Data collection
improve	Organization-wide performance improvement

Table 121-2 Organization of EC documents in a 200-bed hospital

JC function	Documents referenced in EC standards	Commonly referenced organization documents
Design	Management plan	Policy and procedures committees / Reporting structures personnel assignments
Teach		Training logs competency assessments
Implement	EC documentation	Test logs
Measure and access	Monitors of performance	Data related to operational features of EC activities (e.g., effectiveness of staff training and timely completion of maintenance activities)
Improve	Annual evaluation	Data on program effectiveness Management reports

The medical equipment management standards require programs to address and document the following tasks:

- Selecting and acquiring medical equipment
- Evaluating and minimizing physical and clinical risks
- Monitoring and acting on adverse incidents
- Reporting under mandatory programs (e.g., Safe Medical Devices Act of 1990)
- Establishing and assessing user and maintainer competency
- Establishing emergency procedures for equipment failures
- Maintaining an accurate inventory of all equipment
- Developing maintenance strategies for equipment
- Documenting maintenance activities

The medical equipment management plan should address the elements referenced in the standards, as appropriate. In larger settings, this will include all the elements (as described above); for smaller organizations certain elements may not apply, and the plan should not any discrepancies. The plan is meant to serve as a reference document that demonstrates the organizations understanding of the JCAHO’s requirements and shows how their operations will meet those requirements. The plan is a bridge between the JCAHO standards and the management of the organization. A well-constructed management plan should look like a business plan for department operations, and it will form the basis of subsequent on-going activities. Given the plan’s importance in the accreditation process and to the organization, the JCAHO standards require on-going monitoring and an annual evaluation of the plan’s scope, objectives, performance, and effectiveness. The continuous monitoring and re-evaluation is paramount to the JCAHO performance improvement model.

Key Program Attributes for Medical Equipment

The key program attributes for medical equipment are acquisition, inventory, maintenance strategies, and documentation of maintenance outcomes.

Acquisition

The organization must have a process for acquiring medical equipment. The process should address, at a minimum, elements of safety and clinical effectiveness. In order to minimize risk in subsequent use, the acquisition process is also an ideal time to address issues of patient safety and human factors.

Inventory

Organizations must decide which items to place into their structured medical equipment management plan (MEMP) inventory. The standards allow organizations to use risk-based criteria to decide which items may be included (or excluded) from this inventory.

If used, the organization must consider the following points:

- Equipment function (diagnosis, care, treatment, and monitoring)
- Physical risks associated with use
- Equipment incident history

Smaller organizations may choose to inventory all medical devices regardless of risk, but a larger organization will typically adopt inclusion criteria based on the attributes previously mentioned. Typically, a numerical algorithm is used to assign each type of equipment a “risk number,” which will be used for inventory inclusion. In addition, this “risk number” may subsequently be used to identify the higher risk items in prioritizing activities or contingency planning. The idea is that items with a higher risk score are more important for patient safety and should receive preferential attention.

Maintenance Strategies

Equipment included in the inventory section of the MEMP must be appropriately maintained to minimize risk to patients. The JCAHO standards allow organizations to determine which maintenance strategies will be most effective for their organization in providing functional, safe, and available equipment.

These maintenance strategies may include ways to provide effective corrective maintenance, preventive maintenance, and inspections for damage or abuse, predictive maintenance, calibration, or metered maintenance based on hours of use. The organization must measure effectiveness and decide which maintenance strategy or combination of strategies will yield the optimal result.

While most maintenance activities have traditionally included some element of periodic, scheduled maintenance, this tactic is not always optimal for contemporary medical equipment. For example, a modern solid-state patient bedside monitor may not have moving parts that require replacement or periodic adjustment. However, it may be susceptible to unpredictable electronic failure. To address this failure mode, a strategy that includes spare monitors for immediate replacement may be more effective than a quarterly inspection of a seemingly functional monitor. On the other hand, if organizational data indicated that, based on their use, the Ni-Cad batteries in a particular portable device fall below required capacity after two years, a program for scheduled battery replacement every 20 months may be used to reduce failures, improve reliability, and minimize risk to patients.

Documentation of Maintenance Outcomes

Results of maintenance activities must be documented in order to improve the effectiveness of maintenance strategies. This activity is critically important for life-support equipment and other high-risk devices. In addition, tracking the results of operational efforts in other areas (even low-risk activities) will ensure that limited resources are used as effectively as possible. Summary data will be reported to the safety committee, quality improvement committee, or similar leadership oversight committees to ensure minimization of patient risk. Surveyors often ask for maintenance data as a first step in exploring department compliance.

Future Accreditation Initiatives

The JCAHO is constantly striving for ways to improve the accreditation process. In 2000, the accreditation process improvement initiative began to implement changes to the accreditation process, including the following:

- Revising the random unannounced survey process
- Addressing staffing effectiveness in the survey process
- Revising accreditation-decision categories
- Eliminating summary scores for organizations
- Reviewing and rewriting standards
- Enhancing use of the extranet
- Conducting periodic performance review (PPR)
- Priority focus process (PFP)
- Developing a new on-site survey agenda
- Enhancing surveyor development initiatives
- Developing new accreditation decision and reporting approaches

JCAHO looks forward to the implementation in 2004 of the new accreditation process: *Shared Visions—New Pathways* (SVNP). The JCAHO mission, “to continuously improve the safety and quality of care provided to the public through the provision of health care accreditation and related services,” will not change with the introduction of SVNP, but the path JCAHO will take to achieve this mission will change.

The current survey process has allowed organizations to focus on survey preparation and organization-specific accreditation scores. Under the new accreditation process, less focus will be placed on ramp-up for survey, and instead, on continuous standards com-

pliance. Joint Commission surveyors and staff will work with health care organizations under the new model to continually improve their systems and operations, eliminating the need for “ramp-up” or survey preparation. The components of the SVNP initiative fit together to guide us toward a better accreditation process and, as a result, better health care.

The components of the SVNP initiative were developed through extensive research and testing. They use technology and processes that are common in many industries. Most accrediting bodies use some form of self-assessment, which has proven effective not only in the health care industry, but in academia as well. The priority focus process (PFP) is a decision support tool that uses data to provide a focus on specific information. This type of tool is based on technology used in many industries to help consumers make decisions based on provided information. Similarly, surveyors will use PFP data to select areas of focus during a survey, based on presurvey data that was fed into the PFP tool. The tracer methodology is a further advancement of the individual-centered evaluation approach (ICE) that the JCAHO has been using effectively for several years.

The objects of SVNP are summarized as follows:

- Shift the paradigm from survey prep to systems improvement
- Focus away from the exam and score
- Focus toward using the standards to achieve and maintain excellent operational systems
- Enhance relevance of standards and accreditation process
- Focus on safety and quality of care
- Maintain rigorous but fair evaluation
- Enhance surveyor skill and consistency
- Maximize educational benefit
- Control or lower health care organization (HCO) costs
- Improve customer service

122

Medical Equipment Management Program and ANSI/AAMI EQ56

Ethan Hertz

Duke University Health System
Durham, NC

Most clinical engineers are involved in some way with the management of medical equipment. Modern medical care relies upon a wide variety of equipment to diagnose, monitor, and treat patients. Clinical engineers are often charged with keeping that equipment in good working condition.

In the U.S., the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) accredits most hospitals. The JCAHO’s Environment of Care standards require that a hospital design and implement an equipment management program to ensure that the medical equipment used by the hospital is safe, accessible, and effective.

In general, the JCAHO standards describe the broad elements the JCAHO expects to find when reviewing an equipment management program. For the most part, JCAHO standards focus on outcomes. They describe the types of expected results, but leave the methods for reaching those results up to the hospital. It is the hospital’s responsibility to demonstrate that its actions actually meet the JCAHO’s standards.

In the early 1990s, the JCAHO made the transition from department-focused, prescriptive requirements to function-focused, outcome-oriented standards. More recently, some individuals responsible for meeting the standards expressed frustration about the general nature of the JCAHO’s requirements and asked for specific guidance. In response, the JCAHO has added explanatory materials to its accreditation manual, including sections describing the intent of the standards and examples of implementation actions taken by some hospitals to meet those standards. However, even with these improvements, some members of the clinical engineering community saw the need to develop a document to provide a more detailed set of guidelines that would help hospitals understand the elements of an equipment management program from the perspective of equipment management experts.

In 1994, the Association for the Advancement of Medical Instrumentation (AAMI) formed a committee to write such a document. The committee included hospital rep-

resentatives, equipment manufacturers, independent service organizations, the JCAHO, the American Society for Hospital Engineering, the American College of Clinical Engineering, the Society of Biomedical Equipment Technicians, the United States Food and Drug Administration, and the United States military. After several years of work, the document was approved as an AAMI recommended practice, and accepted by the American National Standards Institute (ANSI) as an American national standard. In 1999, the committee’s work was published as ANSI/AAMI EQ56: 1999, “Recommended Practice for a Medical Equipment Management Program.”

The intended audience for EQ56 is anyone working in a health care setting who is responsible for any part of an equipment management program, including hospital administrators, clinical engineers (CEs), and biomedical equipment technicians (BMETs). The EQ56 tries to complement the JCAHO standards by fleshing out some of the details that define a truly effective equipment management plan.

EQ56 Basics

The objective of an equipment management program is to effectively utilize the limited resources available to a hospital to keep its equipment functioning safely and effectively. The EQ56 is designed to provide a framework to help the hospital examine its needs and resources and balance them effectively.

Except in a few areas, EQ56, like the JCAHO standards, does not prescribe specific actions. For example, to determine how often any particular medical device should be inspected and what specific activities should be included in that inspection is left up to the

hospital. EQ56 details the considerations that should be taken into account when a hospital develops its equipment management program. The document attempts to lead each hospital to consider the most appropriate equipment management choices when designing and implementing a program for that hospital.

Every hospital is different. Hospitals support different patient populations, have different mixes of equipment, and have access to different levels of resources. Therefore, EQ56 does not mandate a single level of activity for each hospital. Instead, the philosophy of EQ56 is best summarized as: "Say what you do, and then do what you say."

Neutrality is a central feature of EQ56. The hospital as a whole is responsible for meeting EQ56's requirements, rather than just a particular department or service provider. Some hospitals meet their equipment management needs by hiring in-house personnel to monitor the condition of equipment and then perform the necessary inspections and maintenance. Other hospitals choose to contract with equipment manufacturers or independent service organizations for similar services. Still others meet their needs by mixing in-house, manufacturer and independent service organizations. Regardless of how the results are achieved, in keeping with the JCAHO focus on outcomes, EQ56 expects the hospital to take the steps necessary to ensure that its particular service arrangements meet EQ56's requirements for tracking and maintaining the hospital's equipment.

A hospital is expected to develop documents that address the elements of EQ56. Throughout EQ56's clauses are questions that a hospital should answer as it develops its equipment management plan.

EQ56 is divided into several sections, each addressing a different aspect of equipment management. Issues addressed in the document include program design, program implementation, including equipment inventory and procedure development, service agent training, acceptance testing, scheduled inspections, staffing, space, financial resources, tools, assessment and planning, equipment selection, removal from service, communication, incident investigation, and the Safe Medical Devices Act.

While this chapter describes many of the requirements of EQ56, it is not a substitute for the actual document. That publication describes the requirements of an effective equipment management program in detail and includes a discussion of the rationale for each requirement. In addition, EQ56 contains situations in which exceptions to its requirements may be appropriate. Anyone responsible for developing an equipment management program can obtain a copy of EQ56 from AAMI. The AAMI website (www.aami.org) provides specific information about ordering this publication.

Specific Requirements of EQ56

The specific requirements of EQ56 are summarized as follows, with a brief description of each of the major areas addressed.

Inclusion Criteria (4.1)

Any equipment management program must answer the fundamental question of what is and is not part of the program. Section 4.1 discusses how the hospital should determine which equipment to include in its program. Specifically, the hospital is expected to develop criteria that consider the equipment's function, physical risks, maintenance requirements, and known incident history. These criteria must be documented. The hospital is expected to examine each medical device it uses and determine whether it should be included in the inventory of managed devices based upon these criteria. The hospital is expected to document whether each new medical device has been evaluated against the program's criteria. Finally, as the hospital changes its inclusion criteria, it is expected to document these changes and the impact they will have on its program inventory.

Inventory (4.2)

The purpose of the inventory is to help the hospital schedule routine inspections for the equipment included in the maintenance program and retrieve the equipment quickly if it should be recalled. Section 4.2 discusses the actual listing of the inventory. The hospital is expected to maintain a list that shows all of the items it has chosen to include in its equipment management program. This list must be comprehensive; all equipment that meets the inclusion criteria developed in 4.1 must be listed, regardless of ownership. While most hospitals have little trouble maintaining records for the equipment owned by the hospital, documentation becomes more of a challenge when the equipment involved belongs to another party, as is the case with loaner, leased, rented, or research equipment. However, a patient should expect that any equipment used to provide hospital-related medical treatments is safe, regardless of its ownership. Most equipment must become part of the inventory, but equipment that is expected to be in the hospital for less than 15 days is an exception to this rule.

The minimum requirements for information to be included in the inventory database are specified in EQ56. These requirements include a unique identification number, the name of the equipment manufacturer, model and serial numbers, a description, the usual location, the department that owns the equipment, identification of the primary service provider, and the acceptance date. EQ56 does allow more information to be collected if the hospital finds it useful. For example, some hospitals include information such as software revision, acquisition cost, estimated useful life, and warranty expiration in their equipment inventory databases.

The JCAHO standards require that the equipment inventory be accurate. EQ56 expands on that requirement by identifying a methodology for auditing accuracy. EQ56 requires that an audit be conducted annually, based on statistical analysis. In this audit, a certain number of devices must be randomly selected, and the inventory database information about the selected devices must be compared with the actual information from the device. For example, if the equipment inventory includes between 501 and 1000 items, then 35 randomly selected pieces of equipment must be included in the audit in order to make it statistically valid. Before starting the audit, the hospital must develop a document that

establishes its standards for inventory accuracy and outlines the steps needed to bring the inventory up standards if the audit identifies a deficiency.

Finally, regardless of how the inventory is maintained, the hospital must be able to produce a written copy of the entire inventory listing upon demand. This inventory must be separate from other inventories, such as the hospital's capital asset inventory. In addition, if different service providers maintain separate inventories, all of the inventories should be readily available to combined so that the hospital or surveyor can quickly determine the overall equipment inventory.

Inspection and Repair Procedures (4.2.2)

Section 4.2.2 discusses the requirements for the procedures used to inspect and repair equipment. The hospital is required to develop or adopt procedures that describe what a technician is expected to do when inspecting a device. In addition, each inspection procedure must include an estimate of the time required to perform that procedure. This time estimate determines the adequacy of the equipment inspection and maintenance staff.

In addition to inspection procedures, the hospital is expected to develop or adopt repair procedures. These differ from inspection procedures in that inspection procedures generally provide a significant level of detail. Repair procedures, on the other hand, should include general guidelines for completing a repair and descriptions of the documentation that must be kept about a repair. The hospital's repair procedures are expected to describe how an equipment user obtains repair services and the expectations for alternate care procedures to follow when a critical medical device is not available. Finally, this section asks the hospital to develop a records retention policy for the documentation of completed inspections and repairs.

Service Agents Training (4.3)

Section 4.3 describes the training of service agents. These are the employees who perform equipment maintenance activities. These may be in-house employees, or employees of an outside service group. Regardless, it is the hospital's responsibility to assure that anyone maintaining its equipment is qualified to do so.

Generally, documentation of each service agent's training must be maintained, along with an evaluation process that determines the training needs of each agent. EQ56 recognizes that different agents will have different training needs. Employees responsible for performing equipment inspections are expected to have sufficient training to ensure that they are capable of following maintenance procedures. Other factors to consider when developing a training program include the required safety training and the experience level of each employee. Other elements include the knowledge required to advance to other positions in the organization and training related to industry certifications, such as CBET certification.

There are two quantitative requirements in this section. First, each employee should receive at least 72 hours of training over a three-year period. In addition, a new employee is expected to receive at least 36 hours of training during the first year of employment. This requirement recognizes the need to orient and train a new employee in the practices of the hospital and service organization and to introduce the procedures that the employee is expected to use during maintenance activities.

Acceptance Testing (4.4)

As new equipment arrives in the hospital, it must be acceptance tested (also referred to as an incoming inspection) to show that it is in proper working condition before it is used on patients. These requirements are discussed in section 4.4. Acceptance testing should follow procedures established by the hospital. The hospital must consider whether communication should take place between the department or service organization performing the acceptance test and other departments in the hospital. For example, the hospital may want equipment users to know that their equipment has arrived and is ready for installation. In some cases, a separate department is responsible for training equipment users, and that department must know that the equipment has arrived in order to schedule appropriate training. The hospital also might alert the accounting department, in order to release payment and/or initiate appropriate capital asset tracking.

Inspection Intervals (4.5)

Scheduled inspections should take place once the equipment has become part of the hospital's inventory. Section 4.5 addresses the requirements related to assigning and modifying inspection intervals. The hospital also should track failed inspections to justify changes in inspection intervals.

Staffing (4.6)

Staffing requirements are covered in section 4.6. Staff members must be available to perform the scheduled inspections discussed in section 4.2. In addition, the hospital should plan to have sufficient staff available to meet the workload associated with repairs. It is important to note that this requirement, like all the others in EQ56, applies to in-house departments and outside service organizations. For example, if a hospital decides to contract with an outside service provider, it must show that it has reviewed that provider's staffing plan, and determined that it will meet the hospital's anticipated needs for maintenance activities. Generally, the total time required to perform inspections based upon the number of items in the inventory and the estimated inspection procedure times determines staff adequacy. In addition, time for anticipated repairs and for support activities such as documentation and training, must be factored in.

Space (4.7)

Space is always at a premium in a hospital. Section 4.7 addresses the requirements related to space. Generally, the hospital must show it has allocated sufficient space

for work areas, storage of equipment awaiting repair, any replacement parts inventory, and documentation. In addition, the hospital must identify space in which to keep equipment that is not available for use, such as equipment awaiting acceptance tests or equipment under investigation as part of an incident. Finally, safety and sanitation issues must be considered when identifying equipment maintenance areas, meaning that hand-washing facilities are readily available, and adequate ventilation is present in the work area to quickly and safely dissipate any fumes from chemicals used during maintenance.

Financial Management (4.8)

Financial support is critical to the success of an equipment management program. In order to demonstrate adequate financial support for an equipment management program, the hospital must establish a methodology to determine the cost for services and show a budget that covers those costs.

Test Equipment (4.9)

The inspection and service of equipment requires many different types of tools. For example, many procedures require a technician to remove the equipment case in order to test internal components, a job that often requires screwdrivers and pliers. Section 4.9 discusses the availability of tools, ranging from basic hand tools to the sophisticated instruments needed to perform tests, such as checking defibrillator-output levels. In addition to the tools needed for routine work, personal protective equipment must be available. Finally, this section identifies the need for periodic recalibrations of test equipment.

The areas discussed come to mind as the day-to-day responsibilities of medical equipment management. The remainder of EQ56 concerns other components of an equipment management program that are also important but that are perhaps more global in their impact.

JCAHO (4.10)

Section 4.10 addresses the JCAHO standards for performance improvement. The hospital is expected to demonstrate its performance of scheduled equipment inspections, along with another indicator that tracks repairs. At least annually, the hospital should assess its equipment management program to determine improvements, and to plan for any upcoming environmental changes that might impact the program.

Equipment Selection (4.11)

Hospital purchases new equipment as equipment ages and new technologies become available. Section 4.11 addresses the equipment selection process, with the expectation that a hospital considers its experience with its current vendors when purchasing new equipment.

Obsolescence (4.12)

At some point, a device no longer functions. To ensure that obsolete or unsafe equipment is no longer used by the hospital, Section 4.12 discusses the development of a "removal from service policy."

Communication (4.13 and 4.14)

Effective communication is important to controlling the activities of an equipment management program. The next two sections of EQ56 deal with communication. Specifically, Section 4.13 addresses the communication between service agents and service providers; i.e., the employees who actually take care of the equipment maintenance activities and the service group or department to which they report. Service agents are expected to respond to changes within their own organizations, as well as to changes within the hospital. To help everyone keep aware of those changes, EQ56 recommends at least one staff meeting per month, at which management will inform employees of any changes. However, it is also the responsibility of employees to inform their managers of any changes they that they thing might affect the service organization's activities. The communication is expected to always be two-way.

Complementing 4.13, Section 4.14 addresses communication between the service organization and the hospital. Changes in the hospital's management, policies, or needs should be communicated to the management of the service organization so it can continue

to meet the needs of the hospital. Two major communication responsibilities of the service organization are outlined in this section: to keep the hospital informed about the inspection status of its equipment, and to let the hospital know, if any deficiencies are found that indicate a need for user training.

Incident Investigation (4.15)

Section 4.15 addresses the hospital's approach to incident investigation. EQ56 requires that a qualified person participate in an incident investigation, and the hospital should have appropriate policies to allow the investigation to take place. For example, the policies should preserve evidence and allow for sequestration of the equipment involved. They should also address when and to whom the equipment can be released in order for the investigation to proceed.

Probably most important requirements in this section are those that a hospital takes steps to learn from any incidents that occur, and makes appropriate changes to prevent similar incidents in the future. To facilitate this process, Section 4.15 requires that information about an incident be shared with the people within the organization who can make changes, such as the safety committee and risk management personnel. In addition, the hospital should review the severity of the incident and determine whether the findings related to it warrant reporting information to any outside organization, thus allowing the entire health care industry to learn from the hospital's experiences.

Safe Medical Devices Act of 1990 (4.16)

The final section of EQ56 addresses the Safe Medical Devices Act of 1990. Essentially, Section 4.16 requires that the hospital comply with its legal obligations under this federal legislation.

Exclusions

While EQ56 is fairly comprehensive, it specifically excludes activities related to user training. Many equipment management programs are, quite properly, involved in user training, but the committee found that there was not enough consistency within hospitals to include user training in the final publication. Some hospitals rely on special departments, such as nursing education, to train users. In other cases, hospitals adopt a peer-training model, where one user trains other users. In a few cases, the hospital's in-house clinical engineering department is directly responsible for user training. While the EQ56 acknowledges the importance of effective user training, the variety of models found for user training and skills assessment led to the exclusion of user training requirements from the final document.

Summary

The "Recommended Practice for a Medical Equipment Management Program" is a document that is helpful to anyone involved with a medical equipment management program. It is an American national standard, developed by a committee of equipment experts representing hospitals, manufacturers, professional organizations, JCAHO, and the federal government.

The document identifies the key elements of an equipment management program, and establishes a community standard for how these elements should be incorporated in a hospital's program.

EQ56 discusses the documentation that should support the planning and implementation that are part of an equipment management program. It discusses the key aspects of a program, including program design, equipment inclusion criteria, equipment inventory, inspection and maintenance procedures, training, resources, communications, equipment selection, and incident investigation.

Clinical Engineering Standards of Practice for Canada

Tony Easty

Head, Medical Engineering Department
The Toronto Hospital
Toronto, Ontario, Canada

William M. Gentles

BT Medical Technology Consulting
Toronto, Ontario, Canada

This chapter outlines the development process of the *Clinical Engineering Standard of Practice for Canada* and the rationale behind what was included and what was omitted. It also outlines the development of a peer review process based on the standard practice, which is meant to act as a quality improvement tool.

The practice of clinical engineering has evolved over the years as the needs of the health care systems that it serves have changed. Unlike many professions with a support role in health care, such as physiotherapists, respiratory therapists, or pathologists, the roles and responsibilities of clinical engineers have been relatively ill defined. Clinical engineering services evolved in different directions depending on the skills and interests of the staff. As the profession has matured, there is a growing consensus that a core set of activities should be included in any clinical engineering service. This chapter outlines the development of a standard of practice for clinical engineering by clinical engineering professionals in Canada.

The Canadian clinical engineering community is relatively close-knit, despite the size of the country. Most engineers are employees of hospitals or groups of hospitals, rather than private industry. This situation has evolved due to the single-payer government-funded health care system in Canada. Consequently, the high degree of information-sharing and collaboration has made the development of a standard of practice easier than it would be in a for-profit health care environment.

Identification of the Need for a Standard of Practice

The Canadian equivalent of the United States' Joint Commission on Accreditation of Healthcare Organizations (JCAHO) is the Canadian Council on Health Services Accreditation (CCHSA). Prior to 1990, the CCHSA accreditation document had a specific and comprehensive section on medical devices. This section outlined what hospitals should have in place to manage technology. It had been written with input from the Canadian Medical and Biological Engineering Society (CMBES), with a committee led by Jim McEwen.

In 1990, the CCHSA and the JCAHO shifted the focus of accreditation to a patient-centered model. The emphasis on prescriptive structural elements was reduced and replaced with an emphasis on patient outcomes and quality of care. It was left to the individual organizations to organize support services and manage technology. It was also left up to individual professions to set their own standards. This shift led to a fear that the justification for well-organized clinical engineering services would diminish.

This shift in accreditation standards caused much discussion within the clinical engineering community in the U.S. and Canada. At the Canadian Medical and Biological Engineering Conference in Vancouver in 1994, the CMBES clinical engineering special interest group agreed that clinical engineering would benefit from a published standard of practice that would provide clinical engineering departments or services across the country with a common yardstick against which they could measure themselves. At the same time, the standard should provide the basis for a peer review mechanism, which would provide stronger incentives for services to meet it. In addition, a peer review process would provide a reference point for the CCHSA, which was interested in any external reviews of services within a health care organization. This process was an important step in the development of clinical engineering as a recognized profession, since self-regulation is a cornerstone of most professions.

Development and Approval of the Canadian Standard of Practice

A committee consisting of Tony Easty and Bill Gentles was appointed the task of setting up a process for developing a standard that could be adopted by the CMBES. They recruited the assistance of Ted McLeod, a clinical engineering master's student at the

Institute of Biomaterials & Biomedical Engineering at the University of Toronto, to assist them in the project.

This group had a mandate to develop a draft standard of practice for the society. They reported to the chair of professional affairs of the society, who at that time was Gordon Campbell. They began in 1994 by investigating standards of practice in other health disciplines in Canada and around the world. They obtained and reviewed copies of standards related to social workers, psychologists, medical radiation technologists, occupational therapists, respiratory therapists, dieticians, nurses, physicians, and pathologists; two professions from which the group borrowed heavily in the development of the standard were physiotherapists and pathologists. The physiotherapists had developed standards of practice and a peer review mechanism that seemed to align well with the clinical engineers' stated mandate to define the scope and role of clinical engineering in Canadian health care organizations. The College of American Pathologists (CAP) has operated an accreditation program for laboratories for the past 35 years. JCAHO accepts the inspection results from CAP accreditation. Participating laboratories must agree to provide an inspection team equal in size and complexity to that required for its own inspection.

The next step in the development process was to write a draft in collaboration with a review committee of approximately 18 clinical engineers from across the country. This first draft was presented at the CMBES annual conference in Montreal in September 1995. A lively and extended discussion in a packed room indicated great interest within the profession, and the meeting led to numerous amendments of the draft standard.

Amended drafts were circulated to the working group in 1995 and early 1996 for fine-tuning. A polished draft was presented at the CMBES annual conference in Charlottetown, Prince Edward Island, in June 1996. After further revision, Draft Five was circulated to the full membership of the society in November 1996, requesting a vote of acceptance. An overwhelming majority of members voted in favor, and the society adopted and published the standard.

Underlying Philosophy of the Standard

Over the course of development of the standard, a fairly clear underlying philosophy evolved that dictated what should be included and what should be omitted. The first objective was to define the scope and role of clinical engineering in Canadian health care organizations. Of equal importance was the definition of standards suitable for peer review measurement and evaluation program similar to that of the College of American Pathologists.

After much debate, a consensus emerged that the standards should describe only what should be done, not who should do it or what their qualifications should be. The wide range of qualifications of people managing clinical engineering services across the country necessitated this approach. In smaller hospitals, the manager of the clinical engineering group was usually a technologist. In larger hospitals or regional services, the manager was usually an engineer. It was important to develop a standard that could be used by an organization of any size of organization and management structure.

Elements of the Standard

The standard has eight major sections, outlined as follows.

1. PREAMBLE

States the goals of the standard as follows:

- To define the scope and role of clinical engineering in Canadian health care organizations
- To define standards for measurement and evaluation

2. SERVICE MANAGEMENT

- Organization
- Personnel requirements
- Policies and procedures
- Facilities

3. Medical DEVICE TECHNOLOGY Management

- Device tracking and inventory
- Acquisition
- Unscheduled maintenance
- Scheduled maintenance.

4. TECHNOLOGY ASSESSMENTS and Planning

- Planning and pre-purchase evaluation
- Assessment of safety, efficacy and cost-effectiveness
- Long-range device planning
- Knowledge of emerging technologies.

5. RISK MANAGEMENT

- Ensure that devices conform to relevant safety standards.
- Re-use policy development
- Management of hazard alerts and recalls
- Organization of risk management program
- Incident investigation

6. QUALITY MANAGEMENT

- Identification of quality goals
- Consider customer input
- Establish a quality system structure
- Integration with the organization's quality programs
- Staff training on quality issues
- Failure analysis
- Annual internal review of quality program

7. EDUCATION

- Education of service staff
- Education of device users
- Education of clinical engineering interns and students

8. RESEARCH AND DEVELOPMENT and the MODIFICATION of medical devices

- Consider scope of involvement
- Devices are in alignment with organization mission and goals
- Participation of service staff
- Publications and presentations
- Ethics requirements of the organization
- Modification of devices
- User involvement in design and modification

Issues Left Out of the Standard

Numerous items were deliberately left out of the standard as a reflection of the realities of the profession. It was agreed that any mention of the necessary qualifications for the head of service would be left out, since it was clear that in many cases a highly skilled and experienced technologist managed a clinical engineering service. An attempt to mandate qualifications was deemed self-defeating because the standards did not have the authority of government legislation.

In Canada, engineering is a regulated profession. This means that by law, no one can work as an engineer without a license. Technicians and technologists are also regulated to a limited extent. The standards were designed to avoid any overlap with existing legislation. Since existing legislation already governed the ethical behaviour of engineers and technologists, a code of ethics was not incorporated or mentioned in the standard.

The standard mentions certification as a valid educational objective for service staff, but it does not require that any staff be certified. After much debate, certification was deemed outside the scope of a standard of practice that does not have the force of law.

Prescriptive specifications, such as number of technical staff, number of square feet, and frequency of preventive maintenance (PM) interventions, were omitted from the standard. These were seen as moving targets that would quickly make the document obsolete. Such practices would be assessed during a peer review to confirm adherence to accepted practice. The reviewers would be expected to have knowledge of the current specifications.

Development of a Peer Review Process Based on the Standard

From the outset, the standard assumed that a peer review process would be required. Peer review remains important for the following reasons:

1. It is an effective quality improvement tool.
2. It ensures that experienced professionals assess clinical engineering services.
3. It enhances the sharing of ideas in the clinical engineering community.

4. A standard that is not associated with an ongoing review process will be ignored.
5. Changes in accreditation standards mean that clinical engineering services will get less scrutiny in an accreditation survey.

Debates addressed the risks involved in subjecting an in-house service to peer review. Ill-informed administrators might use it as a way to cut service or hand clinical engineering over to an outside vendor. The counterargument accepted by the majority of CMBES members was that in times of restraint, any hospital support service might be subjected to an external review. If the profession does not have its own review process, administrators will find so-called experts outside the field to perform reviews, which will inevitably be ill informed.

Once the standard was adopted by the society, the same task force started to draft a workable peer review process that could be used by large and small services alike.

It was agreed that the development of the peer review process should go through the following stages to national implementation:

1. Definition of process
2. Create of supporting documents
3. Recruit test sites
4. Conduct pilot reviews
5. Refine of process
6. Implement nationally

In May 2001, the development had reached the implementation phase. Four pilot reviews were conducted in the spring of 2000, and all participants considered them highly successful and valuable. The process was refined and approved at the CMBES annual meeting in Halifax in October 2000.

Process Definition Document

An overview of how the peer review process should function appears in the Peer Review Process Definition document. The sections of the document are as follows:

1. Policies

- Peer review process is managed by CMBES peer review committee
- Peer review committee reports to CMBES professional affairs committee
- Peer review committee members are a mix of engineers and technologists
- Peer review committee responsibilities
 - Oversees nomination of survey team and approves composition of team
 - Defines responsibilities of survey team
 - Responsible for training surveyors
 - Reviews pre-survey questionnaire to determine if site is ready to be surveyed
 - Reviews post-survey questionnaires
 - Maintains database of peer review activities
 - Revises and updates process support documents (see below) as required
- Standards. The process is based on *Clinical Engineering Standards of Practice for Canada*
- Survey team: The process of selecting surveyors, and determining size of the survey team.
- Peer review interval: Three years between reviews

2. Peer review process

- Application for survey by a clinical engineering service
- Preparation for survey by the service
 - First step is a self-appraisal using the pre-survey questionnaire
 - Completed self-appraisal is submitted to the peer review committee with a list of proposed surveyors.
- Survey process
 - Preparation activities of peer review committee and survey team
 - Timelines for the survey process
 - Activities during the survey team visit
 - Post-visit reporting requirements
- Peer review process is self-funding
 - No survey fees
 - Surveyors pay own expenses
- Final product
 - A written report outlining strengths, weaknesses, and priorities for improvement, is sent to the device that was surveyed.

Process Support Documents

The supporting documents that make the process function smoothly are as follows:

1. Pre-survey questionnaire

- Includes a checklist based on the standards of practice, to be filled out by those being surveyed
- Requests additional information about the service, such as organizational charts and policy and procedure manuals

2. Standards of practice (document on which the survey questionnaire is based)

3. Survey questionnaire

- Checklist based on standards of practice
- Similar to pre-survey questionnaire
- Completed by surveyors

4. Surveyors' post-survey questionnaire

- Asks surveyors for suggestions on how to improve the survey process

5. Surveyee post-survey questionnaire

- Asks site that was surveyed for suggestions on how to improve the survey process
- Surveyor guidelines
- Training tool for surveyors
- Promotes a collaborative, rather than judgmental, approach

Contentious Issues—Fees and Awards

Two elements of the above-mentioned process have been the subject of considerable debate. The first is the lack of survey fees. This recommendation is based on the difficulty that smaller departments would have in securing funds. In addition, the benefit to the surveyors from conducting surveys is at least as great as the benefit to the site, given the exchange of ideas that takes place. The rule that no fees are charged will force participants to find the most economical way to conduct the surveys. For example, it prevents sites in Newfoundland, on the east coast, from seeking surveyors in British Columbia, on the west coast, due to travel costs.

The second controversial element is awards. After the four pilot surveys, the consensus of all participants was that the chief value of the process was as a quality improvement tool, with a checklist for areas of improvement from experienced outside reviewers. Hospital administrators saw the value of an award as questionable at this point in time, partly due to the lack of understanding of its significance. In addition, the absence of an award meant that the site being surveyed was not purposefully putting the best foot for-

ward and glossing over weaknesses. Without the complication of an award, both the surveyors and surveyees are working to find ways to improve the service.

Summary

This section describes the development of a standard of practice and peer review process. The changing accreditation standards were among the forces that led to the development of this standard. Another stimulus was a consensus about the essential core activities of a clinical engineering service.

The importance of associating a peer review process with a standard of practice cannot be overemphasized. One of the principal activities of a profession is self-regulation, and peer review is one form of self-regulation. In addition, any standard that is not associated with a periodic review mechanism is often ignored.

The development of the documents and processes described in this chapter is an important step in the maturity of clinical engineering as a profession.

Regulations and the Law

Michael Cheng

Health Technology Management
Ottawa, Ontario, Canada

Webster's International Dictionary defines "regulate" as "to govern or direct according to rule." Regulations are mandatory, but the mandate might or might not be legally based. When the mandate comes from the government, regulations are based on laws established by the government. This chapter describes, in the North American context, the relationship between regulations and the law.

Different countries and different levels of governments have different legislative systems and procedures. In the U.S. and Canada, medical devices are regulated by the federal governments, where the first-level laws, called "acts" or "statutes," are established by the Congress (in the U.S.) or the Federal Parliament (Canada). Acts and statutes are usually brief statements covering a wide scope of applications. Medical device regulations derive from the legal power of relevant acts and statutes, and the regulations provide specific and detailed statements. For example, a statement such as "No person shall sell unsafe or ineffective medical devices" in an act or a statute can lead to a volume of medical device regulations specifying requirements for product approval, vendor registration, and after-sales obligations.

Guidance documents often are written after the regulations or standards are established. They normally use plain language to provide interpretations of the regulations and standards, usually with added specific details. See, for example, Chapter 122 as a guideline. Figure 124-1 shows the relationships and differences among acts/statutes, regulations, standards and guidelines relevant to medical devices.

Note that Governments normally consult all stakeholders, but that they do not necessarily need to seek consensus as in most international standards (Chapter 117). A voluntary standard can be recognized fully or partially by a government as part of regulatory requirements by a government.

Regulating Medical Devices

Compared with drug regulations, medical device regulations are relatively new. Canada and the United States started to regulate medical devices in the mid 1970s (see Chapter

126). The first harmonized European Union Directive on Active Implantable Medical Devices came into force in 1993. One can see that this field is evolving, particularly to keep pace with the rapid technological innovations. Because of the explosive growth in medical devices, estimated by the U.S. Food and Drug Administration Center for Devices and Radiological Health (USA FDA CDRH) in June of 2001 to be 10,000 new devices per year, and the concerns for safety, effectiveness, quality, and the impact on health care costs, many other countries are only beginning to set up the regulatory or monitoring programs for medical devices.

Different countries have been following different standards and regulatory systems. This chapter describes the general concepts and approach used in the U.S., the European Union, and Canada. Detailed descriptions of the U.S. system and the European Union system are found elsewhere in this handbook (see Chapters 125 and 126).

Glossary

In regulations, terms are legally binding and therefore have restricted meanings. For example, *manufacturer*, *distributor*, *vendors*, and *retailers* all have precise definitions in regulations; and their definitions vary in the regulations of different countries. A regulation normally has an accompanying list of definitions of terms used. This chapter provides an integrated description of three different medical device regulations. It is written to promote a *general understanding* of medical device regulations; therefore, the words used are nonbinding but carry general meanings. The meaning of several terms that could cause confusion are described below for the purpose of this chapter

Manufacturer Any person who makes medical devices

Vendor Any person who sells medical devices. This person could be a manufacturer, an importer, a distributor, a wholesaler, or a retailer.

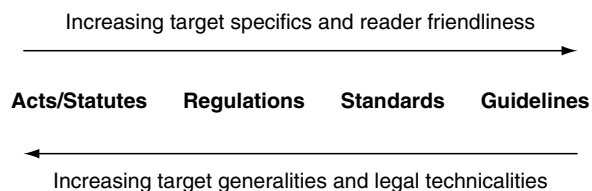

Figure 124-1 Relationships among acts/statutes, regulations, standards, and guidelines relevant to medical devices.

Person Includes an establishment (in that case, person in charge or person responsible).

Effectiveness A device is clinically effective when it produces the effect intended by the manufacturer relative to the medical conditions. For example, if a device is intended for pain relief, one would expect the device to actually relieve pain and would expect the manufacturer to possess objective evidence, such as clinical test results, that the device in fact does relieve pain. Effectiveness can be thought of as efficacy in the real-world clinical environment.

Efficacy Not used in this guideline; generally means effectiveness under an ideal, controlled setting.

Performance Means technical performance plus effectiveness.

Risk Management in Medical Device Regulations

Most of the new medical device regulations follow the risk-management philosophy. All devices carry a certain degree of risk that could cause problems under specific circumstances. Many medical device problems cannot be known until extensive market experience is gained. For example, an implantable device may fail in a manner that was not predictable at the time of implantation; the failure could be caused by conditions that are unique to certain patients. For nonimplant devices, component failure can occur in an unpredictable, random manner. One practical approach to device safety is to estimate the potential of a device becoming a hazard that could cause safety problems. This approach is often referred to as the *risk-assessment* of devices.

Hazard means a potential for an adverse event, a source of danger. *Risk* is a measure of the combination of (1) the hazard; (2) the likelihood of occurrence of the adverse event; and (3) the severity or overall impact. *Risk assessment* begins with *risk analysis* to identify all possible hazards, followed by *risk evaluation* to estimate the risk of each hazard. In general, risk assessment is based on experience, evidence, computation, or simply guesswork. Risk assessment is complex; it is influenced largely by personal perception and other factors, such as cultural background, economic conditions, and political climates. This field of knowledge is still developing.

In practice, the risk assessment of medical devices is based on the experience of health care professionals and safety-design engineering. In the United States, the government risk assessment of medical devices is based mainly on recommendations from members of 16 medical-specialty classification panels. Devices are categorized into three classes. In the European Union and Canada, the classification schemes for medical devices are predominantly rule based. These rules categorize medical devices according to their perceived potential hazard factors. Canada assigns four classes of devices. The European Union assigns three classes, with class II divided into IIa and IIb (effectively, thus, four classes). The Global Harmonization Task Force (GHTF) (see below) is proposing a harmonized scheme for Medical Devices Classification (see www.GHTF.org document SG1/N015R14).

In general, potential hazard areas that need to be considered for device classification include the degree of invasiveness, the duration of contact, the body system affected, and local-versus-systemic effects. Invasive devices are usually considered to have higher potential hazards than equivalent noninvasive devices (e.g., blood pressure monitors). Similarly, devices that have longer duration of contact, devices affecting vital organs (such as the heart or the great arteries), and devices with systemic effects are assigned higher potentials of hazard or risk classes. The degree of regulation imposed on any device is proportional to its potential hazard. This approach is known as *risk management*.

Risk management should extend throughout the life span of medical devices and it requires the co-operations from all stakeholders: manufacturer, government, vendors, users and the public (Cheng, 2003).

Critical Elements for Regulatory Attention

The critical factors that affect safety and effectiveness of a medical device and ways that regulatory authorities control these elements through different stages are identified here. The common regulatory terms *pre-market* and *post-market* will be introduced and later illustrated with the device life span diagram (Figure 124-4). The term *on-market* is not an official regulatory term but is introduced here to provide a logical understanding of the regulatory mechanism.

The safety and effectiveness of medical devices depend on the two intrinsic critical elements of *product* and *use* as seen in Figure 124-2. Governments use *pre-market review* to control the product and *post-market surveillance/vigilance* to ensure that medical devices in use continue to be safe and effective.

Representation of the product to the user is the important third element (Figure 124-3) and is controlled through labeling (during the pre-market stage) and advertisement

(during the on-market stage). A powerful component of product representation, however, verbal presentation by the vendors, is difficult to document and control. Here, user and public education is essential to guard against misrepresentation. Here, the clinical engineer can play an important role.

Stages of Regulatory Control

During the life span of a medical device, these three critical elements are affected by regulatory control (Cheng, 2003) illustrated in Figure 124-4.

These phases of activities are simplified for the ease of understanding the regulatory system. For example, the development phase may include pro-type testing and clinical trials, and in practice, these phases may overlap and interact. The terms *pre-market* and *post-market* cover different phases and activities in different countries. Placing on-market is introduced in this guide for easy overall understanding.

- *Pre-market control* is performed on the device to ensure that the product complies with acceptance criteria before entering the market.
- *Establishment (company) control*, in effect, imposes on the vendor the obligations of post-market surveillance and provides the government with records for tracking purposes.
- *Advertising control* is maintained to prevent misleading or fraudulent claims by unformed or unethical merchants.
- *Post-market surveillance/vigilance* includes the maintenance of official and systematic procedures and records for device safety and performance throughout its useful life.

Regulatory Tools and Requirements

The tools and requirements used at these stages in the medical device regulatory systems of Canada, the European Union, and the U.S. are described and summarized in Table 124-1.

Pre-Market Review

Although different authorities have different systems of pre-market review, they all use the risk-management philosophy. All medical devices must satisfy safety and performance, quality-system (some low-risk devices may be exempted), and labeling requirements. However, the degree of regulatory scrutiny increases with the potential risks of the medical devices. This approach is demonstrated by using the risk-based device-classification system (SG1-N015R14) proposed by the Global Harmonization Task Force (described below in this chapter).

In Canada, devices of classes III and IV are subject to in-depth regulatory scrutiny, while class II devices require only the manufacturer's declaration of device safety and effectiveness before sale. Class I devices are exempted from any pre-market submission, but they still must satisfy the safety, effectiveness, and labelling requirements.

In the European system, manufacturers of devices of classes II and III, as well as devices of class I with either measuring function or sterile requirements, must submit to the regulator (i.e., the competent authority): (1) a Declaration of Conformity to the appropriate EC Directives; and (2) the conformity-assessment procedure followed. In addition, for higher-risk class devices that require design examination or type examination, the

Figure 124-2 Product and use: Two critical elements.

Figure 124-3 Product representation: Third critical element.

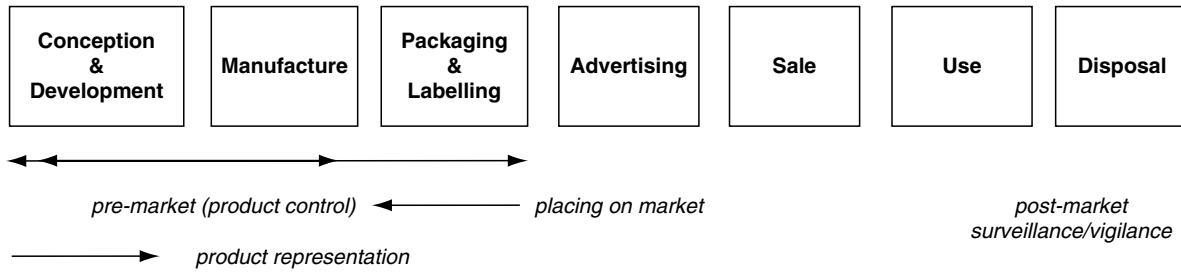

Figure 124-4 Common stages of government control.

corresponding EC-certificates issued by a Notified Body must be submitted to the competent authority. Other medical devices of class I are exempted from pre-market submissions, although they must follow labelling requirements and the essential principles of safety and performance in their design and construction.

In the United States, most Class III and new devices that cannot be found to be substantially equivalent to a legally marketed product that does not require an approved pre-market approval (PMA) application require clearance through the PMA or Product Development Protocol (PDP) process. Most class II, and some class I, devices require pre-market entry notification under paragraph 510(k) of the Medical Devices Act of 1976. A 510(k) submission to the FDA comprises an information package that is subject to less-stringent review than the PMA process. Most class I, and some class II, (low-risk) devices are exempted from 510(k) submissions before sale but are still subject to general control requirements. The 510(k) submission is a presentation of the proposed medical device that is intended to show how it is substantially equivalent to a medical device that is already on the U.S. market (Winston, 2003).

Different authorities acknowledge product clearance for the market in different ways. In Canada, it is the Device License given by the Therapeutic Products Directorate (TPD). In the EU, after receiving the EC certificate for a notified body, the CE mark is placed by the manufacturer on or with the device. In the United States, the manufacturer of the device receives a 510(k) Marketing Clearance or Approval Letter (PMA) from the FDA.

Vendor Establishment Control

Vendor information allows the government to track vendors of medical devices in the country. In Canada, any individual or company wishing to sell medical devices must apply for permission to obtain an establishment license. The EU requires that a responsible person from the vendor establishment with a physical address in Europe be registered. In the United States, the establishment (i.e., manufacturer, initial importer, specifications developer, contract sterilizer, repackager and/or relabeller) must be registered with the FDA. With all three authorities, the licensing or registration process also imposes an obligation on the vendor for post-market surveillance/duties.

Advertising Control

Advertising control is an important tool to ensure that the public is protected from misleading and fraudulent claims put forth by unethical or uninformed merchants.

Post-Market Surveillance/Vigilance

The continued assessment of safety and effectiveness of medical devices in use is as important as pre-market scrutiny (see Chapter 139). The proof of a medical device is in the way it stands up to the conditions of use. No amount of rigor in any pre-marketing review process can predict all possible device failures or problems arising from device misuse. It is through actual use that unforeseen problems related to safety and effectiveness can occur.

For some devices, post-market surveillance serves to complement pre-market data. The FDA has issued the following statement:

“Pre-market testing cannot address all devices-related concerns. While post-market surveillance will not be used in lieu of adequate pre-market testing, post-market surveil-

lance can serve to complement pre-market data. Certain issues that arise during pre-market evaluation of a device may be more appropriately addressed through data collection in the post-market period rather than prior to approval/clearance for marketing. FDA will consider the potential to collect post-market surveillance data to allow more rapid progress to market.”

Post-market vigilance generally includes a system for registering and investigating adverse incidents relating to the use of a device and for requiring the manufacturer to recall or modify a defective device. All three authorities have mandatory requirements for vendors and manufacturers to report all device-related incidents that have resulted, or that could result, in serious injury or death. In the U.S. and some EU member states, mandatory problem-reporting is extended to users.

Quality System Requirements

A quality system is defined as the organizational structure, responsibilities, procedures, processes, and resources needed to implement quality management. A closely related term is *Good Manufacturing Practices* (see Chapter 126).

The international quality system standards for medical devices are *ISO13485:1996* and *ISO13488:1996*. *ISO13485:1996* includes all of the elements of *ISO9001:1994* plus a set of minimum supplementary requirements for medical devices (Simmons, 2003). *ISO13488:1996* is the same as *ISO13485:1994* without the design control requirements. A standard alone *ISO13485:2003* is being developed to become the new international quality standard for medical devices.

Regulatory requirements for quality systems may cover the methods, facilities, and controls used by the manufacturer in the design, manufacture, packaging, labelling, storage, installation, and servicing, and post-market of medical devices. Therefore, the influences of quality system requirements can extend throughout all phases in the life span of medical devices. Applicable requirements depend upon the risk class of the device and on the regulatory system of the country. Design control is normally not required for regulatory scrutiny in medium- to low-risk class devices.

When applied to the manufacturing process, quality-system requirements impose strict quality control assurance on every aspect of production. The result is a tightly controlled manufacturing system, commonly known as *Good Manufacturing Practices* (GMPs), which reduces the chance of nonconforming products. This practice ensures consistency in the quality of the products and provides the basis for a greater reliability on device safety and performance. Elements of the quality system are periodically subject to audits, management review, and corrective or preventive actions that will maintain the quality of the product. The continuous monitoring and corrective action requirements are interrelated to post-market surveillance described above.

The key advantage regarding quality systems is that they represent a preventive approach to ensuring medical device quality versus the previous reactive approach by inspection and rejection at the end of the manufacturing line. Prevention has been proven to be more efficient and cost-effective in controlling processes and in maintaining medical device quality.

Because the majority of medical devices are in the medium- to low-risk classes, their compliance to regulations often depends upon the declarations of manufacturers, and therefore the question of quality assurance naturally arises. This is why it is important for manufacturers to conform with quality system standards. Conformity with quality-system standards is subject to periodic audit by government or third party agencies.

Table 124-1 Tools and General Requirements of Three Different Authorities

Country	Pre-market	Placing on-market	Post-market
	Product control Tools for acknowledging product cleared for the market	Medical device establishment control	Advertising control
			Vendor after-sale obligations Examples of common requirements
Canada	Device license	Establishment license	Generally, prohibition of advertisement before a device is cleared to enter the market. Prohibition of any misleading or fraudulent advertisement
European Union	Compliance label (the CE mark)	Responsible person registration	<ul style="list-style-type: none"> ● Problem reporting ● Implant registration ● distribution records ● recall procedure ● complaint handling
United States	Approval Letter (PMA) or Marketing Clearance (510k)	Establishment registration	

Table 124-2 Standards used by Canada, the EU, the U.S

Country	Standards/regulations	Conformity assessment
Canada	ISO13485, ISO13488	Third party
European Union	EN46001* or ISO13485 EN46002* or ISO13488	Third party
United States	EN46001, EN46002 QS (21 CFR part 820)	Government

Table 124-2 shows the standards used by the three authorities. The applicable standard is determined by the risk class of the device.

The Global Harmonization Task Force (GHTF)

The purpose of the Global Harmonization Task Force, established in 1993, is to encourage convergence in requirements and regulatory practices related to ensuring the safety, effectiveness, performance and quality of medical devices, promoting technological innovation and facilitating international trade. The primary way in which this is accomplished is via the publication and dissemination of harmonized guidance documents on basic regulatory practices. These documents, developed by study groups formed by experts from different countries, can then be adopted and implemented by member national regulatory authorities.

The founding members of the GHTF are Australia, Canada, Japan, the European Union, and the United States. Technical committee members include representatives from national medical device regulatory authorities and the regulated industry. The tasks of the four study groups are as follows (Cheng, 2002):

Group 1 has been charged with comparing operational medical device regulatory systems around the world and from that comparison, isolating the elements and principles that are suitable for harmonization and those that may present obstacles to uniform regulations. In addition, the group is also responsible for developing a standardized format for pre-market submissions and harmonized product-labelling requirements.

Group 2 is charged with the task of reviewing current adverse-event reporting, post-market surveillance and other forms of vigilance for medical devices and performing an analysis of different requirements among countries with developed device regulatory systems with a view to harmonizing data collection and reporting systems.

Group 3 is responsible for the task of examining existing quality-system requirements in countries having developed device regulatory systems and identifying areas suitable for harmonization.

Group 4 has been charged with the task of examining quality system auditing practices (initially among the founding members of the GHTF) and developing guidance documents laying harmonized principles for the medical device auditing process.

Guidance documents developed by these groups can be found at www.ghtf.org

Post-Market Surveillance/Vigilance on Medical Devices

No amount of scrutiny in any pre-marketing review can predict all possible device failures. The continued assessment of medical devices in use is as important as product control. Post-market surveillance and vigilance has a vital role in ensuring the safety and effectiveness of medical devices. The clinical engineer, with technical knowledge and direct user experience, is in a unique position in this vital role (Chapter 139).

Clinical engineers are urged to play an active role in post-market surveillance/vigilance on medical devices and report problems or potential problems to manufacturers and regulatory authorities. However, problem reporting in medical devices has become a controversial issue.

There seems to be a fear that information in medical device problem reporting can become a personal legal liability if it turns out that the problem was actually caused by incorrect use of the device. Therefore, there is a general reluctance to report problems associated with the use of medical devices, even though such reporting is mandatory by law in the United States and some countries in Europe. Regulatory authorities in Europe and North America are experiencing a lack of co-operation from device users.

The clinical engineer is in a position to bring a solution to this dilemma. The job description of a clinical engineer normally would include responsibilities such as technology assessment, selection, acquisition, installation, maintenance, and consultation for hospital staff on safe and effective use of medical equipment. Thus, if a problem or accident associated with medical devices occurs, it would be the duty of the clinical engineer to participate in the investigation and to distinguish between a device problem or a use error. If it is a use error, it is the clinical engineer's duty to inform or instruct the user. If it is a device problem, there should be no hesitation to report to the manufacturer and the regulator. Frequently, use error can be prevented or minimized by design, using human factors engineering principles (Chapter 83) (see www.fda.gov/cdrh/humfac/1497.html). Therefore, unless it is clearly a user blunder, a use error should be followed up with an investigation for possible corrective actions by design.

European Union Medical Device Directives and Vigilance System

Nicolas Pallikarakis

Department of Medical Physics
University of Patras
Patras, Greece

Over the past two decades, an explosion of new technologies and applications has occurred in medicine, opening up amazing possibilities for diagnosis and therapy, but also raising questions of appropriateness, safety, and effectiveness (van Gruting, 1994). The activity and accelerated development in this field are often based on an uncontrolled spread and use of medical technology, as well as a noncritical acceptance of innovations. Additionally, the rising cost of health care, due in part to new technology, is a pressing issue for many governments. This situation is expected to continue, and by the year 2010, advances in biosensors, molecular and cellular engineering, and artificial organs will change the shape of health care, as will developments in more traditional areas such as signal processing, imaging modalities, and the application of telematics. The increasing cost and sophistication of biomedical technology inevitably leads to a greater need for regulation and risk monitoring. Patient and user protection should not be compromised, but neither should progress be inhibited.

The global market for medical technology products (excluding pharmaceuticals) was estimated at about \$120 billion in 2000, with Europe sharing more than one-fourth of this world market (Bethune, 1995; Mattox, 1995; Jennett, 1992). However, fragmentation of the European market due to the inconsistencies in national regulations did not allow European manufacturers to take full advantage of this opportunity. In order to remove these internal barriers and to facilitate the free movement of goods, the European Union (EU) has adopted the “New Approach” on technical harmonization.

Under this “New Approach,” the Commission of the European Communities is working on a harmonized, community-wide legislation, which is addressed in the medical device sector by three directives: the Active Implantable Medical Device Directive (AIMD), the Medical Device Directive (AIMD), the Medical Device Directive (MD), and the In Vitro Diagnostics Directive (IVDs). The EU medical device legislation covers a large range of products. Therefore, it must address a range of risks associated with medical devices. The legislation relates to such items as electromedical equipment, surgical instruments, implants, single-use products, reagents for in vitro diagnosis, and laboratory equipment for clinical laboratories, all of which are covered by the term *medical device*. The relevant EU directives govern the placement on the market of products not only within the 15 member states of the European Union but, in practice, the whole European economic area, including Norway, Iceland, and other associated countries.

The “New Approach” and the “Essential Requirements”

The ultimate aim of the harmonization process was to introduce a set of common rules throughout the EU under which medical devices would be sold and used, thus creating the right conditions for a single market. This policy influences the European medical device manufacturers or their authorized representatives by allowing the free movement of products across national barriers. Most of these barriers existed as a result of national laws and regulations concerning the safety of products. In order to lift these barriers, the European Community introduced the directives, a set of community legal acts enacted by the Council of Ministers that oblige member states to harmonize their national regulations and administrative measures in response.

Under the “New Approach” scheme for the implementation of these directives, each member state must nominate competent authorities (CAs), which in turn, designate notified bodies (NBs). The “New Approach is as follows:”

- Directives should contain essential requirements (ERs) with which products must comply.
- Detailed technical provisions will be contained in the standards adopted by the European Committee for Standardization (CEN), online at www.cenorm.be, and the European Committee for Electrotechnical Standardization (CENELEC), online at www.cenelec.org.
- Standards are voluntary, but a product that conforms to them is presumed to comply with the corresponding ERs.
- A product that complies with the requirements of a directive is in free circulation, i.e., authorities of a member state may not stop its entry into the country under normal circumstances.

All medical devices must bear the CE-mark to be placed on the EU market. This mark is also important in the context of mutual recognition. Mutual recognition means that all 15 member states of the European Union as well as those members of the European Free Trade Association (EFTA), Iceland, Norway, Liechtenstein, and Switzerland, must accept the products into their markets and will be required to allow CE-marked products to circulate freely throughout these markets.

The general rule is that medical devices may only be placed on the market and put into service if they do not compromise the safety and health of patients, users, and third persons. According to this rule, the manufacturer must adhere to the following:

- Eliminate or reduce the risks associated with the use of the device.
- Provide other appropriate protection mechanisms and measures when some risks cannot be eliminated.

Risks addressed in specific requirements relate to chemical, physical, mechanical, and microbiological properties, as well as biocompatibility or emission of radiation. Special emphasis is placed on the information and labeling provided with a device. If residual risks exist in spite of the previously mentioned measures, patients and users shall be informed through the label and instructions accompanying the device.

It is obvious that medical device regulation requires the manufacturer to perform a risk analysis. In general, a risk that may be associated with the use of the device should be acceptable when compared to the benefit to the patient. The manufacturer must document the risk analysis and the results.

In practice, the manufacturer must demonstrate that the product complies with the ERs. A product that complies with the ERs and has followed conformity-assessment procedures is marked with a CE mark, which is its passport for free circulation throughout the European Union.

Medical Devices Directives

One of the first fields of application of the “New Approach” is medical technology, including three separate directives: Active Implantable Medical Devices, Medical Devices, and In Vitro Diagnostics.

The first directive on Active Implantable Medical Devices (AIMD) was adopted in 1990 and appeared as national legislation in 1993 (CD, 1990). The AIMD directive applies to a small number of devices that are partially or totally implanted in the human body and rely on a power source (i.e., infusion pumps, pacemakers, implantable drug pumps, neurostimulators, cochlea implants). The directive contains essential safety requirements including sterility, patient protection, or electrical hazards. The technical details are included in the harmonized European standards published by the CEN and CENELEC.

The European parliament approved the second directive on Medical Devices (MD) in 1993 (CD, 1993). The MD directive became effective in January 1995 and had a transition period until June 1998. At that time, the CE mark became mandatory. It is estimated that this directive covers approximately 80% of the medical devices currently available. The MD directive contains the essential requirements for safety and includes a set of rules for the division of the medical devices in four classes (I, IIa, IIb, and III) as along with the conformity-assessment procedures specific to each class.

The third directive relates to In Vitro Diagnostics (IVDs), intended for in vitro analysis of human samples. Implementation of this directive marks the first European regulation of reagents, as well as equipment, intended for in vitro diagnosis. The IVDs directive was adopted in 1998 and became applicable by the end of the year 2003.

The cornerstone of all three medical devices directives is the common definition of “medical device.” A medical device, according to Article 1 § 2a of the medical device directive 93/42/EEC (CE, 1993) is defined as follows:

“A medical device means any instrument, apparatus, appliance, material, or other article, whether used alone or in combination, including the software necessary for its proper application intended by the manufacturer to be used by human beings for the purposes of:

- Diagnosis, prevention, monitoring, treatment, or alleviation of disease
- Diagnosis, monitoring, treatment, alleviation of or compensation for an injury or handicap
- Investigation, replacement, or modification of the anatomy or of a physiological process
- Control of conception

A medical device does not achieve its principal intended action in or on the human body by pharmacological, immunological, or metabolic means, but it may be assisted in its function by such means.”

Medical devices are articles with medical purpose that is determined by the manufacturers. The manufacturer determines the specific medical purpose of a given device through the label, instructions for use, and promotional material related to it. The medical purpose generally relates to finished products regardless of whether they will be used alone or in combination with other products.

The protection ensured by the directives is valid for products having a stage of manufacture in which they are supplied to the final users. The medical purpose may be achieved either by using a product alone or by using a medical device in combination with other medical devices or other products (e.g., infusion pump used together with necessary tubing and needle). Therefore, the manufacturer may place a product on the market as a complete system, or it may follow the requirements of the directive for different subsets of a system, which can be placed on the market as medical devices in their own right.

Harmonized Standards and the Conformity-Assessment Procedures

European standards are adopted by the CEN and CENELEC and remain voluntary. Therefore, the manufacturer is free to apply relevant European standards or to fulfill appropriate legal requirements by other means. However, the adherence to relevant European standards brings an important advantage to the manufacturer: certification bodies and competent authorities are, in accordance with the directives, obliged to presume compliance with the directives, as far as the manufacturer has met the relevant requirements of the European standards (Article 5 AIMD MDD). Therefore, adherence to the relevant European standards provides a presumption of conformity with regard to legal requirements. Hundreds of European standards have been reviewed by CEN and CENELEC. The European Commission so far has published references of approximately 40 European standards in the official journal. Relevant standards that were published in the official journal have obtained a harmonized status and compliance with them creates the presumption of conformity.

The fulfillment of essential requirements and of requirements relating to the design and manufacture of medical devices must be established through the “conformity assessment procedures.” The manufacturer that places the medical devices on the market must conduct the conformity assessment procedure in accordance with the directives. By affixing a CE mark to each medical device, manufacturers confirm that they have met all requirements of the directive and that they have correctly followed conformity-assessment procedures.

The details of conformity assessment procedures were adopted in 1990 and reconfirmed in 1993 by the Council of Ministers, who established eight typical procedural modules for conducting conformity assessment. These modules have been used in different EC directives governing machinery, personal protective equipment, telecommunication equipment, and pressure vessels. The use of conformity-assessment modules allows for a graduated approach to determine how much an independent certification body should intervene in a conformity assessment procedure. According to the MDD, medical devices are classified in relation to the potential hazards associated with their use. Depending on the class assigned to each device, the corresponding conformity-assessment module(s) vary.

Classification

The classification concept is based on a general risk-analysis approach that estimates potential hazards related to the use of the device under normal conditions or during failures. The classification criteria consider whether a device comes into contact with the human body, whether it is invasive, duration of use, whether it is in contact with vital organs, and whether it is activated by an energy source. According to this system, medical devices are placed in one of four classes as follows:

- Class I: Lowest level/responsibility for compliance under the manufacturer
- Class IIa: Mainly control of production
- Class IIb: Both design and production control
- Class III: Highest level/pre market approval

Since the adoption of council directive 93/42/EEC (CD, 1993), the responsibility of classification of medical devices rests with the manufacturers, who must group their products into the previously mentioned four classes in accordance with rules stated in annex IX of the MDD. The Commission of the European Union has issued guidelines for the classification of medical devices into one of the four risk classes using a decision tree.

The rules are based on criteria related to duration of contact between the device and the patient, the degree of invasiveness, and the anatomy affected by the use of the device. The duration of use is divided into three periods: transient use (less than 1 hour), short term use (from 1 hour to 30 days), and long-term use (more than 30 days). A medical device is classified as invasive if it penetrates inside the body, either through the surface of the body or through a body orifice. For the noninvasive devices, contact with blood is an important classification criterion. Modification of the biological or chemical composition

of blood increases the risk associated with a device. Active medical devices are defined as those that are driven by electrical energy and differentiated in terms of the amount of energy that they exchange with the body.

According to the MDD and the guidelines, the classification rules apply accordance with the intended use of the device, not its technical characteristics. It is possible that two manufacturers would produce similar devices and assign them two different uses. Therefore, the intended, not accidental, use of a device factors into the classification of it. If a user uses a device in a manner not intended by the manufacturer, he or she does so under his or her own responsibility and does not change the class assigned for the conformity-assessment procedure.

Whenever there is a doubt as to classification based on the MDD, the manufacturer should ask an NB. If the manufacturer and the NB responsible for the conformity-assessment dispute the classification, the manufacturer should refer the matter to the competent authority, which decides the classification according to Article 9 of the directive. In addition, the directive states that the medical device committee is the final decision-maker in an extreme case.

Conformity assessment procedures, as previously mentioned, are the procedures that must be completed by a manufacturer before the CE mark can be placed on a product and a product placed on the market. It is not feasible to subject all medical devices to the most rigorous conformity-assessment procedures available. A graduated system of control is more appropriate, and a medical device classification system serves to channel medical devices into the proper conformity-assessment route.

For class I devices (simple dressings, corrective glasses, operating tables, and wheelchairs), the manufacturers are entirely responsible for conformity assessment. The manufacturers must ensure that devices comply with ERs using risk analysis to establish whether any risks present are acceptable. For class I products, the manufacturers must maintain technical documentation and create a declaration of conformity—available to CAs upon request—before placing the device on the market.

In the case of class IIa products (syringes, contact lenses, dental filling materials, and hearing aids), the manufacturer is responsible for the conformity assessment during the design of the devices, but an independent certification body must approve the products during the manufacturing stage. Class IIb products (e.g., implants, intraocular lenses, X-ray equipment, anesthesia machines, ventilators, and high-frequency surgical equipment) and class III (heart valves, resorbable implants, and medicated devices) are subjected to certification by an NB at the design and the manufacturing stages.

For class IIa, IIb and III devices when a third party intervention is required, the manufacturer may choose between at least two applicable procedures: the certification of products or the certification of the manufacturing system. In the latter case, the continuous maintenance of the manufacturer’s quality system is subject to a third-party certification by an NB. In this context, compliance with European standards (series EN/ISO 29000 in conjunction with EN 46000) facilitates the establishment of conformity.

Nomenclature Issues

Differences in the nomenclature and codification systems for medical devices, as well as nonuniform terminology applied in different countries, are some of the problems that should be resolved in order to effectively exchange information about medical devices (CEC, 1994). An agreed-upon nomenclature system to identify and describe medical device terms would facilitate data exchange across Europe and encourage implementation of the MDDs. The two most well-established systems worldwide were developed by U.S. Food and Drug Administration, online at www.fda.gov and ECRI, online at www.ecri.org. In addition, many countries in Europe have developed their own systems, which are in use at national or regional levels.

Standardization of medical device nomenclature in Europe will resolve problems with the existing systems. In order to meet this goal, standardization procedures have been initiated, and a number of working groups are active in CEN and CENELEC. The initiative CEN/TC 257/SC1, known as “Coding Systems and Nomenclature for Medical Devices,” was formed to produce a European nomenclature system. Following a request by the Commission of the European Union, the technical committee prepared European standards known as “Nomenclature: Recommendations for an Interim System and Rules for a Future System.” The same working group prepared a report on “Identification, coding, nomenclature, and regulatory data sets for medical devices,” which set the stage to elaborate on medical device standards (CEC, 1994). Device types will be identified by both the device name and manufacturer name. The Global Medical Device Nomenclature (GMDN) system follows a three-level hierarchical structure as shown in Table 125-1. The levels that can be used for administration, regulation, purchasing, aggregation, and quality assurance (QA) purposes are as follows:

- Device category (top level). This level contains 12 categories, with the potential to add more. The categories are divided on the basis of knowledge sets or professional disciplines and are as follows: active implantable devices, anesthetic/respiratory devices, dental devices, electro-medical/mechanical devices, hospital hardware, in vitro diagnostics, nonactive implantable devices, ophthalmic and optical devices, reusable surgical devices, single use devices, technical aids for disabled persons, and X-ray and imaging devices. These device categories facilitate the management of the nomenclature system.
- Generic device group (middle level). The generic device group contains sets of devices with the same or similar intended uses or common technologies, features, or functions. This level contains approximately 13,000 terms divided in three categories: preferred terms, templates, and synonyms.
- Device type (lower level). This level identifies the particular make and model of medical device and contains several hundred thousand items.

The commission will appoint a management agency in order to administer and maintain the GMDN system and promote international standardization. The Universal Medical

Table 125-1 General structure of the CEN medical device nomenclature system

Approx. Number of Terms	Structure
1020	Device category
<10,000	Generic device group
>500,000	Device type

Device Nomenclature System (UMDNS) developed and maintained by ECRI will continue to be used until the new system becomes an EN/ISO standard.

European Medical Devices Vigilance System

One of the most important tasks under the “New Approach” is the implementation of vigilance procedures concerning medical devices. The current regulations concentrate primarily on pre-marketing requirements but do not always ensure that the products will be safe or effective during use. From the perspective of the health care facility, a medical device should be subject to continuous monitoring and quality control of its functional status in the postmarketing life cycle whenever appropriate. In addition, the responsibility of the manufacturers should not stop when the device is put on the market. They should encourage the correct application of their products through appropriate guidance or user training, and monitor devices to ensure that they are performing according to their specifications.

Users can report unexpected adverse effects or research any deviation of the device’s expected performance by going back to the manufacturers (post-market surveillance) or to the competent authorities by means of a user reporting system* (Figure 125-1). Post-market surveillance is extremely important to the manufacturer, and feedback from users helps to improve reliability (Donawa, 1994). The EU directives contain some provisions regarding post-market surveillance. The obligations rest especially with manufacturers, who should institute and update a post-market surveillance system including incident reporting and recalls. The AIMD directive contains requirements for reporting device incidents. Instead of the term post-market surveillance system, the MD directives call for “a systematic procedure to review experience gained from devices in the post-production phase and to implement appropriate corrective action,” with which manufacturers must comply (see Chapter 139).

Even if the manufacturer is assigned with follow-up, maintenance remains the responsibility of health care facilities and professionals. The health care facility should make the necessary arrangements to ensure that devices are properly maintained and used. Member states are responsible for introducing appropriate measures in the framework of prevailing quality assurance that meet the user’s safety requirements.

According to the MDD, every competent authority in the European Union must implement a user-reporting system to investigate adverse incidents involving medical devices and to take appropriate measures to prevent recurrence. In addition, manufacturers are legally obliged to report any serious incidents, deaths, or severe injuries involving devices they produce and sell. Based on these requirements, the commission has prepared an adverse-incident notification and evaluation system in the form of the medical devices vigilance system guidelines (CEC, 1993). The aims of the guidelines are as follows:

- To prevent the reoccurrence of incidents with the same type of medical devices, at another place, at another time
- To encourage manufacturers to perform investigation and take corrective actions if necessary
- To enable the superior authority to monitor the investigation procedures and intervene when necessary

Although, the guidelines are voluntary and are not laws, they provide guidance for the application of the directives, and help to turn the directives into laws. Figure 125-2 is a flowchart that shows procedures and responsibilities of the competent authorities and manufacturers in the medical device vigilance system. Under the vigilance system guidelines, manufacturers should submit reports to the CA in the country where the incident occurred. Manufacturers must notify the CA within 10 working days when death has occurred, or within 30 days for all other incidents, by completing an initial report form. Each initial report is evaluated by the CA, who follows up with the manufacturer when necessary (ECRI, 1991; ECRI, 1993; ECRI, 1995).

Manufacturers are encouraged to perform investigations and take corrective actions. The CA should monitor a manufacturer’s investigation and intervene if necessary. At the end of the investigation, any information that is necessary for the prevention of further incidents (or the limitation of their consequences) should be shared in the form of a final report to all other CAs and the commission. Exchange of information between member states is essential, especially when measures must be taken as a consequence of an incident report (Pallikarakis et al., 1996). In cases of a recall, the responsible CA should ensure that information is given in a manner that avoids negative effects on those involved.

Confidentiality is important as well. The initial reports received by a CA are confidential, but the outcome of an investigation should be shared with other CAs in order to prevent similar incidents. On the other hand, dissemination of information that has not been verified can result in serious negative consequences for both manufacturers and patients. In order to meet these requirements, most member states have national medical device vigilance systems.

Although implanted devices receive regulatory approval before clinical use, many of them can create problems when applied to the patients, due to poor biocompatibility or inherent physiological human variability. Some devices have a finite performance time but, their use should be judged based on the benefits for the patient, as compared to the risks. It is often necessary to assess device performance after its application to the patient. Tracking systems for both patients and medical devices follow devices and assessing the clinical outcomes.

Tracking a device or implant means following the item from the manufacturer or importer to the user. Device traceability requires the gathering of data from manufacturers or importers, distributors, physicians, hospitals, and patients. Manufacturers and importers have a great responsibility, although they may have limited authority over the distribution network. The history of a device reflects product design, patient life expectancy, device cost, and other useful parameters. Maintaining a tracking system for implanted medical devices implies that it is possible to have information about the patient; i.e., to be able to have the patient under continuous observation, throughout the patient’s or device’s life, and to maintain the information in a confidential patient registry.

As previously mentioned, the approaches to medical device vigilance in the European Union countries prior to the implementation of the directives had no formal common communication structure between the involved authorities. The MDD has imposed requirements, and authorities recognize the need for a harmonized approach and cross-national exchange of information. In this era of rapid electronic communication, telematics will likely provide the appropriate means and tools for an effective, commonly accepted approach to information exchange. Such an approach has already been implemented in the field of pharmacovigilance, and a similar approach was explored with the European medical device information exchange system (EUROMEDIES) concerted action initiative (Pallikarakis et al., 1996). The information is available online at <http://www.ehto.org/aim/volume2/euromedis.html>. The project investigated requirements for a common telematics approach to information exchange in the field of medical device vigilance.

Conclusions

Although there is a strong global harmonization effort, the approaches followed in the field of medical device vigilance in different countries still vary, and no formal communication structure between authorities exists. The first step is the evaluation, acceptance, and use of a common medical device nomenclature system, which is a prerequisite for information exchange (Pallikarakis et al., 1996).

United States Food & Drug Administration

F. Blix Winston
Mount Airy, MD

The U.S. Food and Drug Administration (FDA) regulates medical devices primarily through the law known as the Federal Food, Drug, and Cosmetic Act, as Amended (“the FD&C Act,” or “the Act”). Regulations promulgated by FDA in Title 21 of the Code of Federal Regulations (CFR) spell out the broad provisions contained in the Act.

The FDA is made up of headquarters and field offices. The Offices of the Commissioner and functional centers, located in and around Washington D.C., include the centers for: Drug Evaluation & Research (CDER), Food Safety & Applied Nutrition (CFSAN), and Devices and Radiological Health (CDRH). FDA Regional and District Offices carry out the FDA’s field activities in the U.S., including manufacturing inspections and import examination. Foreign inspections are carried out from the headquarters office.

CDRH, currently located in Rockville, Maryland, is organized into functional offices. Device Evaluation (ODE) has primary responsibility for review of clinical and marketing applications; Compliance (OC) is responsible for inspections and enforcement; Science and Technology (OST) performs laboratory research and provides scientific support for Center activities; Surveillance and Biometrics (OSB) manages the problem-reporting programs and provides statistical support to CDRH. The Office of Health and Industry Programs (OHIP) is responsible for outreach, education, manufacturer, and consumer assistance, and the mam-mography quality standards program. These offices administer the programs and regulations that impact medical devices, and the companies that make them, throughout their life cycle: starting with the concept and design stages; during research, development and testing; during the application process; during manufacture; and through the device’s useful life.

Supplementing the regulations are hundreds of CDRH guidance documents, including manuals covering major processes like 510(k) and the Quality System requirements. All of the topics discussed in this chapter can be found on the CDRH web site (see References). Direct assistance is readily available through several mechanisms.

Laws and Regulations

Food, Drug and Cosmetic Act

The FDA’s legal authority, the 1938 FD&C Act, is a flexible law that has been modified several times. It defines broad concepts (e.g., adulteration and misbranding), sketches out procedures (e.g., Pre-market Notification), and directs the agency to develop implementing regulations. Section 201(h) of the Act defines the term “device” as “an instrument, apparatus, implement, machine, contrivance, implant, *in vitro* reagent, or other similar or related article including any component, part, or accessory, which is:

- Intended for use in the diagnosis of disease or other conditions, or in the cure, mitigation, treatment, or prevention of disease, in man or other animals; or
- Intended to affect the structure or any function of the body of man or other animals, and, which does not achieve any of its primary intended purposes through chemical action within or on the body of man or other animals, and which is not dependent upon being metabolized for the achievement of any of its primary intended purposes.”

The Act includes rules for classifying medical devices, provides for FDA review prior to marketing, governs device design and manufacturing, includes various rules for notifying FDA of certain actions, and contains provisions that apply both before and after marketing clearance is obtained. These requirements are enumerated and discussed throughout the chapter.

Major Amendments to the FD&C Act

1968 Radiation Control for Health and Safety Act

Before 1968, the FDA did not have the authority to regulate devices. Radiation-emitting consumer and medical devices, including X-ray machines, microwave products, lasers, cathode ray tubes, and sunlamps came became subject to FDA regulation with the 1968 RCHSA.

1976 Medical Device Amendments

The 1976 Medical Device Amendments gave FDA specific authority to regulate general medical devices. Along with other new provisions, Section 513 of the Act was changed to:

Describe a tiered classification scheme (class I, II and III), set forth requirements for each class of device “sufficient to provide reasonable assurance of the safety and effectiveness of the device,” and provide extensive detail about the way the device classification process works.

Safe Medical Devices Act of 1990

Major revision of the 1976 device provisions did not occur until 1990 with passage of the Safe Medical Devices Act (SMDA). SMDA included classification changes, changes to the 510(k) process, the authority to order recalls, adverse incident reporting by user facilities such as hospitals and outpatient treatment centers, post-market requirements such as device tracking, and reports of corrections and removals. The SMDA was followed in 1992 by the Medical Device Improvements Act, which largely only corrected conflicting provisions of SMDA.

1997 FDA Modernization Act

While SMDA focused only on medical device regulation, the 1997 FDA Modernization Act (FDAMA) affected all of FDA and had a strong impact on CDRH. Its effect can be seen in significant modifications to the PMA process and opportunities for meetings between the FDA and manufacturers before and during the review process. It clearly restricted the FDA’s role in regulating the “practice of medicine,” and required the agency to take a “least burdensome” approach when requesting data to support marketing applications.

Medical Device User Fee and Modernization Act of 2002—MDUFMA

MDUFMA authorized FDA to collect user fees to perform pre-market reviews and gave FDA authority over reuse of devices labeled “for single use only.”

Title 21, Code of Federal Regulations (CFR)

Regulations are “promulgated” by the FDA to flesh out the general provisions of the Act. The device volume, Parts 800–1299, contains nearly all of the regulations that affect medical devices. Other regulations that impact devices include Part 54 on Financial Disclosure Rules, Part 50 covering Patient Protection and Informed Consent, and Part 56 covering Institutional Review Boards.

Parts 862–892 in the device volume of the CFR cover the 16 classification panels that describe and classify about 1700 device types into class I, II, or III. Separate parts also cover Labeling (801), Medical Device Reporting (803), Establishment Registration, Medical Device Listing, Pre-market Notification (807), Pre-market Approval (814), Investigational Device Exemptions (812), and Quality Systems (820).

Medical Device Regulation

Device Classification

The Act devised a tiered approach to classification based on risk and the amount of regulatory control needed to provide “reasonable assurance of the safety and effectiveness of the device.” It places devices into one of three classes:

Class	Risk	Subject to	Approximate number in each class as of 1990*
I	Low	General controls	782
II	Medium	General controls and special controls	799
III	High	General controls, special controls, and pre-market approval	119
			1750

*These numbers are shifting as reclassification efforts proceed.

While most device types have already been classified, classification is a flexible mechanism that allows for reclassification when needed. Determining the classification for most devices can be done by using the Classification Database on the CDRH web site or searching through the classification panels in the CFR.

Each classification regulation in Parts 862–892 provides a brief description of the device and its intended use and gives its class and any particulars regarding marketing requirements. Proper classification is essential to understanding which regulatory requirements apply to a device. Center staff are always available to help determine classification.

General Controls

Class I devices, known as “General Controls,” are subject to the least regulatory control. They present minimal potential for harm to the user and are often simpler in design than Class II or Class III devices. Examples include manual surgical instruments and band-aids. Class I devices are subject to “General Controls,” as are Class II and Class III devices. General Controls include:

- Prohibition against adulteration (e.g., contamination) and misbranding (e.g., the wrong label on a device)
- Establishment registration, which tells the FDA where a firm is located
- Medical device listing, to notify the FDA that the device is being sold in the U.S.
- Manufacturing devices in accordance with the Quality Systems regulation, also known as the current “Good Manufacturing Practices” (GMP)
- Labeling
- Submission of a Pre-market Notification, or 510(k) application, before marketing a device

Over half of the 1700 classified device types, including most class I devices and a few class II devices, are exempt from 510(k). These exemptions can be found on the CDRH web site.

Special Controls

In 1976, amendments to Section 514 of the Act directed the FDA to develop mandatory performance standards for all Class II devices (radiological device performance standards are promulgated under the RCHSA). The Safe Medical Devices Act of 1990 changed the designation of Class II from “Performance Standards” to “Special Controls.” Special Controls apply to class II and III devices and may include one or more of the following: mandatory performance standards, guidelines, special labeling requirements, and post-market surveillance studies.

A Special Control becomes a requirement for a particular device, or a group of devices, when The FDA includes this designation in the CFR or requires a special control during the review process. Examples of current Special Controls include the classification for the Cranial Orthosis, 882.5970, and the performance standard for electrode lead wires and cables, 21 CFR Part 898.

Pre-Market Approval (PMA)

Class III devices are known as “PMA.” Compared to 510(k), PMA is a more rigorous, data-intensive approval process. Once the reclassification efforts are completed (by 2005), all devices remaining in class III will require a PMA (or a Product Development Protocol). In addition to devices classified as class III by statute, the 510(k) mechanism, which is itself a classification process, may result in a device being classified into class III and thus subject to PMA.

Standards

The FDA currently has promulgated one medical device mandatory-performance standard in Part 898 for electrode lead wires and cables. Performance standards also exist for radiation-emitting devices such as X-ray equipment. Recently, the FDA “recognized” hundreds of U.S. industry and international performance standards that can be used to establish safety and effectiveness in 510(k)s and PMAs. The standards page on the CDRH web site describes the use of voluntary standards, lists the ones recognized by FDA, and provides source information.

The Regulations Process, Advisory Panels, and the *Federal Register*

New regulations, or those being modified, are “promulgated” through a process that begins with a “notice of proposed rulemaking,” published in the *Federal Register* (FR). These FR notices usually ask for comments that are used by the FDA to modify proposed regulations. The modified regulation is usually published in the FR as a “final rule.” Note: Final rules contain “preambles,” which list the public comments received and the FDA’s response to them. They often contain valuable insights into the way the FDA develops its regulations. Advisory panels, whose names conform to the classification panels (e.g., the Cardiovascular panel), are composed of experts in their respective fields of specialization. Panels also include consumer representatives. They participate in the PMA review process and are called upon to advise the FDA when new device types are classified.

Pre-Marketing Requirements

Investigational Device Exemption

Clinical (human) trials of unapproved medical devices are subject to CFR Part 812, the Investigational Device Exemption (IDE) requirements. Investigational devices are exempted from most of the general controls, with the exception of adulteration. They

involve scrutiny by Institutional Review Boards (IRBs) and/or FDA, require signed informed consent from each subject who participates in the study, and are usually conducted to gather data on safety and effectiveness to support further development or marketing-clearance applications. Most PMAs involve clinical studies, whereas only about 15% of all 510(k) applications contain clinical data.

The two types of IDEs, significant risk (SR) and nonsignificant risk (NSR) studies, have slightly different approval routes. SR devices could be implants, could support or sustain life, or could present serious risks to health. SR devices require both IRB approval and an FDA-approved IDE application. Changes to an IDE application, made before the FDA has approved it, are referred to as “IDE amendments.” After the IDE is approved, related submissions are called “IDE supplements.” All types of IDE applications require a response.

NSR device studies are subject to the “abbreviated requirements.” The sponsor presents the study protocol to a local Institutional Review Board (IRB) and explains the reasons why the study is NSR. If the IRB concurs in the risk assessment and grants permission, the study may begin. Note: The FDA is not aware of NSR studies. While it is always advisable to schedule pre-IDE meetings with the FDA before submitting an IDE for a significant risk study, it may be advisable, as well, to request FDA review of the study design and protocol before beginning NSR studies. Both NSR and SR studies require informed consent of all patients in the study.

Premarket Notification—510(k)

Most devices are cleared through the Pre-market Notification or 510(k) process. FDA does not test devices as part of the review process; it assesses safety and effectiveness by reviewing information submitted in applications.

A 510(k) is not a form but a package of information, averaging about 100 pages. It includes: classifying and descriptive information about the device; certain information elements; technical information such as specifications, engineering drawings, and schematic diagrams; data from bench (and perhaps animal or clinical) testing; labeling and advertising (including instructions and operating manuals); and information comparing the device to one, or more, similar “predicate” devices that have been legally marketed in the U.S. 510(k) applications often contain information relating to performance standards, as well. The point of a 510(k) application is to establish “substantial equivalence (SE)” between the subject device and one or more “predicate” devices. A device is SE if it:

- Has the same intended use and the same technological characteristics as the predicate device, and information in the 510(k) does not raise any new issues of safety and effectiveness or
- Has different technological characteristics, and the information in the 510(k) demonstrates that the device is at least as safe and effective as the predicate.

Equivalence (and thereby safety and effectiveness), is demonstrated by comparing specifications and labeling, with performance data, or by showing conformance to FDA-recognized performance standards. For example, electromagnetic compatibility can be shown by conformance to IEC-60601-1-2.

When the 510(k) is submitted, an acknowledgment letter with a 510(k) number will be sent to the applicant. If the application is incomplete, the submitter will be asked to send the required information. A 510(k)s is placed on formal or informal “hold” if the reviewer needs more information.

A “substantial equivalence” determination by FDA serves to classify the new device into the same category as the predicate. A “not substantially equivalent” (NSE) determination results in automatic classification into class III. The review process, with flow diagrams, is discussed in the 510(k) Manual and is also described in Sec. 807.100.

The FDA Modernization Act introduced a new classification mechanism called “Reclassification of Automatic Class III Designation,” known informally as the *de novo* process. It allows low-risk devices the opportunity to receive marketing clearance following an NSE decision in lieu of going through the expensive and cumbersome PMA process.

FDA accepts three types of 510(k) applications: Traditional 510(k)s (as described above), Special 510(k)s, and Abbreviated 510(k)s. The traditional 510(k) is discussed in the guidance memorandum K86-3 and in the *Pre-market Notification, 510(k) – Regulatory Requirements Manual*.

An Abbreviated 510(k) includes a voluntary declaration of conformity with an FDA-recognized performance standard. Test data collected to demonstrate conformance do not have to be included in the 510(k), hence the content is somewhat abbreviated. A Special 510(k) can be submitted for modifications to existing devices that require a new 510(k). It includes a declaration that the applicant has followed design-control procedures and has completed necessary verification and validation activities in making the change. The FDA occasionally inspects records to verify that standards-related test data exist, or that design controls cited in a Special 510(k) were followed. The guidance document *Deciding When to Submit a New 510(k) for Change to an Existing Device* provides convenient flow diagrams that tell whether a new 510(k) should be submitted for the change. Special 510(k)s are reviewed within 30 days. Two guidance documents describe these alternative applications: *A New 510(k) Paradigm*, and *Questions and Answers Based on the New Paradigm*.

Although FDA maintains a 90-day “clock” on 510(k) review, 510(k)s are not subject to mandatory review times, as are IDEs and PMAs. Total review time averages approximately 110 days for all 510(k)s. The current median review time is 70–80 days. In the 2000, FDA received 4,202 510(k)s. Pre-inspection is not part of the usual 510(k) review process unless it is for a class III device. A 510(k) tutorial program, *Device Advice*, is available on the CDRH website. The Standard fee for 510(k) is \$3,490.00; the Small Business fee is \$2,784.00.

Pre-Market Approval

A Pre-market Approval application may be submitted as an original PMA or in modular format. It must provide data demonstrating that the device is safe and effective for its

intended use and that it will be manufactured in accordance with current GMP. By way of contrast, the FDA receives about 40 to 60 PMAs per year versus roughly 4,500 510(k)s. Rather than demonstrating safety and effectiveness (S&E) by establishing equivalence with another device, a PMA relies on performance data to demonstrate S&E. PMAs are larger and more complex than 510(k) applications. Six copies of the PMA must be submitted to the FDA. They are subject to a 180-day statutory review time. In addition to describing the PMA application process, FDA review, and post-approval requirements, Part 814 in the CFR also describes the “Humanitarian Use Device” process.

As part of the PMA review process, the FDA may seek an advisory review of portions of the PMA from an expert advisory panel. Following FDA approval, a “Summary of Safety and Effectiveness” will be published in the *Federal Register* and will appear in the PMA database online as well. Pre-PMA meetings are strongly encouraged. Numerous PMA-guidance documents exist, including the *PMA Manual*, device-specific guidance documents, and PMA administrative-review guidance. Average elapsed PMA review time, from log-in to final approval, averaged 364 days in FY-2002.

Changes affecting the safety or effectiveness of the device, such as design or labeling changes, require submission of a PMA supplement. Some PMA supplements can be as complex as the original application. Although the statutory FDA review is 180 days for PMAs and supplements, the FDA is committed to reviewing them in shorter timeframes, which it has reduced by accepting modular submissions and through the use of a real-time supplement process, 30-day notices, and expedited reviews. The Standard fee for PMA review is \$206,811.00; Small Business is \$78,508.00.

Product Development Protocol (PDP) and the Humanitarian Device Exemption (HDE)

Two alternatives to the PMA exist for class III devices: the “Product Development Protocol” (PDP) and the “Humanitarian Device Exemption” (HDE). The PDP process is based upon early consultation between the sponsor and the FDA, leading to a device development and testing plan that is acceptable to both parties. Once the PDP has been accepted, periodic reports are submitted to the FDA followed by a “Notice of Completion.” If the FDA finds that all requirements have been met, the PDP will be declared complete, and the device may go to market.

An HDE application for a Humanitarian Use Device is essentially the same as a PMA in both form and content but is exempt from the effectiveness requirement of a PMA. Though the HDE does not require scientifically valid data demonstrating effectiveness the application must contain sufficient information for the FDA to determine that the device does not pose an unreasonable or significant risk of illness or injury to patients. It must also demonstrate that the probable benefit to health outweighs the risk of injury or illness from its use.

Labeling

The CFR contains a number of labeling regulations, beginning with Part 801, which covers the general labeling requirements that apply to all medical devices. Section 801.1 requires that the name and place of business of the manufacturer appear conspicuously on the device’s label. Note: Section 801.4 defines “intended use” quite broadly, relating it to “...the objective intent of the persons legally responsible for the labeling...” and notes that labeling can include advertising, oral, and written statements made about the device. Usually, a device requires adequate directions for use by a layperson. “Restricted” devices that bear the prescription label (801.109), restricting their use to persons with professional training, are exempted from this requirement. The FDA does not have a list of restricted device types. In uncertain cases, CDRH reviewers will advise 510(k) or PMA applicants when the prescription label is required.

In addition to the general labeling requirements in Part 801, specific labeling requirements are found in the following CFR Parts: 812.5 for IDE devices, 809.10 for in vitro devices, 820.120 and 820.130 in the GMP regulation, and Parts 1010 through 1050 found in the performance standards for radiation-emitting products.

Registration and Listing

Initial Registration of Medical Device Establishment, form FDA-2891, which tells where a firm is located is required for U.S. and foreign manufacturers, specifications developers, contract manufacturers of finished devices, and importers (initial distributors). Registration is updated once a year on the FDA-2891a form, *Annual Registration of Device Establishment*, which the FDA mails out. Medical Device Listing on form FDA-2892, which tells FDA the firm has started selling the product, is required for any device marketed in the U.S., whether 510(k)-exempt or not. At the present time, original paper copies of the forms must be submitted to the FDA. Registration is not required prior to 510(k) submission; the forms must be submitted within 30 days of going to market.

Manufacturing Requirements

GMPs, Inspections, and Audits

The “Quality System” (QS) regulation in Part 820 (the current Good Manufacturing Practices (GMPs)) requires that most domestic or foreign manufacturers establish a system covering the design and manufacture of medical devices distributed in the United States. Some class I devices are exempt (by statute) from most of the Quality System requirement. GMPs address such topics as management organization and functions, design activities, control of materials and manufacturing processes, corrective and preventive actions, and label control. The Quality System regulation has been closely harmonized with European device requirements.

The CDRH web site contains extensive information on GMPs including the *Quality Systems Manual*, *Design Control Guidance for Device Manufacturers* and the

Quality System Inspection Technique (QSIT) Manual. The Design Control portions of the GMPs (820.30) come into play well before the stage is reached when a 510(k) or PMA is submitted to the FDA. Engineering, regulatory, and R&D staff should carefully study and implement these requirements at the R&D stage. They not only are required by FDA but when properly applied also greatly reduce the probability that design flaws will be missed and that expensive rework will be needed once the device goes to manufacturing. PMAs contain manufacturing information, and a current GMP inspection is required as part of the PMA approval process. While 510(k)s do not contain manufacturing information, they do contain information on the design, including schematics and drawings. A Special 510(k) includes a declaration that the applicant followed Design Control procedures when making significant changes to their product.

The FDA conducts inspections of domestic and foreign manufacturers of class II and III devices on a regular basis. Class I device manufacturers are inspected on an as-needed basis. The GMPs require that manufacturers conduct periodic audits of their quality systems by qualified personnel. Audits help companies to identify GMP deficiencies and make corrections to their quality systems. While audit results are designed to help management to do its job and are not accessible to the FDA, audit procedures are subject to FDA review. Materials such as the QSIT guide can help companies to prepare for FDA inspections. Note: Synergy between 510(k)/PMA data requirements and design control requirements can be exploited. Design documents, such as engineering drawings and data produced by design Verification and Validation steps are the same information submitted in 510(k) or PMA applications.

Post-Marketing Requirements

Reports of Corrections and Removals

Part 806 in the CFR applies to certain actions taken to correct or to remove products from the market. Many corrections or removals are done for economic reasons or to rotate stock. However, when they are done to reduce a risk to health posed by the device or to remedy a violation of the Act that could pose a risk to health (e.g., if the device is misbranded), a report must be sent to the local FDA office. Section 806.10 outlines the information that must be included in the report.

Records of all corrections or removals must be kept, even when they do not require a report to the FDA.

Recalls

Before the 1990 SMDA, the FDA did not have the authority to order companies to recall hazardous products. Following SMDA, Part 810 was added to the CFR. When the FDA finds that there is reasonable probability that a device will cause serious adverse health consequences or death, it may issue an order requiring the company to cease marketing the product and to submit certain information to the agency. It may also order the company to recall any violative product in the distribution chain. Part 810 goes into rather extensive administrative procedures that both parties follow, and notes specifically that the recall information may appear in the weekly FDA Enforcement Reports on the FDA web site. While recalls and corrections do occur, a well-managed Quality System will minimize their occurrence.

Post-Market Surveillance

The FDA may require manufacturers to conduct post-market surveillance studies to gather safety and efficacy data for certain high-risk Class II and Class III devices. 510(k) or PMA applicants are notified at the time of submission as to whether their device will be subject to post-market surveillance. This requirement comes into play primarily with Class III devices. Section 814.82 discusses post-approval requirements.

Tracking

Tracking is another regulation that was added following the 1990 SMDA. Part 821 describes the procedures that manufacturers of certain Class II or Class III devices (such as heart valves or infusion pumps) must set up so that they can track their medical devices down to the patient level. Like post-market surveillance, applicants will be notified during 510(k) or PMA submission as to whether their devices are subject to the tracking requirements. Cards or other feedback instruments are issued with a tracked device and are returned to the manufacturer by distributors and patients so that the manufacturer can provide a recipient list to the FDA upon request.

Medical Device Reporting (MDR)

The MDR regulation in Part 803 requires manufacturers and importers to report to the FDA within 30 days, whenever the firm becomes aware of information that reasonably suggests that one of its marketed devices:

1. Has, or may have, caused or contributed to a death or serious injury, or
2. Has malfunctioned, and that the device or a similar device marketed by the manufacturer or importer would be likely to cause or contribute to a death or serious injury if the malfunction were to recur

User facilities are required to submit reports of deaths to the FDA within 10 days, and to the manufacturer within 10 days for serious injuries.

MedWatch

Reports are submitted to the FDA on MedWatch (3500) forms. Manufacturers who receive a MedWatch report from a user facility or health care practitioner are required to submit a

3500A report to the FDA. There are two versions of the MedWatch form for individual reports of adverse events. Both are available on the CDRH web site. FDA form 3500A is the mandatory reporting form used by manufacturers and user facilities. FDA form 3500 is used by health professionals and consumers for voluntary reports. MedWatch forms allow trends to be identified and corrections to be made by manufacturers that otherwise might have been delayed. In addition to MedWatch forms, Part 803 requires manufacturers to submit baseline and five-day reports, if required. Information from MDR reports, Postmarket Surveillance reports, and other sources, such as the voluntary Product Reporting Program (PRP) and MeDSuN program, together with marketing-clearance data, contribute to the knowledge that the FDA analyzes in order to protect the health of the public.

International Harmonization, Service Providers and Reconditioners, and Enforcement Provisions

When the original GMP regulation was updated as the Quality System regulation, it was harmonized with the ISO 9001 series requirements. A new harmonization effort is the U.S./European Union Mutual Recognition Agreement, designed to allow the U.S. and participating countries to conduct quality-system inspections on behalf of each other. The FDA also has implemented the Third Party Review program, whereby 510(k)s for many devices may be reviewed by accredited bodies both in the U.S. and abroad. Information on both of these programs can be found under *A–Z Index* on the CDRH web site.

Service Providers and Reconditioners

In general, the FDA does not regulate service providers, such as firms that modify wheelchairs owned by patients. The FDA also does not actively regulate reconditioners and refurbishers who merely bring devices back to original specifications. One notable exception is entities reusing or reconditioning devices labeled “For Single Use Only.” Under MDUFMA FDA considers such entities, including hospitals and “Third Party Reprocessors,” as manufacturers in some cases. All regulatory requirements, including 510(k) and PMA apply to these new manufacturing entities.

Enforcement Provisions

The FDA can apply a variety of enforcement actions to U.S. and foreign manufacturers and the devices that they distribute within the U.S. when devices or manufacturing processes are discovered to be in violation of the Act.

When significant deviations from GMP requirements are found during an inspection, the FDA may issue a warning letter which lists the deviations and notifies the firm that

further action may be taken if the deviations are not corrected. Further action could include citations, seizure of goods, prosecution of the firm, or the imposition of civil penalties (fines). The FDA also may utilize these enforcement provisions when it learns of imminent hazards through adverse incident reporting. Imported goods can be detained for testing or refused entry when found violatory by the FDA.

Guidance

The *Good Guidance Practices* (GGP) database can be used to find most guidance documents. Alternatively, *Topic Index* can be searched by keyword. Numerous “pages” have been added to the web site, such as the GMP or MDR pages, which provide a central location for guidance.

IDE and PMA premeetings can be scheduled with the appropriate review divisions in the Office of Device Evaluation (ODE). The Division of Small Manufacturers, International, and Consumer Assistance (DSMICA) also offers direct assistance via telephone (800) 638–2041 or (301) 443–6597, via e-mail (dsmica@cdrh.fda.gov), or via fax to: (301) 443–8818.

Further Information

All existing CDRH guidance and references can be ordered in hard copy from DSMICA via fax: (301) 443–8818, Attn: Publications.

Tort Liability for Clinical Engineers and Device Manufacturers

Edward P. Richards, III

Director, Program in Law, Science, and Public Health
Paul M. Hebert Law Center, Louisiana State University
Baton Rouge, LA

Charles Walter

College of Engineering, University of Houston
Houston, TX

This chapter discusses the legal liability of clinical engineers (CEs) whose negligence causes persons to be injured by the medical devices for which the engineer is responsible, and the liability of the manufacturers of medical devices that injure people. These injuries are usually to patients but they also can be to the medical care providers who use the devices, and even to bystanders. The magnitude of injuries can range from minor skin irritation due to an improper electrode jelly on an EKG electrode, to catastrophic injuries and property damage from the explosion of an operating suite from the untimely combination of an ignition source and explosive anesthesia agents. The chapter is divided into two sections, reflecting the different legal rules for the personal liability of individual engineers (malpractice) and the corporate liability (products liability) of medical device manufacturers. While the legal risks to manufacturers are much higher, both in terms of the number of claims filed and the dollars at issue in those claims, the personal impact of a claim against an individual engineer can be devastating. Understanding the legal basis for liability is a necessary part of effective clinical engineering risk management.

Personal Liability for Malpractice

There are relatively few malpractice claims against CEs for injuries caused by their actions, although there is reason to expect that such claims will increase. Traditionally, most CEs worked for corporate entities, usually hospitals and supply companies, who were the target defendants when a medical device related injury claim was filed. With changes in the industry, an increasing number of CEs work for contract service agencies and as independent contractors. This will encourage plaintiffs to sue the engineer personally because there is no longer a “deep-pocketed” corporate employer to pay the claims. Even if the plaintiff does not expect to collect damages from the engineer, the pressure of a lawsuit and personal liability can encourage the engineer to help the plaintiff’s claim against the hospital or supply company as a condition of being allowed out of the lawsuit.

As indicated above, most personal claims against CEs will be for professional malpractice, which is based on negligence law. To establish negligence, a plaintiff must prove four things:

1. A duty
2. Breach of a standard of care
3. Causation
4. Damages

“Duty” is the legal relationship between the injured person and the CE. The hospital or other health care provider who supplies the device has a duty to the patient to ensure that the device is properly maintained and working correctly. This duty is shared by the CEs, who actually work on the device. CE supervisors have a duty to carry out their responsibilities correctly, which includes ensuring that those under their supervision carry out their work properly. For example, assume that a patient is injured by a negligently maintained medical device in the CCU at St. Elsewhere Hospital. The patient sues both the hospital and Jane, the CE who works for the hospital. If there had been negligence, the hospital would be liable regardless of which CE was responsible. Jane’s liability depends on whether she worked on the device personally or was responsible for maintaining that device directly or through supervising other CEs. If Jane works in the outpatient department, did not work on the device, and has no responsibility for CCU devices, then she does not have a legal duty to the injured patient. If, however, she is the supervisor of the

clinical engineering department, then she would have a legal duty to the patient to ensure that her employees properly maintained the device.

Duty can be more complicated for third-party service groups. CEs who perform third-party service always have a duty to others for the work that they do and for their supervision of others. Unlike hospital-based CEs, service contracts may limit the CE’s access to the devices and the work that they are allowed to do. Thus, while the head of the hospital CE department might have an ongoing duty to monitor all of the hospital’s devices, a contractor CE will only be responsible for the devices specified in the contract, unless it includes all of the hospital. Contractor CEs must ensure that the hospital gives them adequate access to the devices that they contract to maintain. Otherwise, they could be legally liable for devices to which they do not have physical access. It is likely that the courts will find that while hospitals may contract for outside service for devices, the hospital retains liability if that service is not rendered correctly. This is because maintaining safety devices is usually a “nondelegable duty,” which means that the party that is originally charged with ensuring safety might not escape that obligation.

“Standard of care” refers to what a reasonable, competent CE would have done under the same circumstances. There are three ways for the plaintiff to establish the standard of care. The most common is to call another CE to testify as an expert witness as to what he or she believes the CE should have done. Standard of care also can be established through published standards, such as those promulgated by governmental agencies or organizations such as the Association for the Advancement of Medical Instrumentation (AAMI), or through manufacturers’ maintenance manuals. CEs also must abide by any internally promulgated standards, such as hospital maintenance schedules or specific contracts for service. For example, if hospital guidelines are stricter than industry standards, courts have found that the internal guidelines are binding. The CE can present evidence that refutes the plaintiff’s proffered standard, and the jury will decide which to apply.

Once the plaintiff has established the alleged standard of care, he or she must show that the defendant did not adhere to the standard of care. The defendant might argue that he or she did follow the standard of care, or that he or she had a valid reason for not following the standard of care in the particular situation. Such defenses are stronger if the valid reasons for deviating from the standard of care were documented at the time the work was done.

“Causation” is the evidence that links the defendant’s actions to the plaintiff’s injuries. For example, the defendant might have negligently maintained a ventilator, though the patient died of a pulmonary embolus that was unrelated to any potential problems with the ventilator. Causation is especially controversial when there is an alleged intermittent device failure that cannot be detected after the accident, and where the patient’s injury was likely due to the underlying disease.

“Damages” are measured by the costs of compensating the plaintiff and the plaintiff’s family for the injuries caused by the defendant’s negligence. They can be very high when an otherwise healthy person is killed or permanently incapacitated by an injury and can include lost wages, past and future medical care, and other expenses related to the consequences of the injury. Conversely, if the patient is severely ill, with no chance of recovery, or elderly, the courts will award relatively little compensation because the patient’s financial and physical condition is not worsened as much, even by death.

To avoid liability, CEs must ensure that their responsibilities are well defined and manageable. They must see that their work is properly documented and that those whom they supervise are competent and that their work is performed with the appropriate standard of care. CEs must avoid situations where they are not given adequate resources or control to ensure that the equipment for which they are responsible is properly maintained. For example, accepting a job that takes 12 hours but that must be done in 8 is likely to lead to injury and liability for CE malpractice.

Products Liability

Historically, liability for injuries caused by defectively designed or constructed products, or products for which there were inadequate warnings of dangers, was determined by the same negligence principles as CE malpractice discussed above. An injured person had to prove that the manufacturer did not follow the appropriate standard of care in designing or building the product and that the injury was caused by this failure to follow the appropriate standard of care. More difficult, the plaintiff would have to show that he was in “privity” with the manufacturer, which usually meant that he had purchased the product from the manufacturer. These rules dated from before the industrial revolution and anticipated that individuals would purchase products directly from the artisans who build them.

In an industrial society where products flow through many layers of distribution, the requirement of privity made it impossible to sue the manufacturer for most product-related injuries. Driven by the then-new phenomenon of automobile accidents due to poorly manufactured cars, courts abolished the privity rule in the early 20th century so that injured persons could sue the car manufacturer as well as the dealer where they purchased the car. Courts then extended the right to sue to nonpurchasers who were injured by defective products, such as passengers in cars, or cars driven by persons other than the purchaser.

Abolishing privity helped persons who had been injured by products such as cars that pass through the distribution chain with little change or risk of hidden damage by others before sale. Cheaper, more easily damaged consumer products still left the plaintiff with the problem of proving that the defect causing the injury was caused by the manufacturer and not by subsequent mishandling. The classic example is injuries caused by exploding Coke bottles. Old-style Coke bottles were made of heavy glass so that they could be recycled and refilled. (Older readers might remember checking bottles for place of origin and being amazed at how far bottles traveled in their lifetime; some might even recall finding roach carcasses lodged in the bottom of the recycled bottles.) While this practice was environmentally friendly, it increased the risk of an undetected defect in the glass, and the thickness of the glass made it particularly dangerous when it exploded under the pressure of the carbonated liquid. This combination led to many serious hand and eye injuries.

Plaintiffs then would sue the local Coca-Cola bottler and distributor, arguing that bottles broke in normal use because of either a defect in the glass or over-carbonation, another common problem. The manufacturer would deny responsibility, arguing that the defect was caused by mishandling by the delivery truck, the grocery stockers, the bar owners, or others who served as an intermediary between the customer and the manufacturer, or by the plaintiff himself. Because the manufacturer’s duty was to produce a bottle that met the industry’s standard of care, which it did, the plaintiff could not argue that bottles should be designed so that they were safe to use, even if mishandled.

The courts first attacked this problem with an old doctrine called *res ipsa loquitur*. Roughly translated, this means “the thing speaks for itself.” It originated in a case where a barrel of flour rolled out of a second-floor warehouse loading door and fell on a bystander. The warehouse owner argued that the victim had to show why the barrel had rolled out of the window, to prove that the owner was negligent. The court ruled that plaintiff did not have to prove a specific negligent action if plaintiff could show that the thing causing the injury was in the defendants’ exclusive control and that such accidents generally did not occur in the absence of negligence. Thus if the jury believed that the defendants must have been negligent if a barrel had rolled out of the warehouse, then the burden would shift to the defendants to provide an explanation for the accident, wherein they were not negligent.

As applied to the Coke bottle cases, the plaintiff did not have to prove a specific defect in the exploding bottle. Unfortunately, subsequent mishandling still was a defense, and the plaintiff would have to show that the defect had occurred while the bottle was under the control of the defendant. The more intermediaries between the injured customer and the bottle, the more difficult it was to rule out subsequent mishandling. This fact made these cases very difficult to prove and left the manufacturer free to keep using a dangerous design as long as it met the standards of the industry. Economists and legal scholars argued that this was inefficient in that it did not provide an appropriate incentive to reduce injuries by building safer products. This led courts and legislatures to turn to another old doctrine—strict liability.

Strict Liability

Historically, strict liability was applied to persons engaged in extremely hazardous activities such as keeping wild animals and constructing blasting. If these activities caused injuries to others through no fault of the injured person (e.g., that the plaintiff had entered the tiger’s cage without permission would be a defense), there would be liability without any need to show negligence. More importantly, the defendant could not argue that it had complied with the standard of care and thus should not be liable. For strict liability to be found, the only question is whether the defendant’s actions injured the plaintiff though no fault of the plaintiff’s. The rationale underlying the adoption of strict liability is that there are some commercial activities with significant benefits that cannot be made safe. Rather than ban them, it makes better economic sense to allow them, but to require those who engage in them to pay for injuries that they cause, without regard to fault. This thinking influenced the California Supreme Court when it decided the case of *Greenman v. Yuba Power Products Inc.*, 377 P.2d 897 (Cal. 1963), which is seen as the first modern products liability case.

Greenman was a do-it-yourselfer who owned a multipurpose machine called a Shopsmith. The Shopsmith could be a saw, drill press, lathe, or other power tool, depending on how the user set it up. When Greenman was using it as a wood lathe, the chuck that held the wood came off the machine, and the turning piece struck him in the head, causing severe injuries. Investigation showed that the part had failed because it was attached with inadequately sized bolts. Greenman filed a lawsuit several months later, claiming that the machine was defective and violated the commercial warranty implied by the California Commercial Code. The manufacturer objected, pointing out that Greenman had not filed his claim in time to meet the statutory requirements. The court agreed that Greenman could not bring the warranty claim because the filing deadline had passed, but allowed Greenman to sue on the theory that the product was not fit for the intended use, irrespective of whether it met the standard of care or violated the statutory warranty. Thus the court launched the

modern products liability claim that allows a jury to find a manufacturer liable if the product is defective and dangerous, even if it meets the standard of care. Applied to the Coke bottle cases, the standard of care would require the manufacturer to design bottles that could withstand mishandling, even though other manufacturers did not do so.

Shortly after *Greenman*, the American Law Institute, a private body that promulgates suggested legal standards, incorporated the rationale for *Greenman* into an influential document called the *Restatement of Torts*, 2nd edition, (1965).

402A. SPECIAL LIABILITY OF SELLER OF PRODUCT FOR PHYSICAL HARM TO USER OR CONSUMER

- One who sells any product in a defective condition unreasonably dangerous to the user or consumer or to his property is subject to liability for physical harm thereby caused to the ultimate user or consumer, or to his property, if
 - the seller is engaged in the business of selling such a product, and
 - it is expected to and does reach the user or consumer without substantial change in the condition in which it is sold.
- The rule stated in Subsection (1) applies although
 - the seller has exercised all possible care in the preparation and sale of his product, and
 - the user or consumer has not bought the product from or entered into any contractual relation with the seller.

Nearly all states have adopted some form of strict liability as defined in Section 402A. The policy behind Section 402A and the various modifications adopted by the states is to encourage manufacturers to engineer products so that they do not fail, or if they do fail, they fail in a way that does endanger users or others. The key provision is (2)(a)—strict liability applies even if the manufacturer “exercised all possible care in the preparation and sale of his product.” It is no defense for a manufacturer to claim that it built the device to industry standards, or even that the product was built better than any other device on the market. Thus, if an EKG machine shocks a patient because the isolation transformer is defective, it will not be a defense for the manufacturer to claim that it bought the best transformers on the market.

Product Liability Defenses

Strict liability is not absolute liability. There are several defenses for products in general, and additional defenses for medical devices. The most fundamental is that the defective product did not cause the injury at all. This defense arises frequently in clinical engineering because the most critically ill patients tend to be the most instrumented. If a pacemaker fails and the patient dies of an arrhythmia that the pacemaker was implanted to control, then it is highly likely that the defective device caused the injury. The hospital itself also could be liable if the nursing staff failed to notice the arrhythmia because they were not monitoring the patient properly. If an electronic thermometer fails, masking a patient’s fever, it is unlikely that it is what caused the patient’s death from pulmonary embolism a few minutes later.

Misuse

Another common defense in clinical engineering is misuse. Thus, if a physician incorrectly sets up an anesthesia machine and injures a patient, the device manufacturer might not be liable. Misuse is a complicated defense because the courts have created the doctrine of foreseeable misuse; i.e., manufacturers have a duty to design products to prevent foreseeable misuse. Foreseeable misuse includes known common practices, such as turning off alarms, and practices that come to the attention of the manufacturer through incident reports or investigations. For example, when it became known that some physicians improperly assembled anesthesia machines and thus endangered patients, the manufacturer was found to have a duty to redesign the machine so that it could not be assembled improperly.

Learned Intermediary

Another facet of misuse is the expected expertise of the user. Historically, pharmaceutical manufacturers were allowed to assume that their drugs would be prescribed by physicians who were trained in pharmacology. This allowed the drug manufacturers to assume that warnings and other information would be read by an expert who could understand medical terminology and who would independently determine the suitability of the drug for the individual patient. This is called the “learned intermediary doctrine,” and it insulates drug manufacturers from liability for physicians who incorrectly prescribe drugs, as long as the physician was provided the necessary information to prescribe the drug properly. In contrast, when drugs are sold over the counter (i.e., without a prescription), they must be labeled so that any consumer can use them safely. As drug manufacturers increase their direct marketing of prescription drugs to consumers, the courts are limiting their ability to claim the learned-intermediary defense. In a recent case, a state court found that the manufacturer of Norplant, a subcutaneous, long-term contraceptive, would be limited in the way it used the learned-intermediary defense because it advertised the product directly to consumers. The court allowed the patients to argue that the manufacturer should have provided safety information directly to the patients, rather than only to the physicians prescribing Norplant.

The courts have never clearly adopted the learned intermediary defense for medical devices. This is partially because, unlike pharmacology, physicians do not receive any training in clinical engineering. It also is due to the broader user base for medical devices. Unlike prescription drugs, which until recently were only prescribed by physicians, medical devices were frequently used by nurses and technicians who came from various backgrounds. Without a learned intermediary defense, medical device manufacturers must design and label devices so that they can be safely used by nonphysicians. This has become a particular problem as medical devices are routinely used in home health care, often without a medically trained user. Such uses demand well-designed training

materials, device manuals, and labels on the device for safe use. The courts consider these explanatory materials as part of the device itself. If they are inadequate or do not provide appropriate information for the actual users of the device, they will be considered defective. Many medical device claims are based on defective labeling, rather than defects in the physical device itself.

Federal Preemption

In 1976, the FDA was given the authority to regulate medical devices through the Medical Device Amendments (MDA). Devices that were on the market at that time were "grandfathered" and could continue to be sold, pending future review by the FDA. New devices had to be submitted to the FDA before sale. If the manufacturer can show that the new device is substantially equivalent to a device that has been on the market since before 1976, and that the device is manufactured to the FDA's standards, then the FDA must permit the device to enter the stream of commerce with only a cursory review to determine whether it is the same as a pre-1976 device and passes basic safety standards (e.g., it will not shock anyone or come apart inside the patient. It is called 510(k) clearance, for the statutory section that establishes the procedure. Devices that are not equivalent to pre-1976 devices are subjected to an intensive new device approval process that is similar to the new drug approval process. This process can require extensive clinical trials and many redesigns of the device and its labels and manuals. While this intensive review of new medical device technologies is costly and time-consuming, it has an important legal advantage to the manufacturer: Design elements and labels specifically considered and approved by the FDA receive some protection from state product liability claims. For example, if a pacemaker lead fails, killing a patient, the plaintiff must show that the lead was defective, if he is to recover. If the lead's insulation failed because it became damaged during manufacture, then the plaintiff has a case. In many situations, however, the product was properly manufactured. Because pacemaker leads are delicate and can fail without being defective, the plaintiff will claim that the design is defective, perhaps because the manufacturer did not use a sufficiently strong alloy for the wire. If the FDA reviewed and approved the wire used as part of its review of the device, the courts have ruled that the plaintiff cannot second-guess the FDA by claiming that the wire should have been designed differently. If the FDA approved the label for the device, then the plaintiff cannot claim that the label was defective because it did not provide adequate instructions or warnings.

Section XII

Professionalism and Ethics

Gerald Goodman

Assistant Professor, Health Care Administration
Texas Women's University
Houston, TX

The principal professional challenge in clinical engineering is in managing the risks inherent in technology. However, that role must be viewed more globally than it has been in the past. Previously, we have discussed the clinical engineer's role from an organizational context: the clinical engineer as an engineering employee of a health care organization or service provider. However, professional roles are not bound by organizational structure and professionals have a global responsibility. It is the difference between engineers practicing as individuals, and engineers practicing as a profession.

Engineers traditionally have practiced in an organizational setting. Today, an increasing percentage of traditionally independent professional practitioners, including physicians and attorneys, now work in complex organizations. Complex organizations develop their own control over professionals. Bosses, not colleagues, rule. The salaried professional often has neither exclusive nor final responsibility for his or her work.

The image of rational, technical work routines aimed solely at client welfare is difficult to sustain in many service establishments, whatever the occupation. For example, in hospitals, patients might come to feel that much of what goes on is dictated by non-medical considerations, and that many rules for patient management are designed for the convenience and comfort of the staff (Wilensky 1964).

The Service Ideal of the Professional

The service ideal of the professional is the devotion to the client's interests, more than to the personal or commercial profit (Wilensky, 1964). The service ideal should guide decisions when the two are in conflict. Expression of the service ideal is embedded in the professional role orientation and practice autonomy that professionals traditionally have held. The success of a claim to professional status is measured not only by the success of a claim to exclusive technical competence, but also by the degree to which the practitioners adhere to the service ideal and its supporting moral norms (Wilensky 1964).

One large component of the work of engineering professionals involves the impact of technology on public health. These effects are seen in increased cases of cancer due to environmental pollution or occupational exposure to hazardous chemicals, disabilities stemming from transportation-related accidents, and deaths and injuries resulting from industrial accidents. Interwoven into this matrix of technologies and risks are the yet-to-be-revealed risks from evolving technologies such as gene manipulation.

As modern technology becomes more complex, so does the assessment of environmental and safety risks, including an array of moral issues and dilemmas. Herkert identifies five such issues, including the overlapping of political or normative judgments with scientific judgments, the potential for manipulation of risk assessments to legitimize deployment of risky technology, the determination of the value of life used in risk assessment, the imposition of risk on those less empowered, and the distribution of risks and consequences across geopolitical or cultural boundaries (Herkert, 1994).

Sol Linowitz, in his 1994 book *The Betrayed Profession*, attributes the law's faltering ethics to the transformation of the profession from a noble calling to a legal-services industry. An alternative view of the legal profession attributes the problem of faltering legal ethics as the "profession mirroring society" meaning that Americans get the law and the lawyers they deserve.

Is it fair to expect more ethical conduct from a lawyer than from a businessman? What about the ethical behavior of a professional engineer? Who will represent the public's interests with regard to ethical concerns over the impact of technology on society? The answer lies in the basic definition and attributes of profession itself, which is discussed in this section.

Actualizing the Service Ideal

The engineering profession is considering how engineering as a profession should address what engineers see as an ethical responsibility to inform the public of the risks of new technologies. Attitudes to overcome include the engineer's preoccupation with the technology itself, the attitude that the public can not make an informed decision because they lack a technical background, and an overwhelming bias of engineers toward quantification in the evaluation of risk (if the numbers look good, then it must be good). As has been noted of other professions, experts make value choices at the expense of the people affected by the technology.

Solutions proposed by the engineering profession are twofold: Change the basic engineering curriculum to include required courses in the role of engineering and society, and provide protection for engineers who apply ethical principals in the exercise of their professional judgment. The similarity in solutions between engineers and physicians appears in mandatory medical ethics courses for medical students.

Is the educational system the right venue in which to instill a sense of ethics into aspiring professionals? According to Friedson, the educational system is the single most significant factor in determining the performance of the practicing professional (Friedson, 1971). For example, the medical student is socialized to become a physician through the medical education system.

If an occupational group wants to use the privileges society affords a profession, its leadership must insist on ethical behavior in relation to those privileges. As for medicine, engineering, and the application of technology in health care, public trust has been substantially diminished in the recent past due to seemingly uncontrolled technologies used with, at a minimum, the passive approval of medical and engineering professionals.

Educational programs aimed at aspiring professionals may help improve professional ethics. For engineering, a vehicle for actualizing that ethical concern is equally important.

This section begins with a chapter on professionalism by this author, followed by a chapter on advocacy and ethics in the clinical engineering profession. The next three chapters describe professional organizations at the international, national, regional, and local levels all of which represent ways by which professionalism is nurtured. The first chapter describes the American College of Clinical Engineering (ACCE), the first international professional organization dedicated to the advancement of health care by clinical engineers. Efforts of the ACCE to enhance the profession of clinical engineering through such means as Advanced Clinical Engineering Workshops, a code of ethics, and advocacy are detailed. The next chapter describes the New England Society of Clinical Engineering, an example of a vibrant regional organization, along with its programs aimed at enhancing the professional stature of its members and of the profession at large. The next chapter describes the New York City Metropolitan Area Clinical Engineering Directors Group, one of the most active local organizations for clinical engineering. The section ends with two chapters on certification. The first presents the history and current status of clinical engineering certification at the international level, and the second describes clinical engineering certification in Germany on the national level.

Gerald Goodman

Assistant Professor, Health Care Administration
Texas Women's University
Houston, TX

The word "profession" is defined in any standard dictionary as a calling requiring specialized knowledge, and often long and intensive academic preparation—a principle calling, vocation, or employment. "Professional" and "professionalism" are, likewise, defined by referring to some aspect of the root word, "profession." The dictionary definitions of "profession," "professional," and "professionalism" are not of real consequence in that most people, when defining these words, refer to a perception of what these words connote, to a mental picture or image of what a profession is, or how a professional looks (for example, abstract thinking, as opposed to manual labor; a suit and tie, as opposed to a uniform; a learned person such as a physician or a lawyer). This perception of a professional is cultural, having been nurtured carefully by those who most directly benefit from the mystique of the professions.

The background study of professions that is relevant to an analysis of the clinical engineering profession has four parts. The first part develops a baseline definition of profession. The second part traces the historical development of profession, looking for a developmental history of professions. The third part looks at the relationship of a professional to an employer. The fourth part looks at legal restraints such as licensure. This chapter concludes with a discussion of the role of professional societies in the professionalization process.

Definition of Profession

There is a dominant, contemporary mode of thinking about professionalism termed the "attribute approach" (Dingwall, 1976). The attribute approach begins from the basic assumption that it is possible to list fixed criteria for recognizing a profession on which there will be a general consensus. These criteria can be used to distinguish between professions and other occupations in a relatively clear and unproblematic fashion. Parsons (1954), Freidson (1971), and Illich (1973) have followed the attribute approach heavily. The following paragraphs discuss these three writers' definition of "profession."

Sociological Definition

"Profession" can be defined in sociological terminology as a cluster of occupational roles, or roles in which the incumbents perform certain functions valued in the society in general (Parsons, 1954). The profession is distinguished by the largely independent trusteeship exercised by the incumbents. Its roles are one important part of the major cultural tradition of the society. The profession's typical member is trained in that tradition, usually by a formally organized educational process, so that only those with the proper training are considered qualified to practice the profession. Furthermore, only the members of the profession are treated as qualified to interpret the tradition authoritatively and, if it admits of this, to develop and improve it. Finally, although there usually is considerable division of labor within such a group, a substantial portion of the members of the profession will be concerned largely with the "practical application" of the tradition to a variety of situations. Here, it can be more useful to others than to the members of the profession itself. The professional person is thus a "technical expert" of some order by virtue of his mastery of the tradition and the skills of its use.

The profession may be regarded sociologically as a mechanism of social control. The teaching profession helps to socialize the young, to bring them into accord with the expectations of full membership in the society, or to bring the young back into accord when they have deviated. The legal profession can be presumed to do this and two other things. First, the legal profession can forestall deviance by advising the client in the ways that will keep the client better in line and cool him off in many cases. Second, if it comes to a serious case, the lawyer can implement the procedure by which a socially sanctioned decision about the status of the client is arrived at. In the dramatic cases of criminal law, the determination is whether the client is innocent or guilty of a crime.

Another attribute of a profession is that of integrity (Parsons, 1954). The lawyer tends to be both permissive and supportive in her relationships with her client. However, there is more to the picture. As a member of this great profession, she accepts

responsibility for its integrity, and her whole position in society focuses that responsibility upon her.

Classical Definition

Freidson (1971) notes that the discussions have been so fixed on a definition of "profession" that not much analysis has been made of the significance and consequences of some of the elements common to most definitions. The most critical elements are organizational in character and are related to the organization of practice and the division of labor. These elements are critical because they concern the facets of a professional occupation that are independent of individual motivation or intention. This may minimize the importance to behavior of the personal qualities of intelligence, ethicality, and trained skill that are imputed to professionals by most definitions.

The key institutional element is autonomy, which is the quality or state of being independent, free, and self-directing. For the professional, control over the content and the terms of work are self-directing his work. Self-direction is seen to be the key institutional element included in most definitions of "professional." The more self-directing an occupational group has become, the more likely a legal or political position of privilege has been obtained to protect it from encroachment by other occupations. This is stated to be the primary function of licensure.

A second institutional element related to self-direction is control of production and application of skill and knowledge. Control and knowledge is through the extended period of education controlled by the profession in an exclusively segregated professional school, rather than in a liberal arts school, and through curriculum that includes some special knowledge and skill necessary for the occupation. The professional school and its curriculum also constitute convenient institutional criteria for licensure, registration, or other exclusionary legal devices.

A third institutional element is the adoption of a code of ethics, which is a method of persuading society to grant the special status of autonomy. Thus, most of the commonly cited attributes that are used to define professions could be seen either as consequences of their autonomy or as conditions that are useful for persuading the public to grant such autonomy. The attributes that are used to define a profession contribute markedly to the mystique of that profession. It becomes difficult to say which came first—a definition or a mystique. In actuality, they have developed together (Freidson, 1971).

Political Definition

Profession is a concept that is used solely to achieve the successful mystification of a class interest (Dingwall, 1976). Illich (1973) defines the professional as someone who tells another what they need, and claims the power to prescribe. Professionals not only recommend what is good, but also actually ordain what is right. Neither income, nor long training, nor delicate tasks, nor social standing are the marks of the professional. Rather, it is his authority to define a person as a client, to determine that person's need, and to hand the person a prescription. This professional authority comprises three roles: The salient authority to advise, instruct and direct; the ethical authority that makes its acceptance not just useful but obligatory; and charismatic authority that allows the professional to appeal to some supreme interest of his client that outranks conscience. "By not taking the craftsman's counsel, a person is a fool. For not taking liberal counsel, someone is a masochist. Now the heavy arm of the law may reach out when they escape from the care that their surgeon or 'shrink' have decided upon for them" (Illich, 1973).

A Limitation of the Attribute Approach

Dingwall (1976) finds a central problem with the attribute approach to defining profession in that such attempts assume that the concept has a fixed meaning. Words do not have fixed and unequivocal uses according to some calculus of rules. Their sense is found by a process of filling in until someone can say that they understand. No one can define what profession is. All that anyone can do is elaborate what it appears to mean, to use the terms, and to list the occasions on which various elaborations are used.

Historical Development of Professions

The development of occupational groupings into professions can be traced from two aspects. The first traces the elements of the professionalization process. The second traces a natural developmental history of the professionalization process. Timperley and Osbaldeston (1975) and Wilensky (1964) wrote on the developmental and historical background of professions. A review of some of their work follows.

Elements of the Professionalization Process

Timperley and Osbaldeston (1975) identify five key elements in the process of professionalization. They are the level of activities to be performed, the achievement of status and prestige, the existence of a territory (and, hence, a boundary), the performance of service, and the prerequisite of prescribed educational training.

The educational background of members of an occupational association with professional aspirations is an important determinant of that association's status. Proper educational background is usually a prerequisite for entry (and, increasingly, for practice) in a profession. However, in the period of growth of an occupation in terms of numbers working within it and the range of functions performed, entry into that occupation will be loosely controlled, particularly given the need to build up the occupation and the range of tasks and functions.

The educational background of members of any formal occupational association is, to a large extent, governed by such factors as the speed of growth and development of an occupation in demand terms and the link with labor supply, the perception by people entering the occupational areas of the need for a formal identity, and particularly the amalgam of motives for setting up and perpetuating an occupational association.

Such motives might include the need for identity or status, the need for protection, and the need for improving standards in the area. All of these factors would create demands for controls once an occupational group has reached a point where it became necessary for competence to be defined and for functions to be ordered. In fact, it is important to distinguish between the control aspects of forming an occupational organization, which implies the mechanisms to be used to reach an end, and the achievement of a formal professional status.

Although the formal aims of professional associations might not emphasize collective bargaining as an activity, the individual member can, and does, use membership in, and qualifications from, a professional body as a bargaining instrument in his relationship with his employer or potential employer. The development of a strong identity enables professional associations to obtain considerable influence over the personnel activities of employers (Timperley and Osbaldeston, 1975).

A Natural Developmental History of Professions

Wilensky (1964) sought a natural development history of professionalization through the analysis of the developmental histories of 18 occupations. He hoped to document an invariant progression of events, a path along which the occupations had all traveled to professional recognition. Did the less established and marginal professions display a different pattern?

The progression of the occupation toward professionalization can be determined by noting first the present professional status of the occupation, and then the sequence in which six crucial factors occurred in the progression of the occupation toward professionalization. The six factors are the appearance of (1) the first training school; (2) the first university school; (3) the first local professional association; (4) the first national professional association; (5) the first state licensure law; and (6) the first formal code of ethics.

Schools and Associations

Before any of these six factors came into play, a job needed to be performed. The sick needed nursing, and hospitals needed managing. The original practitioners, by necessity, came from other occupations. The question of training soon arose. In four of the six established professions (in the study), university training schools appeared on the scene before national professional associations did. In the less-established professions, the reverse pattern is typical. The early appearance of the training school underscores the importance of the cultivation of a knowledge base and the strategic innovative role of universities and the early teachers in linking knowledge to practice and creating a rationale for exclusive jurisdiction (Wilensky, 1964).

Where professionalization has gone farthest, the occupational association does not typically set up a training school; the schools usually promote an effective professional association. Those pushing for prescribed training continue to form a professional association. The association defines the tasks of the profession; how to raise the quality of recruits; redefining of function to include the use of less-technical people to perform the more routine, less involved tasks; and the management of internal and external threats. This last item would include internal conflict between the old-guard committed to the local establishment, and newcomers committed to practicing the work wherever it takes them. External conflict is primarily competition with neighboring professions for claims to exclusive competence. This conflict with neighboring occupations seems to go with later stages of professionalization.

Licensing

A separate area of study is licensing and certification. Two lessons may be inferred from the study of patterns in licensure and certification. The turn toward legal regulation may be an expedient of an occupation "on the make" where internal debate persuades members that it will enhance status or protect jobs; or it may be forced on an occupation by some clear and present danger where public debate persuades lawmakers to protect the layman. Legal certification and licensure protection is apparently not an integral part of any "natural history" of professionalism (Wilensky, 1964).

Code of Ethics

The last area of professional development is the establishment of a formal code of ethics. The code of ethics usually includes rules to eliminate the unqualified and unscrupulous; rules to reduce internal competition; and rules to protect clients and to emphasize the service ideal. In 10 of 13 established professions or professions in process, a code of ethics comes at the end of the professionalization process (Wilensky, 1964).

Newer and more marginal professions often adopt new titles, announce elaborate codes of ethics, or set up paper organizations on a national level long before an institutional and technical base has been formed. Also, the tactical and strategic situation of an occupation, old or new, may demand early licensure or certification, whatever the actual level of development of the technique, training, or association (Wilensky, 1964).

Relationship of a Profession to an Employer

Understanding the behavior of a professional in relation to type of organization is a prerequisite to understanding motivations for joining a professional association, and the use of such an association. There is a relationship in terms of outcomes between organizational values and subsequent actions taken to control entry, progression, rewards, and other forms of behavior (Timperley and Osbaldeston, 1975). It is at this stage that the relationship between a professional organization and an employing organization becomes important, for it brings into an employer's control system a further dimension; through the creation of a dependency upon the professional organization; through the use an employer might make of a professional organization's role and status system in his own career structures; and through a possible limitation of an employer's control over employees as a result of controls exercised by a professional organization on its members.

The above relationship between professional organizations and employing organizations is an extremely complex one, for it brings into play a large number of institutional and personal interactions and considerations. This is especially so with the newer "professions" where the possible ideal of employment as a professional is often subordinated to the reality of employment as an organizational member who happens to be a member of a professional organization. However, one of the characteristics of an occupational grouping attempting to gain professional status appears to be its attempt to increase the dependency of an employer on the occupational norms operated and reinforced by the formal occupational association.

Parsons (1954) notes the following about the legal profession: Its members are trained and interested in a distinctive part of the cultural tradition, having a fiduciary responsibility for its maintenance, development, and implementation. They are expected to provide a service to a client, within limits, without regard to immediate self-interest. The lawyer has a position of immediate independent responsibility so that he is neither a servant only of the client (though he represents that client's interests) nor of any other group, in the lawyer's case, of public authority.

Above all, the lawyer stands between two major aspects of social structure: Between public authority and its norms, and the private individual or group whose conduct or intentions may or may not be in accord with the law. The lawyer is schooled in the great tradition of the law. As a member of a great profession, he accepts responsibility for its integrity, and his whole position in society focuses that responsibility upon him.

Reiser (1988) notes the following about the medical profession: Why is it that people visit a physician, often a stranger to them, and are willing to reveal to this individual all details of their past and their present, and then to permit this individual to physically examine them? These actions are based on a concept of trust. We can put ourselves in the hands of medical strangers because we trust them. But why should we? Because we have become convinced that those by whom we call physicians and nurses live by a set of ethical standards that binds them to a commitment to helping us and not harming us. It is the public's perception that medicine seeks to subject its theories and practices to unbiased evaluation, which separates fact from belief, which is at the heart of its support of the enterprise.

Noel and Jose Parry (1977) developed an historical analysis of the formation of the British Medical Association from its beginnings in 1832 to the present. Their analysis notes, in particular, how the presence of the Association furthered the interests of the medical profession in England. For nearly 200 years, professionalism has been a powerful ideology of a growing section of the middle class. Translated into practical activity, it involves a quest by an occupational association for self-governing autonomy in which control is exercised collectively by the occupation over its practitioners and over occupational recruitment.

The professional searches for legitimacy from the state. He hopes that through legislation, the occupation may be granted some degree of monopoly over the services it provides and a recognition, in legal terms, of self-governing autonomy. The establishment of a register of qualified persons has been a typical way in which insiders can be distinguished from unqualified outsiders. Moreover, the qualifying examination, conducted in educational institutions controlled by the profession, has been used as the mechanism by which closure of the occupation is achieved (Parry and Parry, 1977).

The autonomy of the physician is legendary among professions. As noted by Parry, their professional history reflects an early concern with the development of the profession as an entity, and the inherent self-direction and self-regulation of an autonomous profession (Parry and Parry, 1977). In contrast, engineering is a profession in name only. Engineers, as professionals, have little of the autonomy of the physician.

The contrast between the two professions is also reflected in the respective publics served by each profession. For the physician, the public is, in general, the individual patient. The level of concern is at the individual level, with an independent provider/independent client relationship. The patient/practitioner relationship is codified, as it were, in the Hippocratic Oath and subsequent codes of ethics.

Engineers are typically employed by large organizations, with a somewhat abstract provider/customer relationship. Except for those engineers in independent private practice, the customer is typically the general public.

The Role of Legal Restraints

Professions search for legitimacy from the state. They hope that through legislation, the occupation may be granted some degree of monopoly over the services it provides and recognition in legal terms of self-governing autonomy (Parry and Parry, 1977). Autonomy, the quality or state of being independent, free, and self-directing is a key element in the definition of profession. For the professional, control over the content and the terms of work are self-directing his work.

The more self-directing an occupational group has become, the more likely a legal or political position of privilege has been obtained to protect it from encroachment by other occupations. This is the primary function of licensure (Freidson 1971). One of the crucial factors in physician's achieving of self-governing professionalism in England was that the state machinery for regulating and controlling medical care in the mid-19th century was weak. This lack of strength was still true in the early 1890's, at a time when the medical profession desired from the state a strengthening of protection from the competition of unqualified practitioners. Because the physician was well organized prior to the major entry of the state into the medical market place in 1911, their organized power as a profession was fundamental to securing an important measure of professional control over the state scheme. This control was guaranteed by state legislation and by administrative practices that grew under its umbrella (Parry and Parry, 1977).

Credentialing can occur through either licensing or certification. Licensure is a state function. It is defined as "the process by which an agency of government grants permission to an individual to engage in a given occupation upon finding that the applicant has attained the minimal degree of competence necessary to ensure that the public health, safety, and welfare will be reasonably protected" (Friedman, 1981). Licensure laws vary among professions and among states. Licensure laws pertaining to engineers exist in all 50 states, however licensure is not required, to practice as an engineer, except when an individual offers his services to the public as an "engineer" (Favoritti, 1980). This type of individualized engineering consultation is rare. Licensure in engineering is essentially "title protection".

Certification is a voluntary process. Nongovernmental agencies grant recognition of competence to an individual who has met certain predetermined qualifications (Freidson, 1971). Certification provides no legal protection for either the consumer or the practitioner (Favoritti, 1980). In 1977, the National Commission for Health Certifying Agencies (NCHCA) was chartered by the Department of Health and Human Resources as a voluntary body charged with developing standards for certifying groups. The standards ranged from the need for certification itself to the composition of organizations' governing boards. Issues that the NCHCA faced included the demand of third-party payers to reimburse only if a practitioner is credentialed, and the higher salaries asked by credentialed individuals.

Overshadowing all issues is a resolution to the question of whether credentialing in any form guaranteed quality and patient protection. Credentialing is heavily dependent on mechanisms for periodic recredentialing. Recredentialing, in turn, depends upon the continuing-education unit. William Turner of North Carolina State University, and several associates from both industry and academia proposed the continuing-education unit in 1968. The continuing-education unit is essentially a system of awarding credits for nonacademic credit courses. More than 1,200 colleges and 120 professional societies award continuing-education units. The continuing-education unit has been formalized through the National University Extension Association.

The continuing-education unit is defined as "ten contact hours" of participation in an organized continuing education activity under responsible sponsorship, capable direction, and qualified instructions (Patton, 1979). The continuing-education unit has been criticized as a public-relations gimmick designed to keep educators employed. Continuing-education unit programs may require examinations just as if they were degree courses. Other continuing-education programs award credit simply for chair-warming (Patton, 1979).

The Role of Professional Societies in the Professionalization Process

For nearly 200 years, occupational associations have sought self-governing autonomy in which control is exercised collectively over its practitioners and over occupational recruitment (Parry and Parry, 1977). Because the physician was well organized prior to the major entry of the state into the medical market place in England, the physician's organized power as a profession was fundamental to securing an important measure of professional control over the state scheme.

The role of the professional society in the professionalization process has been discussed in the work of Wilensky (1964). The professional society, through the traditional early influence of the academic community, establishes the knowledge base on which the profession is to develop.

In the Wilensky study, successful, established professions followed a developmental pattern where university training schools appeared before national professional associations. This pattern underscores the importance of the cultivation of a knowledge base. Teachers are the link between knowledge of practice and the creating of a rationale for exclusive jurisdiction. Where professionalization has gone farthest, the occupational association does not typically set up training schools; the schools usually promote an effective professional association.

Although the formal aims of professional associations may not emphasize collective bargaining as an activity, the individual member can and does use membership of, and qualifications obtained from, a professional body as a bargaining instrument in his relationship with his employer or potential employer. The development of a strong identity enables professional associations to obtain considerable influence over the personnel activities of the employer (Timperley and Osbaldeston, 1975).

As discussed earlier, university training schools appeared in the developmental history of the successful profession before professional associations did. Schools usually promote an effective professional association (Wilensky, 1964). Those individuals who push for prescribed training form a professional association. The association defines the tasks of the profession; how to raise the quality of recruits; redefining of function to include the use of less technical people to perform the more routine, less-involved tasks; and the management of internal and external threats.

Conclusion

In the Wilensky and the Timperley and Osbaldeston studies, status and education are identified. The educational system is the single most significant factor in determining the performance of the practicing professional. For example, the medical student is socialized to become a physician through the medical education system (Freidson, 1971). The educational background of members of an occupational association with professional aspirations is an important determinant of that association's status.

Education cultivates a knowledge base on which the knowledge to practice and exclusive jurisdiction of the profession is established. Knowledge and exclusive jurisdiction, in turn, enhance the status of the profession.

The early appearance of university training schools in the professionalization process underscores the importance of the cultivation of a knowledge base and the strategic innovative role of universities and the early teachers in linking knowledge to practice and creating a rationale for exclusive jurisdiction. Where the professionalization process has gone farthest, the occupational association typically does not set up a training school; the schools usually promote an effective professional association (Wilensky, 1964).

Legal certification and licensure protection is not a part of any natural developmental history of professionalism (Wilensky, 1964). However, much of a profession's strength is based on a legally supported monopoly over practice operating through a system of licensing. The mystique of a profession revolves around its ability to institutionalize legally its place in society (Illich, 1977).

Thomas J. O'Dea

Hemoxy, LLC
Shoreview, MN

This chapter concerns the advocacy of clinical engineering and the ethics associated with its practice. The bylaws of the American College of Clinical Engineering (ACCE) address both of these topics. For example, ACCE (Bauld, 1991) defines a clinical engineer as "A professional who supports and advances patient care by applying engineering and management skills to health care technology."

ACCE amplifies this definition in its seven-point code of ethics, as follows:

1. Prevention of injury in the clinical environment
2. Accurate representation of the clinical engineer's knowledge, level of responsibility, education, authority and experience
3. Revelation of conflict of interest
4. Protection of confidential information
5. Improvement of patient care delivery
6. Cost containment by technology utilization
7. Promotion of the profession of clinical engineering

This chapter will address the above points based on the knowledge of the author, a clinical engineer with 35 years of experience, and describes the relationship of these areas to ethics and advocacy.

Basis for Advocacy

The basis for advocacy is the perception that the clinical engineer, defined by the ACCE and the certification process, adds value to the equipment safety and technology functions frequently performed by various personnel in the health care environment. The justification of this perception forms the basis for advocacy, both within the medical technology community and to the public, using the experience of one average clinical engineer. The goal of improved patient care justifies efforts to preserve and to strengthen the profession. Whether the clinical engineering profession develops in influence and recognition depends, in part, on whether those in the profession are demonstrating and teaching other professionals in health care and the general public about the critical role that clinical engineering plays in health care.

The work of clinical engineers is often best appreciated in the long term, because many of their responsibilities entail strategic planning, systems development, training in the application of health care technologies, technology assessment and evaluation, health care technology management, and product development. Perhaps it is easier to explain the benefits of the work of biomedical equipment technicians (BMETs), whose main responsibility is to obtain immediate results in such areas as equipment repair and maintenance.

Clinical Engineering Expertise

Clinical engineers have unique expertise in medical device applications and are valuable to medical device technologies research and development efforts. Clinical engineers can start with an idea for a device and see that idea develop into prototypes, clinical trial models and finished products. An example of this is detailed in "A Novel Device for Measuring the Effect of Cholesterol on the Release of Oxygen from Red Blood Cells into Myocardial Tissue" (O'Dea et al., 2000). In this project, the author worked with a team to study the effects of cholesterol on the diffusion of oxygen through the red blood cell membrane. Clinical engineering expertise contributed to the creation of a device to measure the diffusion times for red blood cells by verifying the device's operation with laboratory results preparing a quality plan to satisfy existing regulations, and participating in clinical trials.

In addition to creating devices, existing devices must be introduced to patients by people knowledgeable in both engineering and the clinical environment. This requires adaptation to the physical environment, staff capabilities, and patient needs of an individual health care institution.

Patient Safety

Patient safety requires knowledgeable professionals in technical areas for the discovery, evaluation, and mitigation of patient risk. The author's work (O'Dea et al., 1998) on the interaction of infant warmers and bilirubin lights with the regulation of temperature of newborn infants is an example of an unexpected safety issue discovered during the ordinary duties of a clinical engineer. The nurses in the Neonatal Intensive Care Unit (NICU) experienced problems with using infant incubators in the servo-controlled temperature mode on some neonates. The manual mode triggered an audible alarm every few minutes, which added to the already high sound level in the NICU. In looking at the entire situation, interaction between the infant warmer and the bilirubin lights used simultaneously on low weight newborns prevented effective control of body temperature, since the uncontrolled energy delivered by the broad spectrum bilirubin lamps was significant compared to that delivered by the incubator. Once the cause of the problem was determined, operational changes in the simultaneous use of the two devices allowed effective care.

An example of combining the disciplines of clinical engineering and medical physics is quantification of patient skin radiation dose during neurointerventional procedures (O'Dea et al., 1999). This study determined the probability of patient skin injury due to radiation received during such procedures as cerebral angiograms and embolizations. Using the data from this study, a method of estimating the probability of patient injury was proposed, using fluoroscopy time and the number of digital angiographic images, both easily obtained from the radiographic equipment. Some neurointerventional procedures had a small likelihood of patient injury, and might be omitted from an elaborate monitoring program, while others had a higher likelihood of injury, and should be part of such a program. Another collaboration effort with a medical physicist yielded a quality control system for automated dosimetry and the estimation and mitigation of error (Li et al., 1999).

Engineering the Environment

Securing environmental conditions that contribute to a positive patient outcome through evaluation, specifications, design, and management is part of the practice of clinical engineering. The author demonstrated the way in which the clinical engineer can engineering the environment when he determined the isolation requirements of immunocompromised patients, assessed the ventilation system, and developed methods of measurement and practical solutions to balance isolation from spores against patient comfort and system efficiency (O'Dea, 1996).

The examples of how clinical engineering provides a safe patient environment have three characteristics in common:

1. They arose from conditions observed during the performance of ordinary clinical engineering duties.
2. They affected areas normally not mentioned in clinical engineering practice, i.e., facility engineering, radiology, and nursing. Collaboration with health care professionals in those areas is essential.
3. Resolution of the issues was not possible with standard repair or technology management methods. Solutions required in-depth study of the medical issues, engineering methods, and applications of practical hardware to safety.

These cases illustrate how clinical engineering has a unique and positive effect on safety in the health care setting.

Health Care Technology Management

The management of the health care institution is affected by applying clinical engineering principles to maintenance, performance verification, and the identification and adaptation of new technology. Demonstrating the role of clinical engineering in management, O'Dea and Marshall (1995) conducted a cost-saving study on the maintenance of sterilizers and operating room tables. They describe the steps taken to introduce in-house technology maintenance to an area previously served by outside contractors. The process

resulted not only in cost savings, but also in the re-engineering of a washer-sterilizer to be safely used as a pressure vessel. It also allowed the facility greater flexibility in purchasing operating room tables that surgeons wanted but had not been able to acquire due to lack of manufacturer support.

Simply repairing a medical device and placing it back in service without looking into the reasons for failure could result in a missed opportunity to modify a hospital-wide system or practice that routinely contributes to device failure. O'Dea et al. (1997) developed a verification procedure for video-endoscope systems. This work was done after we had discovered, while performing a routine repair, that performance verification was not done, that educational programs for residents were deficient, and cleaning procedures were inadequate. These issues led to increased cost and decreased reliability of technology systems, but management changes significantly decreased operating costs.

Advocacy plans must continue to stress that clinical engineers can analyze problems and synthesize solutions. For example, clinical engineers recommended using frequency domain multiplexing and carrying clinical local networks, terminals, main-frame wiring, and security video over the wideband TV distribution system, rather than recabling an entire building for data. By postponing this recabling for ten years, the useful life of existing technology was extended at significant savings to the hospital. Clinical engineers often have solved system problems such as interfacing research-oriented data gathering systems and existing clinical systems. Clinical engineers have designed four-catheter, 16-channel research cardiac electro-stimulation systems for use in the cardiac catheterization laboratory, enabling the hospital to offer more services to the community.

These examples clearly demonstrate the benefits of clinical engineers. Advocates must relate these examples, and others like them, to those in the health care business and to the general public.

ACCE Advocacy Committee

ACCE has formed an advocacy committee to assist members in educating the health care profession and the general public in the value of clinical engineering to patient care (see Chapter 130 for a detailed description of ACCE). Among the committee's current activities is the awarding of the annual clinical engineering advocacy awards in technical areas, management areas, and safety. Other committee work involves developing tools for the celebration of National Engineering Week, assisting displaced clinical engineers, and responding to those who mischaracterize the role or importance of clinical engineers. For example, if a hospital seeking a clinical engineer advertised in a journal but listed inappropriate qualifications, such as a two-year associate's degree requirement, the commit-

tee would respond to the hospital and the journal running the ad with the correct educational requirements for a clinical engineer: A four-year engineering degree. The committee also would provide guidance on actions to take when individuals more accurately described as biomedical engineering technicians inappropriately list themselves as clinical engineers.

Conclusion

The care of the patient is paramount, and the clinical engineer can create a safer and more competent environment for that care. Clinical engineers have achieved recognition and shown value by applying engineering and management skills to health care as previously described. Advocacy efforts through the ACCE Advocacy Committee continue to dispense information regarding the role that clinical engineers play in health care.

Health Care

The American College of Clinical Engineering (ACCE), which is committed to enhancing the profession of clinical engineering, is the only internationally recognized professional society for clinical engineers with members in the United States and around the world. Founded in 1990, ACCE has developed and promoted clinical engineering leadership, guidelines, recommendations, and advocacy efforts in a short time. Extensive membership benefits include the *ACCE News*, the foremost newsletter of clinical engineering in the world, and educational programs, including annual symposia, meetings, teleconference series, and advanced clinical engineering workshops (ACEWs). ACCE relies upon the strength of its members, who ensure a vibrant voice for clinical engineering worldwide through participation on boards, committees, and special programs. The ACCE recognizes and rewards those who have excelled in the pursuit of clinical engineering excellence.

Establishment and History

The American College of Clinical Engineering was established in 1990 following two years of planning that included dialogue among colleagues in conjunction with other society meetings, phone calls, faxes, and planned group discussions, with the sole purpose of forming such a society. As with any organizational beginnings, there were growing pains that included some successes and some failures. Overall, the mission of the ACCE has been maintained, and the clinical engineering profession has matured more during ACCE's tenure than before it existed.

Rationale for Establishment

During the late 1980s, it became apparent through existing professional engineering organizations (such as the Institute of Electrical and Electronics Engineers (IEEE), Engineering in Medicine and Biology Society (EMBS), and the Association for the Advancement of Medical Instrumentation (AAMI)) that no single organization was dedicated exclusively to the promotion and support of clinical engineering. Many clinical engineers desired such an organization. In 1988, a session at the Annual Meeting and Exposition of AAMI in St. Louis, Missouri, entitled "Do We Need Another Professional Engineering Society?" convened members of IEEE, EMBS, AAMI, and others to discuss their current mission and how they would promote and develop the clinical engineering profession. Throughout the discussion, it became apparent that no organization had the resources or dedication to promote the profession of clinical engineering while maintaining their own mission and breadth of membership, and that the clinical engineering profession sorely needed sufficient representation. One astute session attendee pointed this out during the question-and-answer session and suggested that another society might be needed. The wheels were set into motion and the rest is history.

Over the course of the following year, many clinical engineers furthered the conversation on the need for such an organization, through ad hoc phone calls, letters, and meetings, both nationally and internationally. Many experts in the field discussed the topic and pursued the development of the organizational name, mission, bylaws, and application for formation. The important question to address was where this new society would fit in the current realm of professional and trade societies. Many of these groups crossed into the clinical engineering realm, but none was solely dedicated. There was much discussion as to the title of the organization, as many were sensitive to the international component and ways in which the formation of this society would play well into international support. Some suggested names included the North American Clinical Engineering Society, the Hospital Engineering Society, the Health Care Engineering Society, and the International College of Clinical Engineering.

After initial discussions that created the vision for ACCE, significant work remained to be done before the society could form. Other interested clinical engineers were invited to assist in crafting documents to present at the 1989 AAMI meeting. This presentation consisted of the core group of founders and other supporters. This group provided the interest and sustenance to continue with this endeavor. In February of 1990, paperwork was submitted to the state of Washington to form the American College of Clinical Engineering.

The First Clinical Engineering Organization

ACCE was the first organization to be dedicated solely to the field of clinical engineering, both nationally and internationally. At its inception, many requests for advocacy, support, and professional development were received, and the necessity to streamline and further develop the activities of the charter members became apparent. The newly approved board of directors and other charter members of the ACCE did not take the job lightly. The first step in ensuring the success was to develop a mission and definition of clinical engineering.

Exclusivity

The founding members of the ACCE were clear as to the purpose and future support. Within the clinical engineering domain there are many functions, all of which benefit the profession as a whole. The purpose of this group was to promote those individuals who fell within the definition of "clinical engineer" (Bauld, 1991). The ACCE definition, which most clinical engineering organizations worldwide now accept, is the following:

A clinical engineer is a professional who supports and advances patient care by applying engineering and managerial skills to health care technology.

While ACCE must remain focused on benefiting its members, it desires to support (to the extent possible) other professionals who work closely with clinical engineers. Such individuals include biomedical engineering and equipment technicians (BMETs). Over the years, there have been many discussions—some friendly, some not—regarding the role of ACCE and its support of the BMET. Currently, there is no national organization of BMETs in the United States. Some perceived the ACCE as an organization that neither wanted BMET involvement nor recognized the BMET's role with respect to the clinical engineering profession. Some ACCE members want an organization focused on clinical engineers only and others want to support BMETs as they work so closely with clinical engineers and share many of their goals. The ACCE Board of Directors has always striven for middle ground. While the need for support of the BMET group is keenly felt by most BMETs, ACCE must stay true to its mission. The ACCE is not a large enough organization, nor does it have the resources, to take on the complete support of the BMET in a national setting. Their requirements and needs are different. BMETs are encouraged to join ACCE and, depending upon their qualifications, can belong at one of many different levels. ACCE promotes the clinical engineering profession through educational opportunities in which BMETs can attend, and even lead. The ACCE Board of Directors would entertain the concept of assisting a group of BMETs in the development of its own professional society and determining how ACCE and BMETs can work more closely together to further the promotion of clinical engineering and the mission of ACCE.

Growing Pains

The early years of ACCE were indeed a struggle. Cash flow was tight, and the request for professional advancement was high, both nationally and internationally. There was much antagonism from other societies who treaded into the clinical engineering domain, such as AAMI, the American Society for Healthcare Engineering (ASHE), and IEEE EMBS. The ACCE board of directors and other members who crossed over into those other soci-

eties worked hard to explain the mission of ACCE and that it was exclusive of the roles that these societies supported in clinical engineering. The other societies simply could not provide sufficient dedicated clinical engineering representation.

Charter Members

Many dedicated clinical engineering professionals deserve credit for the formation of the American College of Clinical Engineering (Table 130-1). Without their support of their profession and their contribution of time and resources, ACCE never would have been formed and would not have survived the early years. The list of charter members who founded the organization and showed support by joining during the first year of existence (1990) is shown below (ACCE News, 1991). All should be recognized for their aggressive support in seeing the establishment of the ACCE through to fruition.

Mission

The first board of directors and other founding members worked diligently to develop a mission of the ACCE that was the purpose for establishing ACCE in the first place. It was important that the mission kept the focus of a *clinical engineering only* organization while promoting the field of health care technology management, important components of which are medical device inspection, maintenance and repair, which constitute the bulk of BMET responsibilities.

The following four points were approved and have remained the sole mission of the ACCE since inception:

1. To establish a standard of competence and to promote excellence in clinical engineering practice
2. To promote safe and effective application of science and technology in patient care
3. To define the body of knowledge on which the profession is based
4. To represent the professional interests of clinical engineers

Examples of fulfilling the mission can be seen throughout the organization and will be discussed in detail within this chapter

Code of Ethics

During the formative years, the requirement for a professional code of ethics was determined to be necessary, to establish parameters of professional duties and to explain what ACCE was trying to achieve. This is different from the mission and provides a means for the members to determine the ways in which their work affects the promotion and application of the profession. Following is the Code of Ethics.

As a member of the American College of Clinical Engineering, I subscribe to the established Code of Ethics in that I will:

- Strive to prevent a person from being placed at risk of injury due to dangerous or defective devices or procedures
- Accurately represent my level of responsibility, authority, experience, knowledge, and education
- Reveal any conflicts of interest that may affect information provided or received
- Protect the confidentiality of information from any source
- Work towards improving the delivery of health care to all who need it
- Work towards the containment of costs by the better utilization of technology
- Promote the profession of clinical engineering

Membership Benefits

The available membership benefits have changed throughout the years to reflect the changing profession. In general, ACCE is building a strong, credible, dynamic, and flexible profession. ACCE membership provides advantages that will enhance a clinical engineering career now and for many years to come. Benefits include the following:

- Access to a network of experts and peers
- Representation of interests to legislators and regulatory agencies
- Instant access to valuable technical information via the ACCE web site at <http://www.acenet.org>
- Up-to-date information (via the ACCE newsletter) that is so critically needed in the rapidly changing health care environment

- Engaging in special projects from time to time, such as advanced clinical engineering workshops
- Providing opportunities to share expertise with other professionals

Marketing Relationship

In 1996, the ACCE Board of Directors entered into a marketing venture with Morse Medical. Wayne Morse, CCE, president of Morse Medical and founding member of the ACCE, assisted ACCE in marketing and promoting ACCE products. The list below indicates products and their description that were available throughout this arrangement, although some may no longer exist. For further information on products that are currently available, please refer to the ACCE website at <http://www.acenet.org>.

Products

- *Lapel Pin*: Attractive pin is designed for ACCE members and is suitable for use with a lab coat or suit jacket.
- *Logo*: The ACCE logo (Figure 130-1) can be added to apparel such as a hat or shirt.
- *Clinical Engineer Definition Plaque*: An 8" x 12" wooden plaque displaying the ACCE definition of a clinical engineer for an office or department to promote the profession.
- *Code of Ethics Plaque*: An 8" x 12" wooden plaque displaying the ACCE Code of Ethics for an office or department to promote the profession.
- *Membership Directory*: A current annual directory that is a very valuable resource and reference document. In these pages are the names, addresses, phone and fax numbers, and e-mail addresses of the finest group of clinical and biomedical engineers in the world.
- *Guidelines for Medical Equipment Donation*: In an attempt to address problems with donating equipment, the ACCE has developed guidelines to improve the effectiveness of donations of medical equipment.
- *CE Certification Study Guide*: Based upon the International Certification Commission (ICC) and AAMI program, this study guide offers a quick and easy self-evaluation for those professionals who plan to take the CE certification exam.
- *Teleconference Audiocassette Tapes* (including handouts): The audiocassette tape and handouts from some of the best in the ACCE teleconference series.
- *ACCE Brochures*: Brochures developed for the membership include the following: *ACCE: The American College of Clinical Engineering, What is a Clinical Engineer?*, and *Providing Clinical Engineering Support to the Countries Worldwide*, from the International Committee.
- *ACCE News*: A bimonthly publication and the foremost newsletter of clinical engineering in the world dedicated to promoting the activities of ACCE and its members.
- *ACCE website*: Access to a wealth of information regarding ACCE through the ACCE web site. Members-only access is under development.

Programs

- The educational teleconference series is held each year, with a variety of topics presented once per month. Members receive a discount and the ability to have multiple participants from one site.
- Advanced clinical engineering and health technology workshops are held at various times throughout the world. The goal is to improve the skills and knowledge of those who are involved in medical technology management and facilities planning.
- INFRATECH was created in 1999. It is a listserv sponsored by World Health Organization (WHO), hosted by the Pan American Health Organization (PAHO), and coordinated by ACCE—an Internet discussion group for the exchange of information on health care infrastructure and technology for health services.
- ACCE symposia are held once a year dedicated to a topic that is essential to the future of clinical engineering.
- ACCE works with other societies and conferences such as AAMI, ASHE, and HealthTech to develop programs that promote the profession of clinical engineering. Members are often provided discounts to attend these educational meetings. ACCE is always looking to broaden the interaction with other societies and conferences.

Development

ACCE has been successful since its inception in 1990 in fulfilling the mission set forth by the founding members. In order to see the progress of the organization, the complete assessment and overview of all the ACCE activities must be taken into account. Presented here, however, is a brief summary of all activities held since establishment, thus providing a key into the development of the profession of clinical engineering and the success of ACCE.

Highlights of 10 Years

- *Mission*: The first clinical engineering only organizational mission was mentioned earlier in full. It is an essential developmental step when trying to establish any organization and provides direction to the founding group and future members.
- *Definition of Clinical Engineer*: Complementing the mission (and also mentioned earlier), this helped to define the profession and the membership of ACCE. It has been applicable throughout the history of ACCE.
- *Code of Ethics*: Addressing the need for professional liability (and mentioned earlier), this code has helped to formulate ways in which ACCE members should carry out the mission of ACCE.
- *Vision 2000*: Begun in 1995, this was ACCE's process to review the current and future environment of health care and develop strategies, objectives, and specific initiatives that will prepare our membership for the changes that continue to occur at a rapid pace.
- *PACE Initiative*: This name stood for Preparing ACCE for Cost Effectiveness and took place during the Vision2000 project. It served as a guide for the college. There were seven initiatives under the PACE banner (Bauld and Judd, 1995).

			Steve Wixson

- **1996 FDA GMP Regulation Response:** Drafted by current ACCE president Thomas J. Bauld, Ph.D., it voiced the concern of the ACCE membership on the proposed regulations (Bauld, 1996).
- **1998 FDA ANPR Response:** Drafted by current ACCE president Frank Painter, CCE it discussed the expertise of ACCE and its members (Painter, 1998).
- **Teleconference Series:** An annual series of monthly, hour-long presentations covering topics of interest to ACCE members.
- **ACCE News:** A bimonthly publication and the foremost newsletter of clinical engineering in the world dedicated to promoting the activities of ACCE and its members
- **Advocacy Awards:** Allows ACCE to recognize members and nonmembers for professional achievement and professional development.
- **ACEW:** Advanced Clinical Engineering Workshops are international educational opportunities where ACCE provides faculty and shares expertise throughout the world. Workshops are often sponsored by World Health Organization (WHO) or the Pan American Health Organization (PAHO).
- **Membership Surveys:** Designed to take the pulse of the membership to ensure that the organization is meeting the needs of the membership and to plan further projects.
- **Web Site:** An Internet-based method to communicate to the membership. It allows members and nonmembers the opportunity to learn more about ACCE, the membership, and activities.
- **White Papers:** Topics of interest to the clinical engineering community and beyond are explored by an ad hoc task force developed by the board of Directors. The white paper developed in 2001 was on patient safety.
- **Certification:** In 1999, the AAMI board of directors approved the suspension of the current Certified Clinical Engineer (CCE) program. ACCE has worked diligently to put the program back into place in a much better format.
- **Joint Educational Activities:** ACCE has worked throughout the years with other groups such as ASHE, AAMI, HealthTech, and others to develop educational sessions geared towards clinical engineering. Expansion of the societies with which ACCE interacts is always encouraged.
- **BMET Task Force:** Formed originally in 1997 because AAMI dissolved the Society for Biomedical Equipment Technicians (SBET), the group explores ways in which ACCE can assist our fellow members of the health care technology community. These activities are ongoing.
- **AHA Telemetry Task Force:** Many ACCE members were asked to serve on the AHA telemetry task force to define the telemetry issues, to determine current and projected needs, and to develop educational materials. All of this was done in response to the digital-television technology shift and the subsequent allocation of broadcast frequencies by the U.S. government (Campbell, 1998).
- **Symposia:** Begun in 1998, the annual educational meeting discusses topics of interest to ACCE members in particular the future of clinical engineering and the profession.

Membership

Categories

There are five membership categories as of the approved bylaws in August 2002: Individual, Fellow, Emeritus, Associate, and Candidate. Each has different criteria for approval by the Membership Committee and the ACCE Board of Directors.

Individual

A person who has demonstrated evidence of professional practice of engineering in a clinical environment for at least three (3) years, and who meets one or more of the following three conditions:

1. Possession of a baccalaureate degree in an engineering discipline or engineering technology from an accredited college or university (or foreign equivalent)
2. Certification as a Clinical Engineer (CCE), by the International Certification Commission for Clinical Engineering and Biomedical Technology
3. By recommendation of the Membership Committee in recognition of exceptional contributions, consistent with criteria established by the board, to the profession of clinical engineering.

Fellow

An Individual member may be advanced to Fellow status in recognition of distinguished service to the profession or achievement in the field of clinical engineering. The member must have been active in the College business over a minimum period of three years.

Emeritus

An Individual or Fellow member may be advanced to Emeritus status:

- In recognition of distinguished service to the profession or achievement in the field of clinical engineering
- After at least five continuous years membership in good standing in the College, and upon reaching the age of 62 and retirement from full-time employment in the profession of clinical engineering.

Associate

An individual committed to the mission of this organization, who has demonstrated a contribution to the advancement of the clinical engineering profession, and meets other requirements established by the board, but does not meet the other conditions required for Individual membership.

Candidate

An individual who is interested in the purpose of this organization and who meets one of the following two conditions:

1. Current enrollment at least half-time in an accredited baccalaureate or graduate program in engineering, engineering technology, or related course of study; or
2. Completing the three-year clinical experience requirement for Individual membership after receiving a baccalaureate or graduate engineering degree.

Renewal

Membership renewal occurs on an annual basis in conjunction with the calendar and fiscal year of ACCE. Initial renewal notices are sent in November with reminders in January and February. March 1 is the deadline and the membership roster reflects the current membership at that time. Future mailings and notifications are dependent upon the current membership roster. Renewal costs are set by the board and have remained reasonable in comparison to other professional societies since inception. Renewal and dues costs for 2002 were \$60 for Individual, Fellow, and Associate members, \$30 for Candidate members, and \$0 for Emeritus members.

Board

Responsibility for management of the College is vested in the board, which consists of 10 members: The president, the president elect, the vice president, the secretary, the treasurer, the immediate past president, and four members-at-large. Board members will be elected as specified in the bylaws. Each member of the board is entitled to one vote. Further explanation of the individual officer duties, election process, and terms of office can be found in the bylaws section in this chapter. Board meetings are held at least quarterly, usually bimonthly. They are conducted via conference call with items being distributed by e-mail. On an annual basis, there is one meeting conducted live, usually in conjunction with the annual membership meeting.

The executive board consists of the president, president elect, vice president, secretary, treasurer, and immediate past president. Meetings are held via conference call on a monthly basis to ensure progress continues on various ACCE activities and to develop the agenda for the bimonthly board meetings.

Committees

An organization with ACCE's focus and breadth could not survive without the help of committees. Many ACCE members have participated on committees, and their assistance is always greatly appreciated. Further specifics on the terms and conditions for committees can be found in the bylaws. There are two types of committees as specified in the bylaws: Standing and general.

Standing Committees

The current standing committees include the Membership and Nominating Committees. Standing committee members must be members of the College in good standing, at the membership level of Individual, Fellow, or Emeritus.

Membership Committee

The Membership Committee reviews all applications for new memberships and membership changes to the College and makes recommendations to the board regarding the qualifications of the applicants. It also establishes and maintains criteria and procedures for admission and resignation of members of the College, in addition to developing and recommending application processes and forms. The president with the approval of the board, appoints a committee chair. The committee chair appoints four committee members with the approval of the president.

Nominating Committee

The Nominating Committee prepares a list of nominees for all offices that expire the following August 1. Only one nominee will be listed for each office, as others will be solicited at the annual membership meeting. The committee should list only nominees who are willing to serve if elected and to attend board meetings. The immediate past president serves as chair of the Nominating Committee. The president will appoint four committee members with the approval of the board.

General Committees

The board may create any other standing and special committees as may be necessary to carry out the business of the College. Committee chairs must be Individual, Fellow, or Emeritus members. Any member or nonmember may serve as a Committee member. The president will appoint committee chairs with the approval of the board. The committee chair will appoint members to the committee. All appointments expire at the end of the chair's term, but committee members may be re-appointed for an unlimited number of consecutive terms. The president will appoint a board member to serve as a nonvoting liaison member of each general committee. The president may appoint himself to serve in this role. Committees have included: Advocacy, Education, International, Government Relations, Inter-Society, Vision2000, and Clinical Engineering Certification.

Task Forces

In addition to formal, general committees, the board has requested members to assist with other projects that revolved around society relations or the development of white papers.

These have included intersociety relations, the BMET Task Force, and the Medical Error Task Force.

Demographics

ACCE membership has been diverse from the start. The strength of ACCE has been due to the support received throughout the United States and the world. This also provides a challenge to the board to develop programs and leadership that can reach the distance. As of August 2002 there are 189 current paid members: 158 Individual, 5 Fellow, 2 Emeritus, 18 Associate, and 6 Candidate. The breakdown of membership categories over the years is shown in Table 130-2.

Over the years the ACCE membership has represented 36 states plus the District of Columbia and Puerto Rico and 23 countries including: Albania, Bermuda, Brazil, Canada, Columbia, Denmark, Egypt, Germany, India, Italy, Kuwait, Malaysia, Mexico, Moldova, Nigeria, Pakistan, Poland, Saudi Arabia, Switzerland, Ukraine, the United Arab Emirates, the United Kingdom, and Venezuela. ACCE always continues to work in fostering national and international clinical engineering as reflected in the membership demographics.

Surveys

Throughout the years, the board has wanted to determine the best path for the organization and membership. This is often accomplished by taking a survey of the membership that allows member feedback and provides guidelines that ACCE leadership can concentrate resources. Questions asked include future focus as well as an evaluation of the current focus. The board reviews the results and dispenses activities to individual members or committee chairs to implement. Critical items are added to the board agenda for continual follow-up.

1995 Survey

There was a 50% response of the active membership. The scale was from 1–5, with 5 noting that the item was of “vital importance to the profession and of continued professional growth of the member.” The following activities indicated strong support: *ACCE News* (average rating 3.9); Vision 2000 Project (average rating 3.8); advocacy of the profession (average rating 3.6); collaboration with other organizations (average rating 3.3); annual awards program (tie, average rating 3.1); and audio conference series (tie, average rating 3.1). The membership also suggested holding the annual membership meeting in conjunction with the AAMI meeting (Brody, 1996).

2001 Survey

Sixty-five members responded. A large proportion of them were Individual members. All ACCE benefits were rated as highly valued, except for clothing, which was also rated low for knowledge of existence. The board will work closely to promote this benefit. The preferred methods of communication were e-mail and web site access. Members felt that collaboration with other societies (including local BMET societies) was important. Comments included a concern for web site updating, improving advocacy efforts, and certification. Volunteers were solicited, and their names were forwarded to the appropriate committees (Zambuto, 2002).

Bylaws

The Bylaws for the American College of Clinical Engineering were established in 1990. They serve as an overall guide for the organization and membership on the way in which the society is managed carried forth. The membership has approved revisions. The version included within this chapter was approved the ACCE membership and board of directors in August 2002.

Table 130-2 ACCE members by membership categories

Year	Individual	Fellow	Emeritus	Associate	Candidate
1989	4				
1990	45	3*			
1991	26	2*			
1992	8				
1993	9				
1994	8			7	
1995	8			2	
1996	11				2
1997	25			5	2
1998	16			10	1
1999	15			6	1
2000	13			7	5
2001	16			2	2
2002†	7		2*	1	3
TOTAL	211	5	2	31	16

*Please note that this table shows a combination of the year joined and the membership category, which may have been upgraded throughout the years.

†2002 is a partial-year listing.

Bylaws

Article I: NAME

The name of this non-profit organization will be “American College of Clinical Engineering,” hereinafter referred to as the “College.” The College will also be known by the abbreviation “ACCE.”

Article II: PURPOSE

1. To *establish* a standard of competence and to promote excellence in Clinical Engineering practice.
2. To *promote* safe and effective application of Science and Technology to patient care.
3. To *define* the body of knowledge on which the profession is based.
4. To *represent* the professional interests of Clinical Engineers.

Article III: MEMBERSHIP

There shall be five (5) classifications of membership, as follows:

Individual

A person demonstrating evidence of professional practice of engineering in a clinical environment for at least three (3) years, and meeting one or more of the following three conditions:

- Possession of a Baccalaureate degree in an Engineering discipline or Engineering Technology from an accredited College or University; (or Foreign equivalent); or
- Certification as a Clinical Engineer (CCE), by the International Certification Commission for Clinical Engineering and Biomedical Technology; or
- By recommendation of the Membership Committee in recognition of exceptional contributions, consistent with criteria established by the Board, to the profession of Clinical Engineering.

Fellow

An Individual member may be advanced to a Fellow status in recognition of distinguished service to the profession or achievement in the field of Clinical Engineering. The member must be active in the College business over a minimum period of three years.

Emeritus

An Individual or Fellow member may be advanced to Emeritus status

- In recognition of distinguished service to the profession or achievement in the field of Clinical Engineering; and
- After at least five continuous years membership in good standing in the College; and
- Upon member’s reaching age of 62 and retirement from full time employment in the profession of Clinical Engineering.

Associate

An individual committed to the mission of this organization, who has demonstrated a contribution to the advancement of the clinical engineering profession, and meets other requirements established by the Board, but does not meet the other conditions required for Individual membership.

Candidate

An individual interested in the purpose of this organization and meeting one of the following two conditions:

- Current enrollment at least half-time in an accredited baccalaureate or graduate program in engineering, engineering technology, or related course of study; or
- Completing the three-year clinical experience requirement for Individual membership after receiving a baccalaureate or graduate engineering degree.

5. Only Individual, Fellow, and Emeritus members are entitled to vote on matters presented to the College membership.

Article IV: BOARD

Responsibility for management of the College is vested in the Board, which consists of ten (10) members: The President, the President Elect, the Vice President, the Secretary, the Treasurer, the Immediate Past President, and four Members-at-Large. Board Members will be elected as specified in these Bylaws. Each member of the Board is entitled to one (1) vote.

6. Officers:

Officers are elected from the Individual and Fellow membership.

President

The President presides at all meetings of the College and the Board. The President is responsible for carrying out all orders and resolutions.

President Elect

The President Elect performs all duties of the President whenever the President is absent or otherwise unable to perform these duties. The President Elect will oversee the Member Services and Education functions including implementation of ongoing strategic objectives approved by the Board in these areas. The President Elect will perform other duties as requested by the President of the Board. After completing a term as President Elect, the President Elect shall become the

President, unless the President is elected for a second term. In such a case, the President Elect is eligible to serve an additional term as President Elect. In the event that the President Elect can not assume the role of President at the end of his or her term as President Elect, a new President shall be elected from current members of the Board. The Immediate Past President and officers, other than the President, are eligible for this election.

Vice President

The Vice President will oversee the Marketing/Advocacy and Strategic Alliances functions including implementation of ongoing strategic objectives approved by the Board in these areas. The Vice President will perform other duties as requested by the President or the Board.

Secretary

The Secretary is responsible for keeping minutes of all membership and Board meetings. The Secretary also coordinates the membership roster, and is responsible for all notices sent to the College's membership and Board.

Treasurer

The Treasurer of the College is responsible for the receipt, disbursement, and record keeping for all of the College's funds. The Treasurer will present an accounting of income, expenditures, and fund balances at all Board meetings and the Annual Membership Meeting(s). The Treasurer will disburse funds only in accordance with policies established by the Board. The Treasurer will present an annual written summary of the College's financial status to the membership.

Immediate Past President

The President will become the Immediate Past President upon completion of the President's term of office. The Immediate Past President chairs the Nominating Committee.

7. Members-at-Large

Four (4) Members-at-Large are elected from the Individual and Fellow membership. Each Member-at-Large serves a two-year term. The Nominating Committee will try to ensure that in any one election only 2 Members-at-Large positions are being filled. Vacancies and special exceptions will be reviewed and approved by the Board.

8. Vacancies

Any office declared vacant by the Board, whether through resignation, death, disability, or inactivity, will be filled by the Board through appointment. New appointments will fill the term being vacated.

If the office of Immediate Past President becomes vacant, the Board will appoint a new Immediate Past President from among the former President's of the College. If none of the former Presidents are willing to serve, and appointment will be made from among the Fellows of the College.

All Board Members are expected to attend meetings regularly. The Board will assume that a Board Member has vacated his office if the Board Member misses two consecutive meetings without cause (as determined by the Board).

9. Quorum for Business

A. A majority of Board Members must be represented at a meeting to conduct business. Board Members may be represented either through actual presence at a meeting, through a telephone connection, through a proxy assigned to another Board Member, or through an absentee ballot must contain either an actual, a facsimile signature, or an e-mail from the Board Member. The validity of a proxy or absentee ballot will be determined by the officer presiding at the meeting.

B. A simple majority of the Board Members represented at the meeting is required to approve motions.

C. Emergency actions may be taken by the President whenever necessary to protect the assets or reputation of the College. If this becomes necessary, the President must consult with as many other Board members as practical before taking such emergency action. After such action is taken, the President must notify all Board members within five days. Transmission of a facsimile message or e-mail will be considered adequate notification under the provisions of this section.

10. Corporate Representative

The Board will designate a resident of the State of Washington to be its Corporate Representative within that state, to fulfill all the legal obligations required by that state. The Corporate Representative may hold another office in the College. The Corporate Representative is not a member of the Board (except by virtue of any other office held by that person), and has no responsibility for the governance of the College.

Article V: ELIGIBILITY AND TENURE OF OFFICERS

- Officers and Members-at-Large must be members of the College in good standing at the membership level of Individual or Fellow.
- No officer or Member-at-Large may hold more than one office at a time.
- The President, President Elect, and Vice President will serve for a one-year term of office.
- The Secretary and Treasurer will serve for a two-year term of office.
- All Members-at-Large will serve for a two-year term of office.
- The President, President Elect, and Vice President may serve two consecutive terms if elected for the office again.
- The Secretary and Treasurer may serve two consecutive terms.
- Member-at-Large may serve two consecutive terms.
- A partial Term of Office assumed by appointment of the Board will not be considered a term under the provisions of this article.
- The Term of Office of an elected officer or Member-at-Large begins on August 1 or 15 days after the closing date of the election, whichever is later. Closing date occurs by Board vote at the first Board Meeting after elections.

Article VI: VOTING

- Each Individual, Fellow, and Emeritus member in good standing is entitled to one (1) vote on any business coming before meetings of the College, and in elections.
- Votes may be cast in person, by written proxy, or by absentee ballot. The Board will establish policies to assure the validity of proxies or absentee ballots.
- One-fifth (1/5) of the total number of Individual, Fellow, and Emeritus members in good standing must be represented at a meeting in order to conduct official business. Members may be represented whether through actual presence at a meeting, through a proxy assigned to another member, or through an absentee ballot presented to either the President or Secretary. A proxy or absentee ballot must contain a signature (either actual or facsimile) or an e-mail of the Member. The validity of a proxy or absentee ballot will be determined by the officer presiding at the meeting.
- A simple majority of those voting is required to approve motions.
- Elections are conducted as required to approve motions.

Article VII: FISCAL CONTROL

- The Board controls all fiscal matters. Its actions are subject to review by the College membership.
- The fiscal year will be the calendar year.
- Dues are set annually by the Board, at a level consistent with an annual budget of expenditures and income, as well as other policies adopted by the Board.
- The Board will establish a membership year consistent with the fiscal objectives of the College.

Article VIII: MEETINGS

- An Annual Membership Meeting will be held during April, May, or June.
- Board meetings will be held at least quarterly.
- Special meetings of the Board can be called by the President, or upon written request of three members of the Board.
- Notification of all Board meetings will be made by the Secretary at least 15 days prior to the meeting, either by mail, telephone, facsimile transmission, or e-mail.
- Special meetings of the College may be called by the President or upon written request of at least one-fifth (1/5) of the voting members.
- Written notification of the Annual Membership Meeting and any Special Meetings must be mailed to the membership at least thirty (30) days prior to the meeting date.
- Parliamentary procedures to be followed in business meetings of the College, its Board, and its committee's will be those specified in "Robert's Rules of Order, Revised".

Article IX: COMMITTEES

1. Standing Committees

The Membership and Nominating Committees will be standing committees. Standing committee members must be members of the College in good standing at the membership level of Individual, Fellow, or Emeritus.

Membership Committee

The Membership Committee will review all applications for membership to the College, and make recommendations to the Board regarding the qualifications of the applicants. The Membership Committee will also review all applications made by College members for a change in their membership category and will make recommendations to the Board regarding the applicant's qualification for the applied-for category. College members may apply for a change in member category from:

- Candidate to Associate or Individual
- Associate to Individual
- Individual to Fellow or Emeritus
- Fellow to Emeritus

The committee chair will be appointed by the President, with the approval of the Board, for a two-year term. Four committee members will also be appointed by the committee chair, with the approval of the President, for staggered two-year terms. The Committee chair and the committee members may serve no more than two consecutive terms.

The Membership Committee will establish and maintain criteria and procedures for admission and resignation of members of the College in accordance with these Bylaws.

Upon recommendation by the Membership committee, applications for admission to the College will be forwarded to the Board for review and final approval. Upon acceptance by the Board, an applicant will become a member.

The Membership Committee considers and recommends to the Board candidates for elevation to Fellow status from among those Individual members who apply and who have held active membership in the College and professionally contributed to the College function for at least three years. Upon approval by the Board, a candidate will be elevated to Fellow status.

Nominating Committee

The Immediate Past President serves as Chair of the Nominating Committee. Four committee members will also be appointed by the President, with the approval of the Board, for a one-year term. These appointments will be made no later than January 1 each year. No more than one (1) member of the Nominating Committee, in addition to the Nominating Committee Chair, may be a member of the incumbent Board.

The Nominating Committee prepares a list of nominees for all offices which expire the following August 1. Only one nominee will be listed for each office.

The committee will only list nominees willing to serve if elected and to attend Board meetings.

The Nominating Committee will report on its recommendations to the Board at a Board meeting to be held in February or March. The Board will review this report. Upon acceptance of the report, the nominees will be listed on the ballot as candidates for office. This list of candidates will be sent to the College membership with the notice of the Annual Membership Meeting.

At the Annual Membership Meeting, the floor will be opened for additional nominations. The Nominating Committee will confirm that any person nominated from the floor is eligible for office, and is willing to serve if elected and attend Board meetings. Upon confirmation, these nominees will be added to the ballot.

The Secretary will send election ballots to all Individual, Fellow, and Emeritus members no later than twenty-one (21) days after the Annual Membership Meeting. Members will be allowed fifteen (15) days after the mailing of the ballots to return them. The Secretary will count the ballots and notify the Board and all candidates of the results within fifteen (15) days after the closing date of the election.

Elected candidates will assume office on August 1 or 15 days after the closing date of the election, whichever is later. Closing date occurs by Board vote at the first Board Meeting held after elections.

2. General Committees

- The Board may create any other standing and special committees as may be necessary to carry on the business of the College. Committee chairs must be Individual, Fellow, or Emeritus members. Any member or non-member may serve as a Committee member.
- The committee chair will be appointed by the President, with the approval of the Board. A chair will serve for one (1) year and may serve no more than five consecutive terms.
- The committee chair will appoint members to the committee. All appointments expire at the end of the chair's term, but committee members may be re-appointed for an unlimited number of consecutive terms.
- The President will appoint a Board member to serve as a non-voting liaison member of each general committee. The President may appoint himself to serve in this role.

Article X: AMENDMENTS

- Amendments may be proposed by any Board member, or by a written petition submitted by at least three Individual, Fellow, Emeritus members.
- All proposed amendments to these Bylaws will be reviewed by the Board. Amendments proposed by Board members will be submitted to the membership only upon approval by the Board. Amendments submitted by written petition of the membership must be submitted to the membership, regardless of the Board's recommendation, unless the petitioners withdraw their proposed amendment.
- All proposed amendments will be sent to the membership with the Board's recommendations.
- A ballot containing the entire text of the proposed amendment will be sent to the membership by the Secretary no later than thirty (30) days after the Board meeting at which the amendment was considered. Members will have thirty (30) days after the mailing of the ballots to return them. An amendment will be adopted only if a majority of the total number of Individual, Fellow, or Emeritus members of the College in good standing approve.
- The Secretary will promptly notify the Board and the membership of the voting results.

Article XI: INUREMENT AND DISSOLUTION

- The assets of this organization will never inure to the benefit of any member of the College, nor will any assets or properties be used for the personal benefit of any member of any other person except in pursuit of the objectives stated in these Bylaws.
- Should the College dissolve, all assets and property remaining after meeting the obligations of the College will be donated to a substantially similar non-profit corporation or organization having objectives compatible with those of the College.

Leadership

The true success of an organization depends upon its leadership. Within the clinical engineering community there has existed a strong group of cutting edge people. Many were influential in the inception of ACCE, and through their selfless works ACCE has excelled. Some of these important volunteers took on the leadership roles on the board of directors or various committees. Table 130-3 lists the presidents of ACCE from its inception to 2003.

Table 130-3 Past Presidents of the American College of Clinical Engineering

1990–1991	Yadin David	1998–1999	Robert L. Morris
1991–1992	Matthew F. Baretich	1999–2001	Jennifer C. Ott
1992–1994	Joseph F. Dyro	2001–2002	Elliot Sloane
1994–1996	Thomas Bauld	2002–2003	Raymond Zambuto
1996–1998	Frank Painter	2003–2004	Izabella Gieras

Education

Among the major benefits of membership in the ACCE are the educational opportunities. They are directly related to the mission of the organization. Two general committees help with this task: The Education Committee and the International Committee. The committee chairpersons assist the board of directors and other ACCE committees in carrying out the educational mission of ACCE. They address requests from the constituency as well as support of clinical engineering educational activities throughout the world.

Teleconference Series

Annual meetings held by organizations are often highly beneficial to those who can afford the time away from work and the travel expenses. The Education Committee realized early on that an opportunity existed to provide an ongoing educational program in which attendees could participate in an hour-long teleconference. Thus, the annual ACCE Teleconference Series was born.

Each year, the Education Committee develops a list of eight to ten critical and timely topics and locates an expert who is willing to speak for 40–45 minute. This presentation is followed by a short question-and-answer session. ACCE members can join for a discounted rate that allows up to four participants per site. Additional persons may participate for \$10 each. Each site receives dialing instructions, handouts, a session evaluation, and a sign-in sheet. Depending upon the topic, some sites will invite other members of their organization, such as clinical staff who will appreciate the topic being covered, or they may invite other members of a local biomedical society. The speaker receives an honorarium from ACCE for their hard work. Previous topics are shown in Table 130-4 (see Chapter 72 for a complete discussion of the role of the ACCE Teleconference Series in distance education).

Advanced Clinical Engineering Workshops (ACEWs)

The Education Committee, in conjunction with the International Committee and sponsoring international organizations such as WHO and PAHO, will provide a three-day (or up to a two-week) educational conference specifically targeting the education of clinical engineering and health care technology management. The purpose is to provide an educational forum whereby clinical engineers and related health professionals in other countries can be introduced to the clinical engineering management systems and working methods practiced in the United States, and to exchange information and ideas pertinent to clinical engineering here. These advanced clinical engineering workshops (ACEWs) also provide opportunities for engineers in the host country to learn about ACCE and to become members (ACCE web site, International Page, 2002). To date, over 15 workshops have occurred throughout the world. The workshop faculty comprise volunteers from the ACCE membership, and interested members are encouraged to volunteer. A fee paid to ACCE covers the travel expenses for the faculty of the workshop. Locations of previous workshops include: Brazil, China, Costa Rica, Cuba, the Dominican Republic, Ecuador, Italy, Lithuania, Mexico, Nepal, Panama, Peru, Russia, South Africa, the United States, and Venezuela (see Chapters 70 and 71 for complete descriptions of the ACEW programs).

Infratech

Infratech was created in January 1999 by Dr. Andrei Issakov of the World Health Organization and Antonio Hernandez of the Pan American Health Organization as an Internet discussion group for exchange of information on health care infrastructure and technology for health services. Information gathered through this exchange can be used in developing a knowledge base for use in future projects (Jakniunas, 2000). This is an English-language listserv that provides a forum for international and national members to share clinical engineering information. There are an estimated 150 members from 50 countries, with a 20% ACCE membership. ACCE is the coordinator of this PAHO- and WHO-sponsored activity (International Committee Report, 2002). Future considerations include a calendar of worldwide health care technology management related events, a

Binseng Wang	Repair or Replace? The Hospital CFO's Point of View (Levenson, 2002)

listing of participants, a resource library, a message board, and utilization of participants to facilitate communications between the developer and users of the Essential Health Technology Package (EHTP) to share common experiences and to build common understanding (Jakninas, 2000; Judd, 2002; Nunziata, 2003).

Publications

ACCE has been involved with many publications through the organization itself and its members. The main ACCE publication, the *ACCE News*, will be discussed later. Other ACCE publications were done at the request of the board of directors to benefit the membership or the clinical engineering profession. Some examples include: *Guidelines for Medical Device Donations* and the *Patient Safety White Paper*.

Conferences

ACCE has always been involved with other organizations that help to foster the profession of clinical engineering, such as AAMI, ECRI, HealthTech, ASHE, and IEEE EMBS. ACCE has worked closely with these organizations to develop content and to provide speakers for various meetings and annual expositions, paying particular attention to topics that are of interest to the ACCE membership. The success of many of these conferences has been due to ACCE involvement. ACCE has run individual sessions and entire educational tracks. Occasionally, ACCE members will request ACCE sponsorship in the form of name support when presenting at conferences. The board of directors, under strong negotiations with other organizations, has provided ACCE member discounts to the conference and a forum for members to gather and discuss ACCE business. It is important for ACCE to continue these collaborative efforts to promote the profession and to provide further opportunities for the ACCE membership. Future projects might include providing speakers and material for other non-clinical engineering-based conferences, to introduce them to field clinical engineering and the role they play in the health care setting.

Certification

ACCE and the clinical engineering community at large gave the United States Board of Examiners for Clinical Engineering Certification a mandate to establish and maintain a credible certification program. The program, established in 2002, serves to provide meaningful certification for clinical engineering professionals. Prior to ACCE's involvement with the certification of clinical engineers, certification was administered by the Association for the Advancement of Medical Instrumentation. For various reasons, the AAMI program did not thrive, and AAMI discontinued its role in clinical engineering certification.

The ACCE program (described below) has provisions to recognize individuals who are certified under the previous system. Up-to-date information with regard to the mechanics of the certification program, e.g., applications, fees, examination dates and locations, those interested may visit the web site certification@ACCEnet.org or contact ACCE directly.

Governance

The governance structure of the program is now in place and is depicted in Figure 130-1. The relationships, bylaws, and constitution of the organizations in the governance structure were developed to comprehensively address the requirements of a valid and defensible certification program, fitting together in a cohesive manner. The required development work ensures the appropriate authority of each entity related to the certification program. In this structure, the following responsibilities exist:

- The foundation is responsible for the financial management of the commission and the board.
- The commission is responsible for establishing performance criteria for the certification program, communication between the board and the foundation, including about

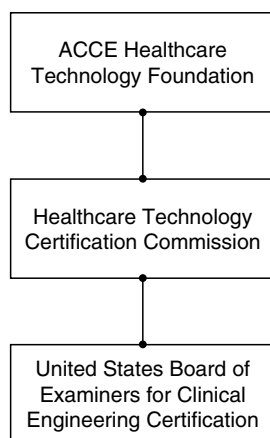

Figure 130-1 Governance structure of the Clinical Engineering Certification Program.

financial and budgetary matters, and is the authority by which all certifications will be issued.

- The board is responsible for developing and implementing all policies and operating procedures that are necessary to maintain the certification program in compliance with the standards set forth by the commission.

In accordance with its responsibilities, the commission has worked with the foundation and the board to project the financial needs to establish and maintain the certification program over its first few years. Although a large amount of volunteer labor is invested in the program, there are considerable expenses to bear, including insurance costs, administrative-support labor, document storage costs, and services that lie outside the realm of the expertise of the program participants. One of the required services to support a defensible examination process is psychometric analysis. This analysis confirms that the examination truly assesses the competence of the clinical engineers.

National Accreditation of Certifying Organizations Standards

The Commission has adopted standards for the certification program, based on those established by the National Organization for Competency Assurance (NOCA), which is a membership association of certification organizations that provide technical and educational information concerning certification practices. These standards address the following:

- Purpose, governance, and resources
- Responsibilities to stakeholders
- Assessment instruments
- Recertification
- Maintaining accreditation

The certification program can be evaluated directly by NOCA for compliance with these standards only after the certification examination has been given twice at a national level. The commission has directed the board to develop a program based on these standards.

Body of Knowledge

In accordance with its defined responsibilities, the board has been drafting policies, procedures, and practices that address all of the standards as well as the pertinent legal issues. This includes developing justifiable eligibility criteria and an application form with supporting documents. One of the important early board decisions was to adopt the body of knowledge as defined by the American College of Clinical Engineering as the current performance domain against which competence will be measured. According to the certification program standards, it will be necessary for ACCE to update that body of knowledge periodically in order for the board to continue to use it as the defined performance domain. Another important activity of the board is to develop questions around the body of knowledge using recognized references as the basis for the questions. Using this approach, the questions (and answers) are defensible. As the questions are written, they are catalogued in such a way as to facilitate updating them in the future while remaining true to the breadth of the body of knowledge. The board is currently evaluating test services to psychometrically analyze the questions and the examinations as well as to help establish a valid cut score. Finally, the board is establishing appeals processes for any candidate who does not agree with a decision of the board. While the examination-development process described above consumes much of the board's time, other issues are being addressed in parallel, including:

- Development and maintenance of a registry of certified clinical engineers
- Processes related to recertification
- Administrative processes for storage and retrieval of appropriate documents
- Development of an orientation and education program for board members

While all of this work is in progress, the foundation, the commission, and the board are all committed to providing information to clinical engineers and the public. Because of the newness of the clinical engineering certification program, these entities are also sensitive to the need maintain credibility and hence they strive to release information only when the interactive development of specific pieces of the program is nearing completion. The foundation, commission, and board appreciate the patience of the ACCE members and their colleagues and looks forwards to disclosing the details about the certification program in the near future.

Validity and Value

Time spent reading about certification on the Internet reveals that the value of certification is debated in many diverse fields, including martial arts, human resources, and information technology. Within health care, the debate about the value of clinical engineering certification is several years old. In all industries, the debate must be separated into two issues: The validity of a certification program and the value of certification to others i.e., the public, the employer, and the individual. Certification can have value only if it is valid. If a certification is valid, market forces drive the value of the certification.

In the absence of an active, viable program, clinical engineering certification has been devalued. In order to restore the potential for value, an active, valid clinical engineering certification program must be restored. The validity of the certification program depends on the ability of the program to authenticate that an individual can perform a specific set of tasks at an established level. That validity is largely dependent on the program's

ability to define the specific skill set of interest and to use an assessment instrument that truly assesses that skill set in a consistent and nondiscriminatory manner. Following standards such as those established by the NOCA helps to ensure the validity of a certification program.

Once a valid certification program is established, the market will determine the value of clinical engineering certification. Because of technology convergence, perhaps a glimpse at the value of certification in information technology is pertinent to the clinical engineering certification discussion. The Computing Industry Technology Association has provided the results of its 2001 Global Training and Certification Study at www.comptia.org/cla.

The results of that study demonstrate that 83% of IT professionals found certification to be helpful in acquiring a new position, while 66% of certified IT professionals reported that their salaries increased after becoming certified. Against the background of a maligned health care industry and a declining economy, these results suggest that employers will increasingly value certification, thereby causing one's professional viability and marketability to be strengthened through certification. This value is only possible if a valid program exists.

The United States Board of Examiners for Clinical Engineering Certification (USBE-CEC) continues its efforts to develop a valid certification program. While this development process is laborious and time-consuming, the program will add value by promoting health care delivery improvement in the United States through the certification and continuing assessment of the competency of professionals who support and advance patient care by applying engineering and management skills to health care technology. In turn, the patience of the clinical engineering audience will be rewarded with increased value to clinical engineering certification.

Meetings

Symposia

In 1998, ACCE held its first of five annual symposia. These are day-long educational endeavors for the ACCE membership, held in conjunction with the annual AAMI meeting and exposition dedicated, to hot topics and to providing critical in-depth information. The first symposium was titled *The Future of Clinical Engineering* and included panelists Malcolm Ridgway, Larry Hertzler, Tom Bauld, Greg Davis, and moderator Ira Tackel. Together, they provided informative talks and sparked lively discussion on where clinical engineering is headed (Dyro, 1998).

The second symposium was titled *The Future of Clinical Engineering—Clinical Engineering and Information Systems* and included moderator Brian Porras and panelists Tom Bauld, Dean Athanassiades, and Richard Schrenker, who discussed the future relationships between clinical engineering and hospital-information systems and methods to develop partnerships (Porras, 1999).

The third symposium was titled *Frequency Allocation Issues in Medical Telemetry* and included a panel of experts from government, the medical device industry, and the hospital community, such as moderator Brian Porras, Caroline Campbell, Steven Juett, David Paperman, Don Witters, Mary Beth Savary Taylor, Stan Wiley, and David Pettijohn. There was extensive discussion of the new regulatory changes to extend protections to electromagnetic frequencies used by medical telemetry (Porras, 2000).

The fourth symposium was titled *The Health Insurance Portability and Accountability Act (HIPAA)*. Its goal was to educate ACCE members on the HIPAA federal regulations that will require health care providers to protect the privacy and security of individually identifiable health care information. The final rules will affect virtually all high technology in health care and will impact many departments. Moderators Steve Grimes and Ray Zambuto lead panelists Madelyn Quattrone, M. Peter Adler, Ely Lezzer, Alan S. Goldberg, Charles Parisot, and Tom Walsh.

The fifth symposium was titled *Perspective for Successful Leadership in Clinical and Information Technology Services*. Fourteen speakers presented an outstanding program focusing on the information technology and clinical engineering perspective and included case studies (Cohen, 2002).

General Membership Meetings

According to the ACCE bylaws, at least one annual membership meeting is held in April, May, or June. Generally, it is held in conjunction with another society annual meeting, usually AAMI. There might be additional general membership meetings at other conferences held throughout the year if there will be an ACCE contingency attending. Meeting announcements are sent to members and are posted on the web site and in the *ACCE News*. The annual membership meeting begins with a social hour that includes a wine and cheese reception and then a summary of ACCE activities from the previous year is presented to the membership. In addition, the Advocacy Award winners are announced and celebrated, as are outgoing board members. The meeting concludes with a presentation of the slate of officers for the upcoming year and an open forum to address membership issues, questions, and concerns.

Board Meetings

The board of directors meets at least quarterly and usually bimonthly. They are conducted via conference, call with items being distributed by e-mail. On an annual basis, there is one live meeting prior to the annual membership meeting. The executive board meets monthly via conference call. (Please see the bylaws for other specific meeting guidelines.)

Committee Meetings

Committee chairmen organize and develop their own meeting schedules to address the tasks at hand. The bylaws provide some guidance on deadlines for standing committees,

such as Membership and Nominations. Most committees use teleconferencing and e-mail as the primary methods of communication among committee members.

Cooperating Organization Meetings

ACCE works very closely with other organizations in developing educational materials and content for their meetings as well as honoring requests to participate in their organization-driven projects. Some of these co-operating organizations include: ASHE, AAMI, HealthTech, ECRI, the American Institute of Medical and Biological Engineering (AIMBE), IEEE, World Health Organization (WHO), Pan American Health Organization (PAHO), and the International Federation for Medical and Biological Engineering (IFMBE) Clinical Engineering Division (CED).

Advocacy Committee

The Advocacy Committee has one of the most important roles within ACCE and is integral to the mission of ACCE. Clinical engineering is a relatively small, but important, profession that is often misunderstood. A group of forward-thinking clinical engineers understood these limitations and formed ACCE. The Advocacy Committee recognizes those members who have fulfilled the ACCE mission, and it provides opportunities for ACCE members to further develop the profession by educating younger generations and colleagues on the field of clinical engineering and its importance to the health care team.

Advocacy Awards

The Advocacy Committee administers the Advocacy Awards program. Through this program, clinical engineering excellence and advocacy are recognized. If the nominee is a clinical engineer, he or she must be a member in good standing with ACCE. The categories of awards are described below.

Professional Achievement

The Tom O'Dea Professional Achievement Award recognizes work in defining the exclusive limits for the practice of clinical engineering; i.e., identifying unique functions, roles, activities, duties, and responsibilities of clinical engineers. The work should be either published in a journal of professional standing or at a conference of a professionally recognized, health-related organization. Publications and presentations must incorporate the words "clinical engineer" or "clinical engineering" in their titles. Terms used must be consistent with the ACCE definition of "clinical engineer" (Johnston, 1995). Past winners of the Professional Achievement Award are listed in Table 130-5. In 2002, the name of this award was changed to the Tom O'Dea Professional Achievement Award in recognition of all of Tom O'Dea's great work and contributions to the clinical engineering profession (Gieras, 2002).

Professional Development

The Professional Development Award recognizes accomplishments of professional advocacy which promote awareness and appreciation of clinical engineering within other health care professions. These actions are mainly through publications and presentations in a distinctly non-engineering health related publication or conference. Publications and presentations must incorporate the words "clinical engineer" or "clinical engineering" in their titles. Terms used must be consistent with the ACCE definition of "clinical engineer" (Johnston, 1995). Past recipients of this award and the title of their papers are listed in Table 130-6.

Managerial Excellence Award

Begun in 1999, the Managerial Excellence Award has been granted to those who have published articles promoting clinical engineering in the field of management development (see Table 130-7).

Table 130-5 Recipients of the Professional Achievement Award

<i>Professional Achievement Winners</i>		
<i>Year</i>	<i>Author</i>	<i>Title</i>
1995	Wayne Morse	Career Opportunities in Clinical Engineering
1995	Monique Frize and Michael Shaffer	Clinical Engineering in Today's Hospital: Perspectives of the Administrator and the Clinical Engineer (Johnston, 1995)
1996	Lucio Flavio Brito	Seguranca No Ambiente Hospitalar (Johnston, 1996)
1997	Tom O'Dea	Protecting the Immunocompromised Patient (Johnston, 1997)
1998	Marvin Shepherd	Investigating Equipment-Related Incidents and an SMDA Update Risk Managers and Clinical Engineers Working as a Team (O'Dea, 1998)
2000	Manny Furst	Sixteen Years as Chairman of the AAMI's Clinical Engineering Management and Productivity Committee (Campbell, 2000)
2001	Eric Rosow and Joseph Adam	Virtual Instrumentation Tools for Real Time Performance Indicators. (Campbell, 2001)
2002	Tom O'Dea	For his committee leadership and the article he wrote in response to the confusing ad for a clinical engineer, in which it was clear the employer did not know what a clinical engineer was.

Table 130-6 Past recipients of the Professional Development Award

<i>Professional Development Winners</i>		
<i>Year</i>	<i>Author</i>	<i>Title</i>
1995	Enrico Nunziata and Awa Diouf	Gestation Des Infrastructures et Des Equipment's Sanitaires (Johnston, 1995)
1996	Lucio Flavio Brito	Exposafide '95 and Guia de Fornecedores Hospitalares (Johnston, 1996)
1997	Ira Tackel	Non-Traditional Support: Patient TV System and Biomedical Equipment Service—An International Incentive? (Johnston, 1997)
1998	Michael J. Shaffer	Clinical Engineers: A Vanishing Hospital Resource (O'Dea, 1998)
1999	Ira Soller	Contribution to the <i>Encyclopedia of Electrical and Electronics</i> edited by John Webster and published by Wiley (O'Dea, 1999)
2002	Joseph D. Bronzino	For his development of the Graduate Program in Clinical Engineering and his work with BEACON plus the numerous articles and books throughout his career (Gieras, 2002)

Table 130-7 Recipients of the Managerial Excellence Award

<i>Managerial Excellence Award Winners</i>		
<i>Year</i>	<i>Author</i>	<i>Title</i>
1999	Binseng Wang	Letter to Consumer Reports taking to task certain Y2K issues raised concerning the compatibility of ECG Devices. (O'Dea, 1999)
1999	Dave Dickey and Larry Hertzler	Cover Your Assets. (O'Dea, 1999)
2001	Binseng Wang and Al Levenson	Equipment Inclusion Criteria—A New Interpretation of JCAHO's Medical Equipment Standard. (Campbell, 2001)
2002	Ted Cohen	For his several articles written over the years on Maintenance Management Systems and other related topics. (Gieras, 2002)

Devteq

In 1999, the Devteq Award was created, thanks to the support and encouragement of Marvin Shepherd, who wanted to reward those clinical engineering professionals who contributed to the rational balance between safety and resource management. Past winners of this award are listed in Table 130-8.

Devteq Challenge Award

In conjunction with the stipulation of the Devteq Award, ACCE Board of Directors awards at least one complimentary membership to a clinical engineering professional who is not currently a member, in hopes of enticing them to start and then continue their membership in future years. Past recipients of this award are shown in Table 130-9.

Guidelines and Recommendations

The Advocacy Committee has always taken on the role of monitoring clinical engineering activities in government and publications. Occasionally, a member will be asked to

Table 130-8 Recipients of the Devteq Award

<i>Devteq Award Winners</i>		
<i>Year</i>	<i>Author</i>	<i>Title</i>
1999	Dave Francoeur	Impact upon the College of American Pathologists (CAP) to change their lab equipment electrical safety testing requirements from arbitrary annual inspection to (1) incoming inspection; (2) after major repair; (3) at a risk-based criteria frequency consistent with the equipment-management program of the institution (O'Dea, 1999).
2000	Steve Juett	Recognition of his identification of DTV interference at the Baylor University Medical Center in February 1998, his interaction with the press concerning that event, and his participation on the AHA Telemetry Task Force (Campbell, 2000)
2001	Jeffrey Cooper	His work in anesthesia safety in particular his response to the report on medical errors, which has significantly advanced the cause of patient safety (Campbell, 2001)
2002	Leslie A. Geddes	For his numerous patient-safety efforts through research, education, and publications (Gieras, 2002)

2001	Jeffrey Cooper
2002	Leonard Klebanov and John Czup

draft a response to an article, editorial, or position advertisement in order to clarify ACCE's position and to further educate the community at large on ACCE and its activities. Letters to the FDA have been written by the ACCE president, and other lobbying efforts occur as needed and as allowed under our current organizational structure.

Publicity

ACCE has developed educational and publicity material to assist members in the efforts to promote the profession and has set up booths at meetings. The first brochure developed, *The American College of Clinical Engineering*, was on ACCE itself and provides an introduction, mission statement, definitions, membership information, and contact information. The second brochure was titled *What's a Clinical Engineer?* It provides information for clinical engineers to educate others who did not know or understand the profession. A third brochure, entitled *American College of Clinical Engineering Providing Clinical Engineering Support to Countries Worldwide*, describes the International Committee and the role of ACCE as a coordinating body for improvement of clinical engineering skills and for exchange of technical information with colleagues around the world. The generous assistance of ECRI made possible the publication of these brochures.

Health Care Technology Foundation

Formation

ACCE, at the request of the board of Directors, established the ACCE Healthcare Technology Foundation, an independent foundation to assist in the oversight of the certification process and other advocacy efforts. In August of 2001, the ACCE board of directors passed a motion to create an exploratory task force to investigate the establishment of a not-for-profit foundation. When ACCE was founded, it was known that in order to enable the organization to reach further professional goals and to continue to build the legacy on which the field of practice is based, the creation of a not-for-profit foundation (and its associated fundraising) potential was needed.

When the collective wisdom of senior members of ACCE, the exploratory task force, was put to the test, a report to the board resulted, showing that a foundation will significantly enhance the ACCE mission and that it should be created as soon as possible. Additional support for this recommendation was provided by the AAMI decision to discontinue its support of the clinical engineering certification process. With ACCE as the only organization that supports and recognizes the important role of clinical engineering in the safe and efficient development, integration, and use of modern health care technologies, a closely related foundation was considered to be like an oasis in the middle of a desert.

In May 2002, the ACCE board gave its approval for the creation of a foundation and provided the necessary seed money needed for filing and registering the foundation at the state and federal levels. A slate of directors and officers were selected, and work began on the foundation mission, objectives, and by-laws. This moment could not have been reached had it not been for the dedication of individuals like Matthew F. Baretich, Thoms J. Bauld, Yadin David, Joseph F. Dyro, Wayne Morse, Jennifer C. Ott, Frank Painter, Marvin Shepherd, Elliot B. Sloane, Ira Tackel, and Ray Zambuto. Assistance provided by Joe Welsh made this dream a reality. The effect of the work of these dedicated individuals probably will not be felt immediately, but future generations of clinical engineers and other practicing professionals in health care delivery system stand to benefit greatly. Some are known as doers, others as professionals, and yet others are dreamers. This above group comprised each of these. The first order of business was to organize a way to jump-start and sustain the certification process.

At the end of 2002, the ACCE Healthcare Technology Foundation was inaugurated and registered in the Commonwealth of Pennsylvania and proceeded to file with the federal authorities under Section 501(c)(3) of the tax code as a not-for-profit foundation. The foundation's purpose is as follows:

Improving of Health Care Delivery by Promoting the Development and Application of Safe and Effective Health Care Technologies Through the Global Advancement of Clinical Engineering Research, Education, Practice, and Other Related Activities.

Officers are Yadin David, president; Ira Tackel, treasurer; and Jennifer Ott, secretary. Other board members include Matt Baretich, Tom Bauld, Joe Dyro, Wayne Morse, Frank Painter, Elliot Sloane, Marvin Shepherd, Joe Welsh, and Ray Zambuto.

Robert M. Morris Humanitarian Award

In 2001, Elliot B. Sloane, in conjunction with other ACCE members and the ACCE board of directors, pursued through the AAMI foundation the development of an award to recognize a longtime ACCE leader, Robert L. Morris. During the next 12 months, funding was secured through the Manual and Beatrice Sloane Foundation and numerous contributions from ACCE members and others who have worked with Bob Morris through the years. The hope was to present the first award to Bob, but unfortunately he passed away in March 2001. He was granted the award posthumously. Table 130-10 lists award recipients and the reasons for their recognition.

Table 130-10 Robert M. Morris Humanitarian Award

Year	Recipient	Recognition
2001	Robert L. Morris	Bob Morris was posthumously honored as the first recipient of the annual humanitarian award that now bears his name at the AAMI Awards Luncheon in June of 2001 in Baltimore, Maryland. Ms. Julie Morris, Bob and Colleen Morris's younger daughter, received a check for \$1,000 and the inaugural plaque with Bob's name on it. Julie expressed her family's appreciation for honoring her father by creating this award in his name and for recognizing Bob's humanitarian efforts and his passion for clinical engineering (Sloane, 2002)
2002	Herman R. Weed	A retired professor of electrical engineering and preventive medicine from Ohio State University; for over 30 years he has been involved with many humanitarian activities, a majority of them sponsored by Project Hope, a nonprofit foundation. Professor Weed served as director of Project Hope's Biomedical Engineering Programs. He was responsible for designing, supervising, and monitoring clinical engineering assignments of all sizes and scopes. In this role, he served as an inspiration to Bob and many other clinical engineers who participated in these projects throughout the world (Ott, 2002)

Newsletter

ACCE News is the official newsletter of ACCE. The *News* is published bimonthly and keeps the membership current with regard to important developments in the organization (e.g., election of officers), significant board decisions (e.g., establishment of Healthcare Technology Foundation), ACCE programs (e.g., Annual Symposium and Audio-Teleconference Series), and events in the clinical engineering world (e.g., National Patient Safety Movement, HIPAA, Telemetry Standards, and FDA Proposed Rules). The *News* has benefited from the editorial skills of four members who, as volunteers, solicited material; threatened, wheedled, and cajoled members to put their wisdom on the printed page; organized the material into an attractive format; and edited the final product. ACCE stands in deep appreciation of the efforts of Editors David Harrington (1990–1993), David Simmons (1993–1994), Mark Brody (1995–1996), and Joseph F. Dyro (1995–2003).

Content

Regular columns include the "President's Message," "Certification Update," "HIPAA Update," "Perspectives from ECRI," "The View from the Penalty Box," "Highlights of Board Meetings," "Calendar of Events," "People on the Move," "In the News," and "Advertisements." In addition to the regular columns, as news comes in, the following items are published in the *News*: "CE around the Globe," "Clinical Engineering Department Profiles," "ACCE Teleconference Series Announcements," "Reports of Meetings," "Reports of Advanced Clinical Engineering Workshops," "Conferences and Symposia," "Guest Editorials," and "Member Survey Results."

Highlights

Since its inception in 1990, much has been written in the *News*. Some of the highlights are mentioned here. A special issue of *ACCE News* chronicled the life and times of Robert M. Morris (Vol. 11, No. 2–March 2001). Below, the authors list articles that they find to be particularly interesting and insightful.

- Dyro JF. Advanced Clinical Engineering Workshop in Russia. *ACCE News* 9(5–6):12–17, 1999.
- Harrington D. The View from the Penalty Box. *ACCE News* 10(1):9, 2000.
- Judd T. EHTP in Kyrgyzstan. *ACCE News* 12(2):20–23, 2000.

The New England Society of Clinical Engineering

Nicholas T. Noyes

Director, Department of Clinical Engineering
University of Connecticut Health Center
Farmington, CT

The New England Society of Clinical Engineering (NESCE) is an example of a local organization for clinical engineers, biomedical electronics technicians, and medical product sales and service representatives. NESCE organizes educational opportunities, such as guests, lecturers, and site visits to medical device manufacturing facilities, and conducts regular meetings in a social setting. Every several years NESCE is one of several New England clinical engineering and BMET societies that host the Northeast Biomedical Engineering Symposium.

Goals

As stated in the bylaws of the New England Society of Clinical Engineering, the goals of the Society are as follows:

- To promote better patient care through improved maintenance, operation, and application of medical instrumentation
- To promote the mutual exchange of information and technical assistance among clinical engineers (CEs) and biomedical electronics technicians (BMETs)
- To promote the development of the clinical engineering profession
- To organize and promote an educational program for CEs and BMETs
- To disseminate uniform interpretations of codes and standards pertaining to clinical engineering.

These goals were developed in the formative years of the Society and have remained to the present.

History

As reported by Mark English (Hartford Hospital), the New England Society of Clinical Engineering was launched on December 10, 1975. Several clinical engineering managers representing Connecticut and western Massachusetts hospitals held an informal meeting at Manchester Memorial Hospital. Among others, the original members included Allan Hoffman (Manchester Hospital), Norm Bertera (Baystate Medical Center), David Reese (Middlesex Memorial Hospital), Thomas Hayes (St. Francis Hospital and Medical Center), Robert Piscane (Providence Hospital, Holyoke, MA), Mark English (Hartford Hospital), Dr. Ernie Guignon (U. of CT Health Center), and John Gilbert (New Britain Hospital). These first meetings were hosted by local hospitals on a monthly basis, typically with lunch provided. During these early years, the thrust of the meetings was to share problems and ideas and network at the management level.

The 1980s brought growth to the Society, with the membership roster expanding to over 200, including CEs, BMETs, service personnel from medical device manufacturers, medical-product sales representatives, and independent biomedical equipment service professionals. Formal bylaws for the New England Society of Clinical Engineering were established on November 20, 1987. Many would agree that the 1980s were golden years for the profession. In-house clinical engineering departments were valued and supported with sufficient resources and personnel to allow time, energy, and finances for clinical engineering extracurricular activities.

In addition to the original Society members listed above, some of the key personnel serving as officers and leaders of NESCE during the 1980s were as follows:

Frank Painter (Bridgeport Hospital), Nicholas Noyes, Anton Hebenstreit and Anna Marie Mercurio (U. of CT Health Center), Roger Debaise (Gaylord Hospital), Raymond Acosta and Tony Acavalla (Yale New Haven Hospital), Michael Romeo (Manchester Memorial Hospital), Dr. Joseph Bronzino (Trinity College), Robert Capetta (New Britain General), Robert Zbuska (St. Francis Hospital and Medical Center), Joseph Cane (St. Mary's Hospital), Mark Brody and Joanne Belden (Baystate Medical Center), Merrill Allen (Biotek, Inc.), and Martin Shapiro (Norwalk Hospital).

During the 1990s, NESCE's focus shifted to reflect the increasing financial pressures on health care institutions. As hospital directors changed their titles to "chief executive officers" and administrators became "vice presidents," the in-house clinical engineering programs were challenged to justify their role in supporting the hospital's bottom line. In response to these challenges, the Society's topics of interest became finance, benchmarking, and productivity. Asset management, equipment maintenance management, and maintenance insurance became the buzzwords of the profession and presented new vehicles for financing the hospital's medical technology programs. Society members were challenged to re-examine their niche in the health care landscape.

As a consequence, in the new millennium, several clinical engineering departments have been aligned with information technology services departments and also have assumed responsibility for telecommunications, nurse call systems, and patient television services. Traditional service areas are changing and with it, NESCE educational programs have been broadened to include such topics as "Networking, Hubs, Switches, and Servers" and "Wireless Networking Architectures."

To encourage the exchange of information and to open new lines of communication among the members, NESCE initiated its own web site, www.nesce.org with newsletters, meeting announcements, job listings, and other postings and links. Frank Painter (Technology Management Solutions, LLC) created and licensed the web site in the summer of 1999 and has been expanding it ever since. Our primary method of communication for the Society is now via the Web and e-mail distributions.

Past officers and active members since the 1990s include the following:

Anthony Guilietti and David Dittrich (Hospital of St. Raphael), Henry Montenegro (Waterbury Hospital), Shelley Steffy (Lawrence Memorial Hospital), Dave Crawford and Dave Reihl (Novamed Biomedical Technology Services), John Elwood, Rebecca Thomson, and Vinnie DeFrancesco (Hartford Hospital), David Wilder and Robert Payne (Yale New Haven Hospital), Tom Chenail (Technology in Medicine), Dave Francoeur (Fischer Consulting), and Carolyn Mahoney (VA Medical Center).

Affiliation

Since the early 1980s, NESCE has been associated informally with three other northeastern clinical engineering societies: The Medical Device Society (MDS) in greater Boston, the Iroquois Biomedical Society (IBS) in the Albany area, and the Northern New England Society of Biomedical Equipment Technology (NNSBET), which encompasses Vermont, New Hampshire, and Maine. These alliances have been maintained over a period of 20 years. Each year, the four societies cosponsor the Northeastern Biomedical Symposium. The responsibility for planning and hosting the Symposium rotates among the four societies each year (Dyro, 1997). The hosting society manages the finances, hotel, vendor, and program development, while the other three provide mutual aid in the form of shared membership lists, presentations, friendly competition, and attendance.

The first Symposium was held in Danvers, MA, in 1981. The 20th was held in Sturbridge, MA, in 2001. NESCE hosted Symposia #1, 2, 5, 9, 13, 17 (Dyro, 1997), and 20 (Francoeur, 2002). The most recent Symposium, which was highlighted by 350 in attendance, 52 vendors, two keynote speakers, and the standard Certified Biomedical Electronics Technician (CBET) Review course and certification examination. The infamous Biobowl (a *Jeopardy*-like contest among the Societies, vendors and students) was replaced by a hayride and fireside dinner roast—a possible sign of a mellowing among members, who value fine food over academic and troubleshooting prowess. The author holds the distinction of initiating the Biobowl Competition at the 9th Symposium in 1989, borrowing the concept from the Respiratory Therapist's Sputum Bowl, which was patterned after the College Bowl format.

Since 2000, the Northeastern Biomedical Symposium alliance has suffered in that IBS and MDS are no longer active. The format and frequency of the Northeastern Biomedical Symposium undoubtedly will change in future years.

NEW ENGLAND SOCIETY OF CLINICAL ENGINEERING BYLAWS

ARTICLE I.

Name

The name of this Society shall be the New England Society of Clinical Engineering.

ARTICLE II

Objectives

The objectives of this Society shall be:

- To promote better patient care through improved maintenance, operation, and application of medical instrumentation;
- To promote the mutual exchange of information and technical assistance among Clinical Engineers and BMETs;
- To promote the development of the Clinical Engineering profession;
- To organize and promote an educational program for Clinical Engineers and BMETs; and
- To disseminate uniform interpretations of codes and standards pertaining to Clinical Engineering.

ARTICLE III

Membership

Section 1. This Society shall have three types of membership: Full member, associate member, and student member.

Full members shall be persons activity involved in the practice of Clinical Engineering who are employed by a health care institution.

Associate members shall be persons with an interest in Clinical Engineering.

Student members shall be full-time students with an interest in Clinical Engineering. Associate and student members will have all of the privileges and rights of full members except holding office. Membership in the Society shall become effective upon approval by the Executive Committee of a completed application form and upon receipt of specified dues.

Section 2. The annual dues for all classes of membership shall be as set by the Executive Committee and approved by the membership. Dues shall be payable prior to or at the first meeting of the calendar year. All members must pay their dues in order to retain voting and attendance privileges.

ARTICLE IV

Officers

Section 1. The officers of this Society shall be a President, Vice President, Secretary, and Treasurer. These officers shall perform the duties prescribed by these bylaws.

Section 2. A Nominating Committee composed of at least two (2) full members shall be appointed by the Executive Committee sixty (60) days prior to the elections in April. It shall be the duty of this Committee to nominate candidates to the offices to be filled. The state of nominees selected shall be made know at the March meeting, at which time additional nominations from the floor can be made. Only full members can be nominated. All nominees will be required to submit a brief statement to the Secretary outlining their reasons for seeking office along with a description of their experience and qualifications. No member of the Executive Committee can be a member of the Nominating Committee.

Section 3. A Teller Committee composed of at least two (2) full members shall be appointed by the Executive Committee after the close of nominations. Members currently holding office (except the President) or candidates for office are not eligible for membership on this Committee. The Teller Committee is responsible for receiving and tabulating all ballots during the election. This Committee shall elect a Chairman from amongst its membership.

Section 4. Ballots will be mailed to all members listing all candidates prior to April 1. The ballot will include a brief statement describing each candidate's affiliation, reasons for seeking office, experience and qualifications. Returned ballots shall be sent to the Chairman of the Teller Committee so that they are received prior to or on the last day of April. Officers will be elected by simple majority. Election results will be announced at the next business meeting by the Chairman of the Teller Committee.

Section 5. Elections will be held every year for the position of Vice President.

The Vice President automatically becomes President at the end of his/her term of office. Elections will be held every even-numbered year for the position of Secretary and every odd-numbered year for the position of Treasurer.

Section 6. Term of Office shall begin at the first business meeting following the end of the elections and shall run until the meeting following the next election.

No member shall hold more than one office concurrently and no member shall be eligible to serve more than two (2) consecutive terms in the same office.

ARTICLE V

Executive Committee

Section 1. Officers, the immediate past President and Standing Committee Chairmen shall constitute the Executive Committee.

Section 2. The Executive Committee shall have general supervision of the affairs of the Society between its business meetings, fix the hour and place of meetings, make recommendations to the Society and shall perform such other duties as specified in these bylaws.

The Executive Committee shall appoint a full or associate member, other than the Treasurer, to perform an audit of the Society's financial records to be completed by the annual meeting.

The Executive Committee shall be subject to the orders of the Society, and none of its acts shall conflict with action taken by the Society.

ARTICLE VI

Committees

Section 1. There shall be such standing and ad hoc committees as are needed, to be established and appointed by the Executive Committee.

Section 2. The appointment and composition of the Nominating and Teller Committees will be as designated in Article IV, Sections 2 and 3.

ARTICLE VII

Parliamentary Authority

Roberts Rules of Order Newly Revised shall govern the meetings and business of the Society in all cases to which they are applicable which are not specifically covered by these bylaws or any special rules the Society may adopt.

ARTICLE VIII

Meetings

Section 1. Meetings of the Society shall be held at a time and place determined by the Executive Committee. One meeting (preferably the May meeting) shall be designated the Annual Meeting.

Section 2. Special meetings can be called by the President, Executive Committee or upon written petition by ten (10) members. At least ten (10) days notice shall be given and the purpose of the meeting stated in the meeting notice.

Section 3. Ten (10) full members of the Society shall constitute a quorum.

ARTICLE IX

Amendment of the Bylaws

Section 1. A motion to amend the by laws can be made at any business meeting and must be seconded.

Section 2. If at least two-thirds (2/3) of the total eligible voting membership is present, the amendment may be voted upon. Two-thirds (2/3) of the total eligible membership must vote in favor of the amendment for passage.

Section 3. If the conditions stated in Article IX, Section 2 are not present, the Secretary shall mail a notice and ballot to all eligible members detailing the proposed amendment.

Section 4. Said ballots are to be returned to the Secretary within thirty (30) days from the mailing date. A two-thirds (2/3) majority of the total eligible membership must vote in favor of the amendment for passage.

Structure

Executive Committee

The NESCE Bylaws provide the structure of the Society. An executive committee supervises the affairs of the Society and comprises the officers and past president. The term of each officer extends for two years, and each year the vice president automatically succeeds to the presidency. A new vice president is elected, and on alternating years a new secretary or treasurer is elected. This arrangement provides a training period for new officers and ensures continuity in NESCE leadership.

Officers

The duties of the officers are also defined in the Bylaws. The president presides over all general meetings and executive committee meetings, often providing the driving force in NESCE activities. The vice president serves as program chair and arranges the logistics of the general meetings, including meal arrangements, reservations, and coordinating an

educational presentation for the membership. The secretary records minutes of the executive committee meetings; prepares and distributes mailings, announcements, and the *NESCE Newsletter*; and generally maintains communications with the membership. The treasurer bills and receives annual dues, maintains a checking account for NESCE, and reports to the membership on the Society's finances.

Meetings

The schedule, location, and program of the general meetings are determined by the executive committee and vary each year, although the meetings typically occur every other month between September and June. A dinner-meeting format has predominated through the years, meeting at restaurants in the urban centers of Connecticut as well as Springfield, Massachusetts, during mid-week evenings. The meeting format is as follows:

- 5:00 pm Cocktails
- 6:00 pm Dinner

7:00 pm Business meeting
 7:30 pm Educational program
 9:00 pm Adjourn

DUTIES OF THE OFFICERS

- A. Duties of the President**
1. Preside over all meetings of the Society.
 2. Preside over at meetings of the Executive Committee.
 3. Shall serve as an ex-officio member of all committees (except the Nominating Committee).
 4. Prepares an Annual Report outlining the current status and activities of the Society for the year for presentation at the Annual Meeting.
 5. Shall maintain a liaison with other regional Clinical Engineering societies.
- B. Duties of the Vice President**
1. Perform the duties and have the powers of the President in the absence of the President.
 2. With the approval of the Executive Committee, the Vice President shall assume the duties of any other officer unable to perform his/her duties.
 3. Serves as Program Committee Chairman, responsible for producing the educational programs held in conjunction with the monthly business meetings.
- C. Duties of the Secretary**
1. Records minutes of Executive Committee meetings and also general membership meetings.
 2. Prepares and mails announcements for general membership meetings at least two (2) weeks before each meeting, including program information, time, place, form of acknowledgment, and minutes of previous meetings, both general meeting and Executive Committee meeting.
 3. Updates membership lists and forwards a copy to each member periodically.
 4. Maintains correspondence file.
 5. Maintains supply of New England Society of Clinical Engineering supplies, e.g., stationery, except bill heads.
 6. Submits bills to Treasurer for payment, e.g., printing, posting, and stationery.
 7. Maintains a close liaison with Committee Chairmen and other members of the Executive Committee.
 8. Arranges for printing and distribution of membership certificates.
 9. Notifies general membership in writing, in advance of the election meeting, the slate of nominees.
- D. Duties of the Treasurer**
1. Bills and receives dues.
 2. Deposits moneys and pays accounts.
 3. Maintains on file, bank statements and records distribution of moneys.
 4. Maintains an accurate financial statement in readiness for report at every business meeting.
 5. Requires authorization of Executive Committee before incurring any indebtedness for the organization.
 6. Prepares a statement of accounting for the fiscal year for presentation to the membership at the final meeting.
 7. Informs Secretary promptly in writing of paid members.

Executive committees have tried different approaches to meeting locations, to enhance attendance. Some years, the location was varied widely to reflect the geographic make-up of the membership. Other years, the same restaurant in the center of Connecticut was used for each meeting. NESCE members will forever remember the prime rib dinners at Angelico's in New Britain. With respect to general meeting locations, no consistent formula seemed to guarantee high attendance. The dinner expenses are subsidized by the Society each meeting, which limits the typical membership contribution to \$15. Some years, new-member drives have been held in which anyone who brings a new member pays \$5 for dinner. The usual attendance has been 20–40, with this number almost doubling on these special membership drives. Another enticement at each meeting is a drawing, with the winner receiving \$25 to cover the cost of their travel and dinner.

The cocktail hour and dinner provide time for informal networking. During the business meeting, officer reports are presented; experiences with JCAHO, State Department of Health, and OSHA surveys are shared; job openings announced; and potential new hires are introduced to the membership.

As part of the general meetings, the educational program content has focused on current topics that are germane to the times and the profession, as well as programs expanding life skills. The technical programs are typically offered by manufacturers on new concepts in health care technology, or a review of the clinical aspects of medical instrumentation taught by a therapist, nurse, or physician. These topics have ranged from "Clinical Aspects of Mechanical Ventilation" to "Point-of-Care Laboratory Medicine" to "Medical Telemetry and Wireless Networks." The life skills programs have included "Time Management," "Dealing with Change," and "Humor in Medicine."

Occasionally, joint meetings have been held with the Connecticut Hospital Engineering Society, pooling our resources to sponsor a nationally known speaker on the JCAHO Environment of Care or environmental health and safety issues such as "Ethylene Oxide Use" or "Anesthetic Waste Gas Management." These meetings are exceptionally well attended and foster good interchange with the hospital engineering community. By extending the hand of friendship to a group of hospital engineers, a clinical engineering society can enlightening them to the group's perspectives of the important aspects of health care technology.

Membership

There are three types of memberships in NESCE: Full member, associate member, and student member. Full members are individuals who are actively involved in the field of clinical or biomedical engineering and are working in the health care technology arena. Associate members are individuals who have an interest in clinical and biomedical engineering and would include medical product sales representatives. Student members are full-time students who have an interest in the profession. Associate and student members have all privileges and rights of full members, other than holding office.

In 2002, NESCE membership stood at 352, which included all registrants from the last Symposium. The members who are actually located in Connecticut, Western Massachusetts, and Rhode Island total approximately 250 and are generally considered the active participants

Finances

There are no paid Officers in NESCE; all serve as volunteers. However, there are expenses associated with operating the Society. These include mailings, web site fees, subsidizing meetings, and sponsoring training programs. The finances to operate the Society come from annual membership dues and the shared revenues from the Northeastern Biomedical Symposia.

Annual membership dues have held constant at the following amounts:

- \$15: Full membership
- \$5: Student membership
- \$100: Corporate membership for up to 10 members from the same facility.

Many hospitals exercise the corporate-membership option, which ensures that all of their CEs and BMETs are members, receive meeting announcements, and have the opportunity to attend any of the society meetings or special training courses during the year. Some years, membership dues have been included with the annual Symposium registration.

The vendor and membership support from the Northeastern Biomedical Symposia have lightened the financial burden of all four northeastern societies. NESCE's strong financial position allows the executive committee to waive membership dues occasionally, subsidize meetings, and sponsor service schools and training programs each year.

Ongoing Education

To support the biomedical education in Connecticut, NESCE member hospitals have provided practicum experience for biomedical electronics technicians from Gateway Community Technical College (formerly Greater New Haven Technical College) in North Haven, CT, and Springfield Technical Community College (STCC). NESCE members Thomas McGrath and Moshin Matar from Gateway, and Paul Barufaldi from STTC, have been instrumental in educating entry-level BMETs for the profession. Each year, NESCE has provided a \$100 award to the best student biomedical instrumentation design project at Gateway's Annual Symposium. The selected student traditionally has been invited to present the project at a NESCE general meeting and to receive the award at that time.

NESCE also has coordinated educational tours of several local medical equipment manufacturers. General meetings have been scheduled at these facilities with catered meals followed by a tour of the manufacturing plant and presentations by applications, design, production, and quality assurance engineers. Tours have been held at Advanced Medical Systems, Ivy Biomedical, Novamatrix, and Soma Technologies.

Summary

The New England Society of Clinical Engineering has served a vital role in the advancement of the clinical engineering presence in the northeastern United States, significantly raising the bar as a dynamic, high-quality, regional professional society. This is directly related to the contributions of all who have served as officers, helped with symposia, and participated as active members. NESCE recognizes and expresses its appreciation to all of these individuals for their time and talents expended to make NESCE what it has become over the past 27 years.

Unfortunately, NESCE's future is being challenged, as is the case for many regional biomedical professional societies today. As members' hospitals continue to experience increasing financial constraints, and as resources evaporate, the extracurricular activities of the clinical engineering community have suffered significant attrition. Although the actual membership numbers continue to remain strong, the general meeting attendance has diminished significantly, and it grows more difficult each year to find individuals who are willing to dedicate the time, energy, and drive to serve as officers and to maintain NESCE activities.

CEs and BMETs must appreciate that regional clinical engineering professional societies are worthy endeavors and that they must commit to supporting these organizations with their time and talents.

New York City Metropolitan Area Clinical Engineering Directors Group

Ira Soller

Director, Scientific and Medical Instrumentation
SUNY Health Science Center at Brooklyn
Brooklyn, NY

Michael B. Mirsky

Clinical Engineering Solutions
Yorktown Heights, NY

This chapter provides an example of a local clinical engineering organization and describes its goals, history, affiliations, structure, meetings; membership, finances, ongoing education, speaker program, and networking.

Goals

The primary goal of the New York City Metropolitan Area Clinical Engineering Directors Group is to provide a local forum for clinical engineering directors in the greater metropolitan area. This organization provides a venue for the directors to meet periodically to informally address common concerns. Such networking among peers is vital in the ever-changing clinical engineering environment.

In addition to directly benefiting the clinical directors themselves, participation in the group is also indirectly beneficial to the health care institutions that the directors represent. It allows members facing similar business pressures to interact directly with peers, in the same (or very similar) health care provider markets.

A secondary goal of the organization is to provide technical/business presentations, in order to assist the membership in staying current in the clinical engineering field.

Throughout the years, these goals have been met.

History

Dr. Seymour Ben-Zvi (SUNY-Downstate Medical Center) and Walter Buchsbaum (Brookdale University Hospital Medical Center) started the New York City Metropolitan Area Clinical Engineering Directors Group in the early 1980s. By the 1990s, group literature sent to potential lecturers described the group as follows:

“The New York City Clinical Engineering Directors Group consists of 38 directors of clinical engineering departments, representing all of the major medical centers in the greater New York City area. We are directly responsible for managing the medical equipment stock in our respective medical centers. As a group, we are overseeing equipment used for a total of over 25,000 patient beds.

Our group is composed of engineers with various backgrounds and experience. Some have doctoral degrees; while others hold master’s, bachelor’s or associate’s degrees. Some are heavily involved in medical research, while others manage departments that provide a broad range of repair and maintenance services to their facilities. In order for us to keep abreast of this dynamic field, we have group meetings every four to six weeks. A manufacturer or equipment vendor generally sponsors our meetings. A representative from the sponsor provides a technical presentation (definitely not a sales talk) on one of their latest products. The presentation usually lasts about an hour, which includes time for questions and answers.”

AAMI Affiliation

In 1998, the group became affiliated with the Association for the Advancement of Medical Instrumentation (AAMI) when it was granted membership. The organization’s group coordinator serves on the AAMI biomedical organizations committee. This AAMI

committee is open to local, state, national, or international organizations (nonprofit and tax-exempt) representing biomedical equipment technicians, clinical engineers, or related technical service personnel in an educational or related context that have an interest in medical instrumentation.

The Clinical Engineering Directors Group contributed to the AAMI book *How to Establish and Maintain a Local Biomedical Organization* (AAMI, 1999). This contribution included a sample meeting announcement sent to the membership and the meeting sponsor (Figure 132-1); a confirmation letter sent to the meeting sponsor (Figure 132-2); group information and lecture guidelines sent to the meeting sponsor (Figure 132-3); and a press announcement (Figure 132-4).

Structure

This organization has no formal structure. There are no officers or dues. The functioning of the organization relies solely on shared responsibilities. The group coordinator arranges for the technical presentation, and informally coordinates the meetings. The coordinator also maintains the group membership mailing list and is responsible for group meeting notification mailings. Past group coordinators were Dr. Seymour Ben-Zvi (SUNY-Downstate Medical Center) and Paul Fried (Brookdale University Hospital Medical Center). The current group coordinator is Ira Soller (SUNY-Downstate Medical Center).

The director of clinical engineering at the hospital at which the meetings are held acts as meeting host, reserving a room, providing necessary audio-visual equipment, and assisting the sponsor with lunch arrangements. He or she also maintains a book that is used to maintain an attendance list for each meeting. This book serves as documentation should any of the members require proof of continuing education, which might be needed for clinical engineering certification renewal.

All participation in the organization is voluntary. The members contribute as their other commitments allow, often by recommending possible speakers and/or topics for future meetings and providing lecturer contacts based on their own experiences at other technical forums that they have participated in to the Group Coordinator.

Meetings

When the organization first started, the meeting location rotated among member hospitals. At least one meeting was held in conjunction with the post-graduate anesthesiology show in Manhattan. Ultimately, the group settled on St. Luke’s-Roosevelt Hospital Center as the most convenient location for all attendees was due to its central Manhattan location. This location has proven quite successful, due in large part to Michael Mirsky’s efforts both as host and in as substitute group coordinator as required.

The meetings, usually held every six weeks, are scheduled to last for three hours. Initially they were held in the evenings, but the members determined that a weekday afternoon from 2:00 PM to 5:00 PM encouraged the greatest attendance. The meetings are structured to allow for informal conversation, followed by a one-hour technical presentation by an invited vendor or guest lecturer. A formal meeting of group members only occurs after the technical presentation.

MEETING ANNOUNCEMENT

**SCIENTIFIC AND MEDICAL
INSTRUMENTATION CENTER**

January 19, 1999

Dear Colleagues:

The next New York City Metropolitan Area Clinical Engineering Director's Group meeting is scheduled for Tuesday Feb. 9th at 2:00 p.m. in the afternoon. Mr. xxxx and Mr. xxxx of xxxx Corp. will sponsor our meeting. A lecture will be given on "Principles of Operation for Vaporizers". Lunch will be served!

The meeting will take place at St. Luke's Roosevelt Hospital, Roosevelt Division, in the Winston's Conference Room. Enter the new building on 10th Avenue, between 58th and 59th Streets. Take the MAIN elevator to the 1st Floor and walk down the long twisting corridor (toward the Winston building) passing through three sets of doors. Immediately after the third door turn left and stop. Conference Room is on your left.

Parking will be available at a reduced rate in the Medical Center's lot on 59th Street, just West of 10th Avenue in the Concerto Garage. The new building is just a short walk from the lot. Make sure to have your parking ticket stamped by the Security Guard, in the main lobby of the hospital.

Please contact my Secretary, Ms. Emma Johnson via telephone at (718) 270-3192, or by filling in the bottom portion of this letter and faxing it back to us at (718) 270-3194 to confirm your attendance at the meeting. Please respond by Thursday, Feb. 4, 1999.

I wish to thank Mr. Mike Mirsky for acting as host for the meeting, and I am looking forward to seeing all of you there.

Sincerely,

*Ira Soller
Director, Biomedical Engineering*

NAME: _____ <input type="checkbox"/> WILL ATTEND <input type="checkbox"/> WILL NOT ATTEND

Figure 132-1 A sample meeting announcement sent to the membership and the meeting sponsor.

Membership

Membership is open to all practicing clinical engineering directors working in hospital environments in the New York City metropolitan area. In reality, clinical engineering associate and assistant directors and other clinical engineering supervisors also attend. The limitation of membership encourages frank and open discussion. Members come from locations in New Jersey, the five boroughs of New York City, Long Island, Westchester, and other nearby areas. There is no distinction made between directors working directly for a hospital or for a third-party service provider. Manufacturers' representatives and equipment vendors are not permitted to join.

At present, the group includes approximately 80 members on the group mailing list. An updated copy is distributed at each meeting in order to solicit changes. This list is considered proprietary, and is not distributed outside the organization (never to vendors or manufacturers). Typically 20-25% of the membership attends the meetings at any given time.

Finances

The organization has no budget, and thus no need for membership fees, dues, or a treasurer. Group membership in AAMI includes three individual memberships, so the three director's group members selected for the individual memberships split the cost of the \$100 AAMI group membership fee. The meeting room is provided free of charge by the host hospital. The technical lecturers typically underwrite the cost of a modest luncheon,

such as sandwiches and sodas, but participants bring their own lunches when this is not feasible.

Ongoing Education

The technical lecture portion of the meetings provides the membership with ongoing technical and business training. "The environment in which clinical engineering functions changes daily as new technologies such as telemedicine, robotics, and wireless LANs are introduced into the clinical setting. In this dynamic field, continuing education is the rule" (Soller, 1999).

One method of obtaining further education is to attend technical expositions and professional organization meetings such as those of AAMI, the American College of Clinical Engineering (ACCE), the American Society of Health care Engineering (ASHE) and the Institute of Electrical and Electronics Engineers (IEEE) Engineering in Medicine and Biology Society (EMBS). However, as demonstrated by the New York City Metropolitan Area Clinical Engineering Directors Group, a local organization can fill a similar need, albeit on a smaller scale.

Many presentations directly address diverse areas of medical technology, while other topics such intellectual property do not. However, all topics are of importance to the group members. Some recent topics sponsored by vendors are as follows:

- Challenges of monitoring in a MRI environment
- "Controlled fresh gas delivery"

**CONFORMATION LETTER
SENT TO MEETING SPONSOR**

**SCIENTIFIC AND MEDICAL
INSTRUMENTATION CENTER**

Jan. 1, 1998

*Mr. xxxxx xxxxxx
Clinical Sales Specialist
xxxxxxxxx
Fax: xxx xxx xxx*

Dear Mr. xxxxxx:

This note is to confirm that you have agreed to sponsor our next meeting, to be held on Tuesday, Feb. 3, 1998 at 6:00 p.m. The lecture will be a technical presentation on the "Biophysics of electro-surgery, stray energy and electra shield monitoring". The meeting will be hosted by Mr. Michael Mirsky, Director of Biomedical Engineering at St. Lukes Roosevelt Hospital 10th Avenue between 58th & 59th Sts., Phone #212-523-7020 or 212-523-7024. If you need any audio visual aid, Mr. Mirsky will be able to provide it.

A meeting notice specifying room location etc., is enclosed.

Also enclosed is information about the New York City Metropolitan Area Clinical Engineering Directors Group, and a general lecture outline that may be of some help to you.

I am looking forward to seeing you at the meeting.

Yours truly,

*Ira Soller
Director Biomedical Engineering*

cc: M. Mirsky

Figure 132-2 A confirmation letter sent to the meeting sponsor.

GROUP INFORMATION AND LECTURE GUIDELINES SENT TO MEETING SPONSOR

Brief History

The New York City Clinical Engineering Director's Group consists of 38 Directors of Clinical Engineering Departments, representing all of the major medical centers in the greater New York City area. We are directly responsible for managing the medical equipment stock in our respective medical centers. As a group, we are overseeing equipment used for a total of over 25,000 patient beds.

*Our group is composed of engineers with various backgrounds and experience. Some of us have PhD.'s; others Masters or Bachelor of Science Degrees. Some of us are heavily involved in medical research, while others perform more administrative type functions. In order to keep ourselves abreast of this dynamic field, we have group meetings every four to six weeks. Our meetings are generally sponsored by manufacturers who are responsible for making a **TECHNICAL PRESENTATION** (definitely not a sales talk) by an engineer on one of their latest products. The presentation should be about one hour, with questions and answers.*

LECTURE OUTLINE

- 1. A brief history of the development of the type of equipment presented and significant milestones in it's development.*
- 2. A theoretical presentation of the technology used, i.e. type of sensors, transducers necessary for the functioning of your product, one-of-a-kind design features, etc.*
- 3. Physiological indication for and response to your product.*
- 4. A general block diagram of the product with all major component functions.*
- 5. Different technologies used to achieve the same end with pros and cons of each technological solution.*
- 6. Future advances and theoretical limitations (what is on your drawing board now?).*
- 7. Service information (self-diagnostics, board exchange program, service manuals and service support).*

Figure 132-3 Group information and lecture guidelines sent to the meeting sponsor.

PRESS ANNOUNCEMENT

**New York City Metropolitan Area
Clinical Engineering Directors Group**
Ira Soller

The New York City Metropolitan Area Clinical Engineering Directors Group, consists of Directors of Biomedical/Clinical Engineering representing all of the major medical centers in the greater New York City area. The group holds biomed society membership status in AAMI.

At the Feb 9th meeting, hosted by Mr. Mike Mirsky of St. Luke's – Roosevelt, Mr. xxxxx and Mr. xxxxx of xxxx presented a lecture on Principals & Operation of Vaporizers. Subsequent member discussion included sharing of information relating to Y2K including SIIM, and the FDA public health message dealing with use of "protected" patient cables.

The next meeting is scheduled for March 23rd at 2:00 PM. Mr. xxxxx and Mr. xxxxx of xxxxx will give a lecture on "Principles of Volume & Pressure Ventilation including Pathology".

For information, or manufacturers/vendors interested in making presentations contact: Ira Soller, Director of Biomedical Engineering, State University of New York, Downstate Medical Center, 450 Clarkson Ave, SMIC Box 26, Brooklyn, NY 11203. Phone: (718) 270-3192, Fax: (718) 270-3194.

Figure 132-4 Press announcement.

- IEEE 1073 medical information bus
- Infrared technology integrated locator systems
- Infrared thermometry
- Intellectual property
- New modes of ventilation in anesthesia delivery systems, and electronically-controlled fresh gas delivery
- Paperless systems
- Principles of volume and pressure ventilation including pathology
- Robotics and materials transport
- "Technical advances in monitoring"

At the members-only portion of the meeting, members discuss common concerns and diverse topics, a practice that helps them keep pace with changes in regulatory requirements and biomedical standards that impact their operations. The latest JCAHO requirements, FDA recommendations and recalls, and other regulatory issues are all relevant examples of discussion topics. In addition, general issues relating to departmental personnel and financial management, as well as equipment-specific issues, are addressed during this forum. Members might also share information gathered at conferences and lectures or gleaned from professional literature. This friendly and cooperative atmosphere among peers also allows mutually beneficial informal benchmarking.

In addition to the interaction that takes place at the meetings, members frequently contact each other outside of the meetings to discuss management technology or other issues related

to clinical engineering. The group coordinator often acts as a clearinghouse of information, directing member queries to others in the organization who might be able to assist.

Conclusion

When first formed, the New York City Metropolitan Area Clinical Engineering Directors Group promised to provide a local forum where clinical engineering directors could network, and also help them keep current with developments in their field. The group has succeeded in filling both those needs, and continues to function as a viable organization, providing support at a local level.

Clinical Engineering Certification in the United States

Thomas Nicoud

Design Planning Information
Tempe, AZ

Eben Kermit

Biomedical Engineer and Consultant
Palo Alto, CA

The first question one must ask is, “Why pursue Certification as a Clinical Engineer (CCE)? What value is a CCE?” The answers are complex, for if one were to ask a dozen clinical engineers why they became certified, one would get a dozen different responses. In the late 1990s, the number of individuals seeking certification declined, leading to the abandonment of the certifying program by the organization that served as the secretariat for the process, the Association for the Advancement of Medical Instrumentation (AAMI). AAMI continues to manage a renewal program for those previously certified clinical engineers who wish to remain affiliated with the former certification program.

The American College of Clinical Engineering (ACCE) has developed a replacement process for certification. (For a description of the ACCE initiative, see Chapter 130.) This chapter describes prior certification programs up until the time the process was discontinued by the AAMI. The history and rationale for establishment, as well as the application for, examination in, and renewal process of, clinical engineering certification is reviewed.

A Brief History

The 1960s saw the space race, the invention of the integrated circuit, and headline news about the number of patients who were being electrocuted in hospitals. Resistor-Transistor Logic (RTL) and Diode-Transistor Logic (DTL) devices arrived and were succeeded by Transistor-Transistor Logic (TTL). Operational amplifiers became solid state, and the Digital Equipment Corporation’s PDP series of minicomputers were powerful new tools featuring 8K core memories and Teletype ASR33 units as I/O devices. A Computer of Average Transients (CAT) was a (nuclear channel analyzer—256 words—used for evoked response studies) then. Graduate-level programs in Biomedical Engineering began to appear. In 1971, Ralph Nader wrote an article that appeared in the *Ladies Home Journal*, citing unsubstantiated claims that 1200 people per year were electrocuted by medical devices.

Electronics for Medicine (“E for M”) was a dominant supplier of catheterization laboratory physiological data recorders, and Statham was the prevalent provider of blood pressure transducers. Herb Mennen and Wilson Greatbatch teamed up to create Mennen Greatbatch. Sanborn Instruments was absorbed to become the core of Hewlett Packard’s medical division. General Electric began producing implantable pacemakers.

In 1969, AAMI held its fourth annual meeting in Chicago as a joint event with the 8th International Conference on Medical and Biological Engineering and the 22nd Annual Conference on Engineering in Medicine and Biology. Nine years later, the Safe Current Limits for Electromedical Apparatus Standard (ANSI/AAMI SCL 12-78) was adopted.

Rationale for Certification

The 1970s was a time of rapid technological change, but health care was having difficulty coping. Perhaps the situation can be painted by a set of paraphrases and quotes from a paper titled “The Horror of Common Practices” by John MR Bruner in the *Electric Hazards in Hospitals Workshop* (April 4-5, 1968) (Bruner, JMR, 1970). The paradoxes of modern medicine form the basis of this horror.

- First, the electrical environment is in the hands of the least competent people.
- Virtually no attention is given to electrical safety education—even in teaching hospitals.
- In a sea of information, the real data (about incidents) are missing or hidden.
- Expediency in care overrides consideration of patient welfare.
- Buildings, which house medical practice, are antiquated.
- Innovation has been pushed, while the basics have been ignored.

A number of people from a variety of backgrounds were enlisted by health care organizations to address these basic issues, as well as to assist in the ongoing diffusion, development, and refinement of the technological tools. The term “clinical engineer” is believed to have been coined by physician Cesar Caceres in the early 1970s.

Certification was seen as a means of identifying and recognizing persons who have common skill sets, who have been demonstrative and successful in the applied technology (in direct patient care) arena. Under the auspices of AAMI, the Commission for Clinical Engineering and Biomedical Equipment Technology was established as the official body to oversee the application, examination, and renewal process and to confer the “certified” designation. Biomedical equipment technicians (BMETs) were the first to be examined and certified (“CBET”) in 1972. Many had been trained formally and had acquired extensive experience in the U.S. Armed Services, (primarily the Army and Air Force), performing medical equipment repair.

Clinical engineers were a different matter. There were few formal training programs or academic degree programs in clinical engineering. Clinical engineering was still poorly defined, and no professional organization existed to define and promote clinical engineering and to educate and guide clinical engineers. Biomedical engineering organizations existed, but this broad discipline did not focus specifically on the application of engineering to medical device technologies in hospitals. In fact, biomedical engineering was then (and, to some extent, still is) seeking to promote an increased awareness among professionals and the general public of its identity and its role in society.

Rather than defining a specific skill set as a starting point, a group of practitioners who best fit the image were identified and deemed “certified” by the Certification Commission in 1975. These individuals became certified without examination in a process referred to as “grandfathering” (i.e., granting certification on the basis of extensive experience in the profession as demonstrated by work experience, education, publications, and general contribution to the field). Most references indicate that the number of grandfathered clinical engineers was 49. This core group became the model for skill set identification and testing.

At the time of the formation of the AAMI-based commission, another clinical engineering certifying body existed, known as the American Board of Clinical Engineering (ABCE). This entity was not sponsored (i.e., supported) by any other organization. It was sustained by the efforts of its volunteers and placed a heavy emphasis on formal engineering credentials. It differed in its lack of willingness to accept engineering credential equivalencies and in its willingness to accept funding from any single organization that might influence any aspect of its decision making.

By the end of 1977, 196 individuals were certified as clinical engineers by the Certification Commission. In 1983, the ABCE and the Certification Commission agreed to dissolve and to form the International Certification Commission for Clinical Engineering and Biomedical Technology (ICCCEBT, or ICC). Within the ICC, various country certification commissions were created; e.g., the United States Certification Commission (USCC) and the South African Certification Commission (SACC). By June, 1997 the meeting minutes of the U.S. Board of Examiners for Clinical Engineering noted that individuals 467 were certified in clinical engineering. Of those, 293 had been certified by the Certification Commission, and 50 had been certified by the ABCE prior to the merger into the ICC in 1983. Fifty had been certified by the Canadian Board of Examiners for Clinical engineering. By June 1999, the number had risen to 474.

Process

Based on the name “clinical engineering,” it was not surprising that the process that was used as a model for certification in the United States was that used by the states in the registration of professional engineers. Engineering was a common element in the skill sets of the group first certified. It was a focus for credentialing by the ABCE. In addition, Canada required that any individual who was designated an “engineer” must be a registered “Professional Engineer” (PE). Thus, being certified as a PE became a prerequisite for Canadian certification. In an international context, it would have been

difficult for the United States to be a leader without a credibly analogous focus on engineering (albeit lacking the PE registration requirement).

Three basic elements were involved in the ICC program: The application, written examination, and oral interview. Under the ICC, from 1983 through 1999, the process of becoming certified involved a lengthy application, including documentation of education (i.e., transcripts and diplomas, with a Bachelor of Science degree the minimum acceptable credential), and a listing of inventions, books, patents, journal articles, and meeting presentations. There was also a review of work history and evaluations by at least three supervisors or managers. A written statement of why certification was of value to the applicant, and ways in which certification would benefit the hospital or employer, was required. An application fee (in U.S. dollars) was necessary to offset the cost of administration. A history of at least five years in medical-related engineering work was another minimum requirement.

Information was conveyed to, and documented by, the certification applicant on the multipage application form. The preface to the actual data form contains sections addressing general information (including the definition of a clinical engineer), eligibility requirements, the certification process, certification renewal, available readings (reference books), and sample questions. Required data focused on the applicant's formal education and relevant professional experience. The experience section calls for references (from which written response is to be solicited by the Board of Examiners) and essay responses detailing experience and accomplishments.

Applicants who satisfy the eligibility requirements of the application, as determined by review of the submitted information by a panel of three members of the Board of Examiners, could request scheduling of the written examination. While most frequently these examinations had been administered in conjunction with the AAMI Annual Meeting, other arrangements were sometimes made to offset travel hardships or logistics problems. The test included 150 multiple-choice and true/false questions covering a number of subjects in the basic areas of medical science, clinical engineering, and engineering. Questions were drawn from a question bank on areas ranging from anatomy and physiology to regulatory issues, hospital practices, and engineering. The United States Board of Examiners (USBE) was responsible for the maintenance of this question bank, continuously updating it to keep pace with changes in technology, regulations, and practice. Three and a half hours were allowed for this portion of the examination. The last portion of this examination consisted of essay responses to five questions out of eleven. Two and a half hours are allowed for this portion. Correct multiple-choice questions carry a point value of one; the essay questions carry a maximum point value of ten. The minimum overall passing grade is 60% with a minimum of 50% in any one area.

Successful completion of the written examination qualified the applicant to take the oral interview. Like the written exam, this interview was most frequently administered in conjunction with the AAMI Annual Meeting. At least two members of the Board of Examiners conducted this interview, evaluating the candidates' experience, their thinking skills, and their ability to demonstrate good judgment in hypothetical scenarios. The interview usually lasted an hour and focused on the applicant's ability to make judgments on engineering issues. It also was partially devoted to clarifying abilities that appeared to be notably weak on the written exam. This last element was perhaps the most important, and the least objective to evaluate. Each examiner prepared an independent recommendation for certification, following the interview. If both examiners agreed, certification was recommended to the chair of the Board for subsequent submission to the ICC for granting of certification. If both concurred negatively, certification is not recommended. Lack of agreement between the two examiners required review by the full Board of Examiners. On rare occasions, re-interview by a different interview team conducted.

Recommendations regarding certification were conveyed to the members of the ICC at the annual meeting, which also was held in conjunction with the AAMI Annual Meeting. These recommendations were discussed and formally endorsed, as deemed appropriate by the members, for transmittal to the applicant through the Secretariat (i.e., AAMI).

For a variety of reasons, applications for certification declined precipitously in the late 1990s, the program became more difficult to support financially, and AAMI discontinued accepting new applications for certification in 1999.

Renewal of Certification

Renewal and/or recertification was considered for implementation (and actually communicated via letter) by the chairman of the Board of Examiners (Thomas Hargest) to all CCEs on December 20, 1977. The letter read, in part:

"At the March 1977 meeting of the United States Board of Examiners for Clinical Engineering Certification, it was decided that those clinical engineers originally certified in March 1975 and March 1976 will be eligible for recertification in March 1979. After the latter date, recertification eligibility will occur at three year intervals."

A renew policy was adopted 1992. It states that applicants certified after 1992 who do not renew can be revoked but those who were certified before 1992 will become delisted. As of 2002, the AAMI web site "listed" fewer than 100 CCEs.

The Value of Certification

Given that demonstration of competency in the field of clinical engineering, and knowledge of medical devices, hospital practice, and regulatory affairs are important, why, then, has the certification process been foundering? In many other professions, the ability to demonstrate professional competence or proficiency is accomplished by a certification examination or a license, and is common practice. Lawyers, psychologists, FAA airframe mechanics, and certified public accountants (CPAs) are used here as examples of professions that require certification. All have an infrastructure for demonstration of competency requirements via examination prior to practice in their respective fields.

This was the thought process or impetus for the creation of the CCE title. The CCE examination was a peer review process to qualify individuals by a review of education, training, experience and critical thinking. Job placement, project assignments and professional activities were often determined (either included or excluded) based on CCE standing. Yet, the need for certification did not flourish.

Engineers continue to provide a much-needed and highly valued service to the health care field. However, it is possible, even typical, to work in the field of clinical engineering without a formally recognized degree or specialized training. This increases the likelihood of accidents, misuse of medical devices, and substandard maintenance and repair of equipment because of a lack of experience, training, and expertise. There is a reason why physicians attend medical school, why pilots take written and simulation exams, and why truck drivers must pass a proficiency test before they can haul freight. It makes sense for clinical engineers to follow the pattern set by other professions and to create a peer-peer approval process to ensure that clinical engineers continue to provide good advice, management, and safety to the health care profession.

The Future

The American College of Clinical Engineering (see Chapter 130) began a comprehensive approach to reinstating certification in 2000. The program also created a window of opportunity for recognition of persons certified under the AAMI program.

Since entrance requirements, duration, curriculum, examination, and quality assurance of all educational institutions leading to a certified profession are government-regulated in Germany, an additional professional certification has not been necessary. Nevertheless the Deutsche Gesellschaft für Biomedizinische Technik e.V. founded a certification system for clinical engineers, and the Fachverband Biomedizinische Technik e.V.—the professional association of clinical engineers in Germany—is preparing a certification system for technicians. This chapter describes these programs.

General System of Professional Certification

To date, a system of professional certification by non-government certification institutions such as professional associations is nearly unknown in Germany. A professional proves his or her knowledge, ability, and experience in the following ways:

- A certificate from educational institutes attesting to successful completion.
- A certificate/references from a former employer.
- Written confirmations of attendance at courses, seminars, and workshops, issued by the organizer
- A personal statement or report.

A certificate, issued by an institute of education, is acknowledged only if the institution is affiliated with or certified by the government. Primary and secondary schools, vocational training institutes, technician education programs, and each course of study at every university require recognition by the respective ministry. Thus, subjects, quality, and duration are officially controlled. A university degree can not be obtained without passing all obligatory examination in the course, and no exceptions are possible.

Someone who lives in Germany and wants to use an academic degree obtained at a university abroad must request permission from the ministry of culture of the state where he or she lives. Fortunately, all degrees from recognized universities in Europe are acknowledged in every other member country of the EU.

Every employee has the right to obtain a written reference from his former employer upon leaving a job. This reference must contain the facts of the employment, i.e., the beginning and ending dates of employment, the position held, and the tasks performed. This is called an unqualified reference. A qualified reference includes a description of the tasks, plus statements concerning the quality of work, conduct, and managerial and supervisory skills. However, the legal prohibition on obviously negative statements is a problem. That is why all judgments are pronounced positively in a scale from satisfactory (meaning rather bad) to excellent. A written or oral reference from the former employer addressed to a future employer is very unusual.

An acknowledgement of the university certificate is necessary for certain jobs (e.g., physician, lawyer, or architect) or positions (e.g., teacher at a certified school or high level government officer). Employer and employee are both responsible for ensuring the necessary qualification of the employee.

Requirement of Certification in Clinical Engineering

In the clinical engineering field few tasks officially require special education, training, or experience. The following are examples:

- Radiation protection in radiotherapy: The so-called expert in medical physics must hold a degree in physics or engineering, prove knowledge in medical physics, obtained in certified courses, and possess experience on the job.
- Maintenance, safety checks, calibration of medical devices: The German directive for operation of medical devices (VEBAM, 1998) demands a suitable education plus prac-

tical experience. The owner of a medical device, who gives the order, and the person executing the order for device use are both responsible for the necessary qualification. However, a defined certificate is not required.

The start of calibration work on medical devices with measuring functions must be announced to the trade-supervisory board. This board has the right to check for personal qualifications and for adequate experience with equipment and procedures, but no formal certificate of qualification is required.

A private workshop for repair of electrically driven—not necessarily medical—devices must be registered at the local chamber of handicrafts. The responsible person must hold a certificate as “Meister” in electrical craftsmanship or prove an equivalent qualification. A degree in clinical engineering including proof of knowledge in electrical engineering is an example of equivalent qualification.

- A medical devices’ consultant (i.e., the sales person who informs and instructs the owners or users of medical devices) must have a scientific, medical, or technical education, plus instruction by the manufacturer or one year of relevant professional experience (GM, 1994). A special certificate is not required.
- According to the German law on medical devices (GM, 1994) a manufacturer or importer of medical devices must appoint an authorized person to handle all safety information and act as liaison with the authorities. This person informs the government authorities about the hazards of medical devices. He or she must have a university degree in engineering, science, or medicine, or the equivalent plus a professional experience of at least two years. A special certificate is not required.

Certification by the Biomedical/Clinical Engineering Associations

Though neither the law nor employers ask for a certificate in clinical engineering other than a diploma from an educational institution, most of the biomedical engineering associations offer an additional certification or are planning to do so.

Certification of Clinical Engineers

Since the 1980s, the German Biomedical Engineering Society (Deutsche Gesellschaft für Biomedizinische Technik e.V., or DGBMT) has offered a certificate in accordance with the statutes of the International Federation of Medical and Biological Engineering (IFMBE). At the moment, the regulations of 1999 are in effect, requiring the following:

- A university degree in science or engineering
- Knowledge of German and English language
- Proof of professional practice in a biomedical environment
- Theoretical knowledge in at least six subjects from a catalogue, gained in at least 360 hours of lectures. Two of the six subjects must be medical, and one must be in the organizational field. Each subject must include at least 20 hours of lectures.
- Catalog of Subjects:
 - Medical subjects:
 - Physiology
 - Anatomy
 - Hygiene
 - Emergency medicine
 - Technical subjects:
 - Biomaterials and artificial organs, clinical dosimetry and radiation therapy planning, radiation protection
 - Clinical laboratory and analytics

Biosignal processing
Electromedicine and medical measurement
Imaging
Computer science in medicine
Statistical methods
Biomechanics
Organization and law
Technical safety and quality assurance in medical engineering and medicine,
Clinical trials
Approval of medical devices according to law

The candidate may propose additional subjects. Proof of knowledge requires certificates issued by certified institutions, based on appropriate oral or written exams.

Persons with at least eight years of practical experience in the clinical engineering field but without a degree may also apply for certification. They must pass an oral examination in four additional subjects from the catalogue, which takes at least two hours. A failed exam may be repeated once per year.

Certification of Biomedical Engineering Technicians

The German professional association of clinical engineers, Fachverband Biomedizinische Technik e. V. (FBMT), plans to introduce a certification system for skilled craftsmen and technicians working in the field of clinical engineering. Details on requirements and procedure will be published on the Internet: www.fbmt.de.

Section XIII

The Future

Jennifer C. Ott

Director, Clinical Engineering Department
St. Louis University Hospital
St. Louis, MO

At times it is overwhelming what can encompass the field of clinical engineering, a field that is as dynamic as the people in it. Those who understand the concept of clinical engineering get it, however, it is the transposition that is the constant struggle. Every clinical engineer has had to explain the profession at one time or another. The American College of Clinical Engineering (ACCE) definition provides a clear concise explanation that can then be tailored to the specific role: Clinical engineers support and advance patient care by applying engineering and management skills to health care technology.

In reviewing the chapters for this section I am in awe of where we have been, where we are, and where we can go. There are so many clinical engineers out there it is amazing. The goal is to have the non-traditional ones consider themselves part of the clinical engineering field. This handbook is a large step in accomplishing just that by linking all the specialties of clinical engineering under one cover.

This section focuses on the many avenues clinical engineers can explore to further their skill set or embark on a new career path that utilizes their ability of combining engineering and health care technology. The authors have done a wonderful job of exploring future opportunities while maintaining the core of the clinical engineering discipline. The initial chapter has the responsibility of reviewing the technical advances and how clinical engineers can apply themselves to their success. I found the concept of the *Inflection Point* to be very insightful and right on the mark for the development of future generations of clinical engineers. It is interesting that the avenues explored for the future roles really support the skills and continue them to the next level. In the following chapter, virtual instrumentation as applied to health care is illustrated by several practical examples (see Chapter 136). The next chapter covers historical and future non-traditional clinical engineering roles with a humorous entrance in which many traditional types may have to look in the mirror! The success of applying engineering skills for the improvement of health care is embodied in many careers that really are clinical engineers by definition but not typical or historical environment.

The following chapter (Chapter 138) on SWOT analysis takes inflection to the military-engineering level. SWOT stands for strengths, weaknesses, opportunities and threats. The

results make you think how this applies in your particular career path. The author is very resilient and still on the cutting edge in the field with design in the health care setting.

Clinical engineers and biomedical engineering technicians have the capability and knowledge to assist with the user representation of the Global Harmonization Task Force and in particular their capacity to provide key information in post market surveillance and vigilance of medical devices. This role has always existed but behind closed doors, yet with the current trends in reporting and the required ending of the punitive aura of medical device mishaps, the clinical engineer is at a unique vantage point to fulfill this role quite well (Chapter 139).

Every clinical engineer can add a new tool to their managerial toolbox especially an outline to succeed and sell your future. Business plan development is a special skill and one often overlooked by the technical set. The author provides the fundamentals to assist anyone in breaking down the necessary parts to make your future successful (Chapter 140).

Reviewing an actual case study showing how clinical engineers affect the quality management of a primary health care concern (Chapter 141) expands the potential future of the profession. The technical skills of a clinical engineer can cross many paths including part of a health care delivery team in researching disease management. This is truly an avenue that is not explored enough within the resources of the health care community. The closing chapter (Chapter 142) blasts through the eighth dimension to 2050. The trends are certainly justified by looking at health care today. The role of the clinical engineer still has a place in 2050 as the meshing of engineering and health care technology continues plus the fact that the world is becoming a smaller place.

In addition to exploring the many potential futures of clinical engineering this section highlights the important role that clinical engineering will have for many years. Often it is difficult for technical people to see outside the box and assume a metamorphosis in their role. Staying within the traditional clinical engineering role will not slow the future just temporarily mask and one can only embrace the excitement of what is to come. The future is very bright for the field of clinical engineering so put on your shades and hold-on tight for what is sure to be an exciting ride. I look forward to the journey and hope to see you in the future.

The Future of Clinical Engineering: The Challenge of Change

Stephen L. Grimes

Senior Consultant and Analyst

GENTECH

Sarasota Springs, NY

"It's not the strongest of the species that survives, nor the most intelligent, but the one most responsive to change." —Charles Darwin

"It's not the progress I mind, it's the change I don't like." —Mark Twain

"Change is good. You go first...."—Dilbert

What will the future of clinical engineering look like? The question is an important one for clinical engineers to consider because the answer determines how they should be preparing now for that future. What level of education and what skill sets should be acquired? Anticipating the future enables us to effectively prepare to be proactive, rather than reactive, as changes take place in our industry.

To reasonably predict the future role of clinical engineering, we must consider the future nature of health care. Clinical engineering services evolve within the context of our health care delivery system. Consequently, significant changes in health care delivery are likely to result in a corresponding need for changes in the character of clinical engineering services. This chapter provides an overview of the changes in health care, the forces affecting those changes, and recommendations for clinical engineers to adapt and prosper in the environment to come.

Clinical Engineering's Future Linked to Developments in Health Care

We must recognize that there are revolutionary changes occurring within the health care delivery system. These changes are the results of a combination or confluence of technological, economic, cultural/demographic, and regulatory forces. Clinical engineering's ability to contribute, or perhaps even survive professionally will depend on how effectively it adapts to the changes brought about by these forces.

Technological Forces

Today we have the human genome mapped. As we continue our research in this area, we gain the ability to screen and identify individuals who possess genes that predispose them to certain diseases. Knowing who is predisposed to various diseases will enable us to focus our preventive efforts on those who are most at risk. Our understanding of the genome will enable us to refine our treatments. We will have the ability to develop some treatments that target affected genes while still other treatments can be optimized for an individual patient, based on what we know to be effective for someone of their genetic make-up.

Significant scientific developments have been occurring in the areas of micro- and nanotechnology (Fonash, 2002). Nanoparticle vectors are being developed to aid in drug delivery and DNA modification. Micro- and nano-scale devices are being designed to function as artificial organs and surgical instruments. Micro- and nano-sensors under development can serve as probes and detectors at an organ, tissue, cellular, or even molecular scale-level. These technologies are designed to be minimally invasive, and minimally disruptive, and to mimic the body's own natural systems closely.

Information technology promises to play a greater role in the business and the clinical aspects of health care. As a consequence of our ability to use technology to gather more data about a patient's condition, there has been a corresponding need to process that information in a way that is meaningful to the diagnostician and therapist.

The capability and availability of the integrated circuit have dramatically increased since personal computers appeared in the early 1980s. Over that period of time, the processing power of the computer has roughly doubled every 12 months. While the processing capability of each new generation of computer has grown exponentially over the past 20 years, the relative cost of those systems has dropped by half in the same period. In 1981, an IBM PC with a 4.77 MHz 8088 with 64Kb of RAM and 320Kb of storage sold for about \$3,000. A typical system in 2001 with a 2 GHz Pentium 4, 512Mb of RAM, 120Gb of storage also sold for approximately \$3,000, but that is equivalent to \$1,454 in 1981 dollars.

Growing capabilities and the falling cost of integrated circuits have led both to the proliferation of computers in medicine and to the widespread adoption of those integrated circuits in medical devices and systems. Incorporating these technological advancements has greatly increased the amount of diagnostic and therapeutic data that these systems can collect, store, and process. Further, it is spurring the development of a broad array of experience and knowledge-based expert systems—systems that are designed to collect data and to suggest diagnoses and courses of treatment based on "pre-selected rules for decision making within specialized domains of knowledge (Frenster, 1989)." In medical devices and systems, these advancements have had the added benefit of improving system reliability and incorporating self-diagnostic capabilities.

Connectivity is another trend that is rapidly transforming the health care technology landscape. The number of diagnostic, therapeutic, and expert systems being linked is on the rise. Clinical information systems are also tying into the business-oriented hospital-information systems. The overall effect is synergistic, where the benefits gained from integrated systems far exceed the benefits available when the individual devices and systems are used in their stand-alone mode. Connectivity has also been advancing at another level. Networking and the Internet have the potential to bring health care resources to any near or remote location and to facilitate medical data and personal (i.e., voice & video) communications among a combination of patients, providers and payors.

The information technology industry is moving toward the development of what IBM calls "autonomic" systems (IBM, 2001; Gibbs, 2002). Like the involuntary nervous system that allows the human body to adjust to environmental changes, external attacks, and internal failures, future autonomic technical systems will:

- Be self-aware
- Adapt to environmental changes
- Continuously adjust to optimize performance
- Defend against attack
- Self-repair
- Exchange resources with unfamiliar systems
- Communicate through open standards
- Anticipate users' actions

The use of autonomic systems will enable us to realize the benefit of increasingly complex technologies that, without their autonomic abilities, would quickly overwhelm us with their needs for management and support.

We have just identified several key technological developments affecting health care. These have included the mapping of the human genome, advancements in micro- and nanotechnology, the exponential growth in information processing capacity and availability, the connectivity of technologies, and, finally, the introduction of autonomic systems. These are emerging medical technologies that have the potential to greatly improve the quality and availability of health care, and to so at a reasonable cost. (George, 1999)

As powerful forces for change, these emerging technologies will likely be critical in determining the future role of clinical engineering.

Economic Forces

The U.S. health care industry is experiencing a financial crisis. U.S. health care costs have been spiraling out of control for the past 10 years. In 1997, 13.5% of the U.S. gross domestic product (GDP) was spent on health care (considerably higher than Germany, Switzerland, and France, whose spending is the next highest as a percentage of their GDP, at 10%) (Health Forum, 2002). Total U.S. health care expenditures rose from \$888 billion in 1993 to \$1425 billion in 2001. Those expenditures are expected to grow to \$3.1 trillion and 17.7% of GDP by 2012. (Heffler, 2003). Spending on health benefits for their employees cost American companies \$177 billion in 1990, and by 1996 the amount had soared to more than \$252 billion (rising at more than twice the rate of inflation) (PBS, 2000). Health insurance premiums increased by 11% in 2001—the fifth straight year of rising premiums, and the highest increase since 1993 (CSHSC, 2000). The U.S. now spends more money on health care than any other nation, but its care ranks 37th in quality, according to a recent World Health Organization survey of 191 countries (WHO, 2001).

One study, reported in the *New England Journal of Medicine* found that 19–24 percent of U.S. health care expenditures go for administrative costs (Woolhandler, 1991). This figure sharply contrasts with that of Canada, where it is estimated that administrative costs represent only 11% of total expenditures, and most European countries, where the average is 7%.

Adoption of new technologies has significantly contributed to industry cost increases. One recent study estimated that between 1998 and 2002, new medical technology contributed 19% of the increases in inpatient health care spending (Hay et al., 2001). Another recent study, conducted by the University of California at Berkeley researchers on the true total cost of ownership (TCO) for computer-based systems, calculated that TCO the first three years after acquisition now represents between 3.6 and 18.5 times the initial purchase cost of hardware and software (UC Berkeley, 2002). The same study suggests that “a third to half of TCO is recovering from or preparing against failures.” Without innovative design (e.g., autonomic systems) and careful management, the disproportionate relationship between the initial purchase and ongoing support costs will only increase as new and more complex technologies are adopted.

Clearly, these trends cannot continue if we are to have a healthy economy and a first-rate health care industry. We must find a means of reducing costs for the level of health care that we are receiving. If we cannot reduce these costs, we must be prepared to adjust our expectations and to settle for the level of care that we can afford.

Demographic/Cultural Forces

The U.S. is undergoing significant cultural and demographic changes that will have an important impact on the health care industry. Within the next decade, the “baby-boomers” will begin reaching the age of retirement. Between 2011 and 2030, the number of Americans age 65 and older will jump from 13% to over 20% of the total US population (U.S. Department of Commerce, 2000). As this group reaches age 65, they can look forward to the prospect of living much longer lives than previous generations did, due to advancements in medical science and technology. Due to the aging population, there will be a growing shift from acute, episodic care to care for chronic conditions (Institute of Medicine, 2001). Currently, 100 million Americans are treated for chronic conditions. Of them, 40% have multiple chronic conditions (Guralnick et al., 1989). Today, the medical care costs of people with chronic diseases account for more than 60% of the nation’s medical care costs (Centers for Disease Control and Prevention, 2003). By the year 2020, 157 million Americans will have a chronic condition, and 80 percent of the country’s total medical care spending will be associated with treatment of these individuals (Wu and Green, 2000). As a consequence of these trends, we need to be concentrating most of our efforts on the development of a health care system that provides long-term treatment programs for patients with multiple, chronic diseases.

Given their exposure to advances in technology and the Internet, today’s consumers are better informed and have higher expectations regarding health care quality and availability than any previous generation. These consumers will demand that industry and government work together to ensure that quality health care is readily available at a reasonable cost. As the U.S. population looks forward to a longer lifespan and the prospect of long-term treatment for chronic diseases, the availability of effective and affordable health care becomes a critical quality-of-life issue.

Regulatory Forces

In recent years, issues related to health care quality and costs have led to government and industry initiatives directed at improving the quality and availability of health care, and at reducing its costs. In the early 1990s, a respected industry group reported to Congress that \$73 billion per year could be saved if health care organizations would adopt the use of standardized data formats to exchange patient information (Duncan et al., 2001). Congress reacted by including the administrative simplification provisions in the Health Insurance Portability and Accountability Act (HIPAA) and passing this legislation in 1996. In the HIPAA legislation, the U.S. Department of Health and Human Services (HHS) was directed to develop regulations requiring health care organizations to adopt the use of standardized data, to ensure privacy of patient-related health information, and to implement safeguards to ensure the integrity, availability, and confidentiality of those data. The various provisions of HIPAA were scheduled for implementation between 2002 and 2005. Adoption of these provisions should help to facilitate the exchange of data between a rapidly growing array of information and biomedical technology systems.

In 2001, the Institute of Medicine (IOM) released its watershed report, *Crossing the Quality Chasm: A New Health System for the 21st Century*, which examined the state of the U.S. health care system (Institute of Medicine, 2001). That report details recommendations for the industry, including a number of major recommendations on “applying advances in information technology to improve clinical and administrative processes.” In fact, many of the report’s main recommendations can be accomplished only through the effective integration of information and clinical or biomedical technologies. A year earlier, the IOM had released another major report, *To Err Is Human: Building a Safer Health System*, which suggested that as many as 98,000 Americans die annually as the result of medical errors (Kohn et al., 2000). In that report, the use of increasingly sophisticated and complex technologies is cited as a contributory factor in many of these errors. The report goes on to assert that technology must be recognized as a member of the health care team and that among its roles are enhancing human performance and automating processes so as to remove opportunities for humans to make errors. However, system failures can occur, and where technology is employed, humans still must find ways to effectively monitor the processes that they automate. Both of these IOM reports have had a major impact on the health care industry and are very likely to influence federal legislation and industry initiatives for the foreseeable future.

In 1999, an industry-sponsored initiative called “Integrating the Healthcare Enterprise” (IHE) was launched. IHE brought together medical professionals and the health care information and imaging systems industry “to agree upon, document and demonstrate standards-based methods of sharing information in support of optimal patient care (RSNA, 2001).” The initiative was sponsored by the Radiological Society of North

America (RSNA) and the Health care Information and Management Systems Society (HIMSS). After successful efforts in medical imaging, this program is now attempting to broaden its scope into clinical laboratory, cardiology, and other areas that would benefit from the effective integration of biomedical and information technology systems.

HIPAA, the IOM reports, and IHE represent perhaps the most significant regulatory and pseudo-regulatory initiatives impacting the adoption of technology in the health care industry in current times. As we look to technology to help address of health care’s growing number of problems and issues, they undoubtedly will turn out to be only the precursors of many future initiatives.

Net Impact of these Forces

Because of the forces described above, health care in the U.S. will undergo substantial changes within the next 5–20 years. The health care industry will focus increasingly on the long-term treatment of chronic conditions for an aging patient population. This population will expect high-quality care that is both readily available and reasonably priced. Technological advances will facilitate the industry’s ability to meet these demands, and regulatory pressures will foster better integration.

Strategic Inflection Point for Clinical Engineering

Andrew Grove, Intel’s chairman, defined “strategic inflection point” as a term that describes the time in which extreme forces forever alter the landscape of an industry, creating opportunities and challenges (Grove, 1999). In Grove’s model, businesses and industries progress along a steady, smooth fashion until hitting a subtle point where the business dynamics force a change in the curvature of that progression. At this “inflection point,” the transition is so smooth and subtle that there are no obvious profound, major, or cataclysmic signs. However depending on the actions it takes, a business will progress through the inflection point along a path to potentially unprecedented heights, or it will find itself going down the path toward obscurity. If a business misses the opportunity and begins the descending branch of the curve, it is exceedingly difficult to reset the progression and to correct for the action not taken at the inflection point. It is, therefore, extremely important to anticipate and to act before reaching that inflection point.

Clinical engineering programs, and perhaps the profession, are arriving at a strategic inflection point, as shown in Figure 135-1. The long-term viability of clinical engineering as a distinct profession and service depends on the model that clinical engineering programs adopt for the future. Selecting the right model ensures clinical engineering’s future role as a successfully productive and important element in health care. Selecting the wrong model will result in a declining role until other technical-service programs assimilate any clinical engineering function that remains.

Historical Perspective

Clinical engineering encountered another strategic inflection point in the past. Beginning in the mid to late 1960s, hospitals began to significantly increase their adoption and use of biomedical instrumentation. In 1970, the consumer activist Ralph Nader wrote an article for the *Ladies Home Journal*, claiming that at least 1200 Americans were electrocuted annually in hospitals during routine diagnostic and therapeutic procedures (Nader, 1971). The Emergency Care Research Institute (ECRI), a nonprofit organization evaluating the safety and effectiveness of medical devices, reported that “a disturbing proportion of ... medical devices is demonstrably ineffective, of inferior quality, or dangerous.” Approximately half the new medical devices being purchased and delivered to hospitals were defective to some degree (Health Devices, 1971). ECRI’s reports of medical equipment quality issues, along with Nader’s comments on electrical safety, served to raise public interest, and a series of congressional hearings were subsequently held on medical device safety. Over the next five years, the U.S. Food and Drug Administration (FDA), the Joint Commission on Accreditation of Hospitals (JCAH), the National Fire Protection Association (NFPA), Underwriters Laboratories (UL), the Association for the Advancement of Medical Instrumentation (AAMI), and many states adopted standards or regulations pertaining to the design, manufacture, and/or testing of medical devices.

During this period, the combination of the rapid adoption of new technologies, rising public concerns about safety, and the promulgation of regulations resulted in the occurrence of an inflection point. This inflection point would have a significant effect on the

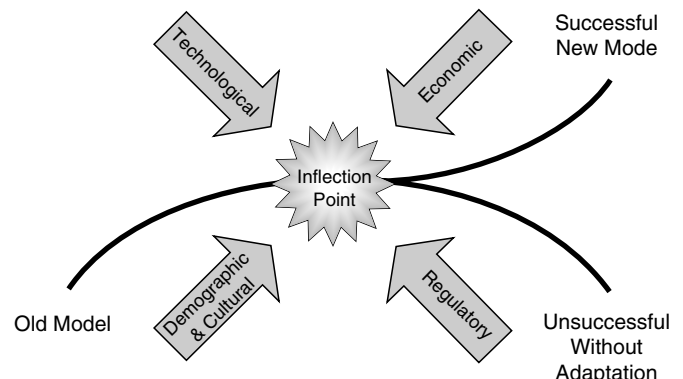

Figure 135-1 Strategic inflection point in clinical engineering programs.

growth of the relatively new field of clinical engineering. Few of the nearly 7000 U.S. hospitals had clinical engineering programs in the early 1970s. By 1975, JCAH (the largest hospital-accrediting organization in the U.S.) had established a requirement that hospitals conduct incoming inspections of all new medical equipment and perform routine electrical-safety testing of all medical equipment used in their facilities. When this inflection point occurred in the early 1970s, there were many opportunities for those individuals and businesses that were qualified and prepared to deliver biomedical equipment services. Larger hospitals employed clinical engineers and biomedical equipment technicians to develop and operate in-house medical equipment management programs. Smaller hospitals that could not afford to hire dedicated staff typically contracted with clinical engineering service organizations to obtain their medical equipment services.

The primary focus of clinical engineering services in the early years was on incoming and routine inspections (with an emphasis on electrical-safety testing) and on repairs of biomedical equipment. While clinical engineering's role over the past 25 years has broadened, biomedical equipment inspection, electrical safety testing, and repairs still represent a substantial portion of most program efforts. Today, clinical engineering program services may include the following:

Equipment management services

- Inventory management
- Risk analysis
- Evaluation of new devices and systems prior to acquisition
- Vendor management
- Compliance (e.g., government regulations, accrediting standards)
- Educational services (for equipment users and clinical engineering staff)
- Device tracking (hazards and recalls)
- Root-cause analysis of adverse outcomes, incident investigation, and reporting
- Quality assurance
- Evaluation of investigational devices, processes, and procedures
- Design, fabrication, and modification of new or existing devices

Technical services

- Inspection and testing (functional, safety, performance)
- Calibration
- Preventive maintenance
- Corrective maintenance (i.e., repair)

Other than a broadening of the services offered, clinical engineering has not significantly changed. Given the technological, economic, cultural, and regulatory dynamics at work in the health care industry now, clinical engineering will be transformed before 2010. The nature and success of that transformation depends on the action that we take now as clinical engineers.

Take Action Now!

"If you want to prosper on the other side of a strategic inflection point, you must take action before you get there." —Andrew S. Grove, Intel chairman and cofounder

While still being mindful of our current business, we must lay the foundation for the future now. We cannot wait for events to overtake us, or we will risk irrelevance.

Clinical engineering must . . .

Adopt a Systems and Process Approach

Clinical engineering services traditionally have been oriented toward the management of discrete devices (i.e., equipment management). Systems and processes (i.e., technology management) were managed only marginally, when they were managed at all. Consideration of systems and processes requires looking at the big picture; not focusing on discrete devices but understanding ways in which individual devices must interconnect to accomplish a technical process. Clinical engineering must become more systems- and process-oriented. Increasingly, biomedical devices are becoming part of integrated technology systems. Technology will significantly contribute to quality of care, patient safety, patient outcomes, health-data integrity, and availability issues. These issues involve processes and require a systems approach in their management.

Add Basic Information Technology and Telecommunications Skills

For years, the trend has been for biomedical devices and systems to process increasing amounts of data and for these systems to be networked together to share these data. Today, "microprocessor," "RAM," "firmware," "software," "I/O port," and "Ethernet" are terms equally applicable to biomedical and IT systems. This confluence of biomedical, IT, and telecommunications technologies will continue in health care. IT and telecommunication technologies will supply the backbone along which integrated biomedical systems will operate. Clinical engineering must develop basic proficiencies in IT and telecommunications. To ensure support and coverage of these merging technologies, clinical engineering also must be prepared to integrate its services at an appropriate level with those of IT and telecommunications.

Monitor Technological, Regulatory, Economic and Other Developments

Clinical engineering must monitor the developments that are likely to impact the value of its contribution to the organization. Clinical engineering services should be structured to take these developments into consideration and to provide the maximum value. Clinical engineering should become proficient at new key technologies and be prepared to address new regulatory pressures and to account for economic issues in its technology planning.

Become Conversant with the "Business" of Technology

Clinical engineering must acquire expertise in the economic nuances pertaining to the adoption and use of technology, including cost/benefit analyses, return on investment

(ROI) analyses, and life-cycle-cost analyses. These considerations typically are the primary support for technology-related decisions made by health care executives. Clinical engineering must be prepared to supply these decision-makers with this information.

Plan for the Integration of Existing and New Medical Technologies

"Legacy" (i.e., existing and new) technologies will be integrated. Clinical engineering must anticipate the need for integration, understand the implications, and possess the necessary skills to manage the integration process successfully.

Develop Systems and Infrastructure to Support Technology in nontraditional Venues

Health care will be delivered increasingly outside of traditional venues (e.g., hospitals and clinics). Clinical engineering must be prepared to incorporate and support medical technology in non-traditional locations (e.g., patients' homes, assisted-living facilities, offices, schools, and public areas) by developing the necessary systems and infrastructure.

Closely Examine Existing Clinical Engineering Services and Practices

Clinical engineering must closely examine its existing services and practices to determine those that are necessary for the future, and those that should be discarded. Clinical engineering cannot afford to expend resources or to continue providing services for which there is little or no demonstrable benefit.

Incorporate Continuing Education

The pace of the health care technology revolution is quickening. Clinical engineering's only hope of making a contribution to the successful adoption of new technologies is to embrace a regimen of continuing education. Such education should include programs offered by universities, professional peer organizations, trade groups, and manufacturers. This education also should include regular literature research to identify current developments in technology and issues related to its adoption.

Build Relationships with Other Stakeholders

Teamwork is critical if the health care industry is to any hope of effectively addressing the technological, economic, regulatory, and social issues that it must address in the coming years. Clinical engineering should identify stakeholders in the technology-implementation process and should work to establish effective relationships with these key individuals and groups.

Develop a Plan to Transition from Existing to Future Services

Clinical engineering must develop and begin implementing a plan to transition from existing to future services. The plan must provide for acquisition of necessary skills and resources, education of clients as well as staff, and schedules to ensure a smooth transition.

Formulate a Vision for Clinical Engineering Within the Organization

Clinical engineering must develop and articulate a clear vision that is closely aligned with the vision and mission of the organization(s) served but also ensures that the vision promotes quality, service, and innovation.

Future Scope of Clinical Engineering Services

Education and experience typically endow the clinical engineer with a fundamental understanding not only of relevant technologies but also of the physiological systems on which that technology is applied, of the health care environment in which the technology is used, and of the regulatory framework in which the technology exists. Clinical engineers can be expected to develop organizational, project management, strategic planning, and investigative skills to ensure constant availability of safe and effective health care technology.

Given the forces for change and the clinical engineer's inherent and unique aptitudes, clinical engineering's future services are likely to include management consulting services, support services, and technical services.

Management and Consulting Services

Inventory and Asset Management

To remain viable, any business must effectively manage its assets. An accurate inventory is a fundamental component of any effective asset management program. Clinical engineering has assumed primary responsibility for maintaining the detailed inventory information on medical devices and systems, and it should continue to do so. The basic inventory information includes quantity, type, owner, acquisition/warranty dates, and monetary value of medical devices and systems. Additionally, clinical engineering must regularly assess and update a broad range of information on these devices and systems, including the following information:

- Current location
- Associated devices and systems (i.e., a record of interconnections to other devices and systems)
- Current physical and operating condition
- Degree of obsolescence

- Operating and service requirements and responsibilities
- Operating and service history
- Safety risk to patients and staff associated with device or system misapplication, failure, or lack of availability
- Financial risk to organization in case of device/system failure (i.e., is device or system mission critical?)
- History of recalls and reported hazards

Once collected, clinical engineering should use the above asset information to do the following:

- Provide a document trail regarding the condition, use, and servicing of devices and systems.
- Prepare capital budgets and schedule upgrades or replacements of worn or obsolete devices and systems.
- Encourage the standardization of devices and systems.
- Facilitate integration between other devices and systems.
- Plan the type, schedule and frequency, and source of service (i.e., calibration, inspection, and pm).
- Prepare service and operating budgets for medical devices and systems.
- Conduct risk analyses and facilitate risk mediation efforts (including disaster planning).
- Analyze performance, integrity, and reliability of devices and systems.
- Analyze quality and effectiveness of technical services provided to devices and systems.
- Establish the real financial value for the organization's medical technology assets.

Strategic Planning

The evolution of health care technology is rapidly accelerating on a number of fronts. As this increasingly wide array of technology becomes available, it has the potential to impact health care delivery positively by improving quality, safety, and availability, while reducing costs. However, these positive effects can only be realized through careful planning, adoption, and integration of appropriate technologies into the health care delivery process. Clinical engineering is uniquely suited to contribute to the strategic planning process that is due. Clinical engineers must be prepared to use their unique abilities to do the following:

- Continually work to sharpen their awareness of existing and newly available technologies
- Evaluate the technical strengths and limitations in the context of the intended applications
- Apply their knowledge of the environment where the devices or systems are to be used, to the appropriate selection and configuration of devices and systems
- Plan for installation, integration with other systems, training, and on-going service
- Contribute to cost-benefit and life cycle cost analyses

Quality & Safety

In recent years, quality and safety have become, and are likely to continue to be, a major concern of the U.S. health care industry. Technology has the potential to contribute to quality and safety, but it can be detrimental if not properly managed. To ensure that technology's impact is positive, clinical engineering must:

- Adopt a quality-management system (e.g., ISO 9000, Six Sigma, or Malcolm Baldrige) that will facilitate identifying:
 - Performance criteria for technical systems and processes
 - Target goals and objectives (benchmarks) associated with use of technology
 - Methods for achieving these goals and objectives
 - Techniques for measuring progress toward goals and objectives
 - A process for analyzing and improving the effectiveness of methods of achieving goals and objectives
- Implement a risk-management program including:
 - An assessment program that identifies risks by evaluating the implications of failure of technical systems and their related processes on patient health, patient/staff safety, and the financial well-being of the organization
 - A mitigation program that prioritizes identified risks and provides methods for reducing them to an acceptable level
- Provide root-cause analysis, investigation, and reporting support when technology and technical processes are involved in adverse outcomes or incidents
 - Identify contributing causes
 - Propose recommendations to prevent reoccurrence

Compliance

Government and industry produce an ever-changing array of regulations and standards that impact health care technology. A clinical engineer's role includes ensuring compliance with the relevant government, accreditation, and industry standards and initiatives (e.g., FDA, SMDA, HIPAA, JCAHO, IOM, and IHE). This requires them to understand existing laws, standards, codes, and practices, and to remain current on changes. Clinical engineering also must take steps to ensure that technical systems and processes are used and maintained in a manner that ensures compliance with all relevant regulations and standards.

Vendor Management

Vendors include medical-technology manufacturers, distributors, and independent service organizations. Because health care organizations necessarily work with vendors to obtain medical technology and technical services, clinical engineering needs to ensure that the working relationship is an effective one for all parties. Clinical engineering should serve as technical liaison, ensuring that vendors have all of the information and access that is necessary for them to deliver appropriate technology and services. Clinical engineering also should:

- Evaluate vendors and their products and services, recommending those that best meet the needs and standards of the organization.
- Ensure inclusion of necessary terms and conditions in agreements with the vendor and regularly ensure vendor compliance with those terms and conditions.
- Ensure that the vendor makes available any information, documentation, software, specialized tools, and education that is necessary for operating or servicing technology.
- Verify integrity of technology supplied.
- Monitor vendor quality and the integrity of services delivered.

Support Services

Education

Clinical engineering's role in technical education should continue to change. It is important to train users in the proper operation of technical systems. Their expertise in technology and understanding of applications make clinical engineers uniquely well-suited to complement application training with education of users on the effective use and basic troubleshooting of devices and systems.

Help Desk

Clinical engineering should adopt the "help desk" concept. The concept of a help desk comes from the information technology industry. The proliferation of business computers onto the desks of non-IT personnel resulted in the need for a readily identifiable and available source of technical expertise (i.e., the help desk). When computer users experienced inevitable computer problems, they could telephone a software or hardware consultant at a help desk who could talk the users through a solution, thereby solving the problem more quickly and less expensively than could be done by an on-site visit from IT personnel. The use of remote access and remote control software in recent years has further enhanced the ability of the help desk personnel to assist, troubleshoot, and solve problems remotely. If clinical engineering were to adopt the help desk approach, it could complement existing services by providing some operating and basic technical support for system and device users (e.g., clinicians and patients). As increasingly more medical systems are connected via telecommunications, networks and the Internet, the help desk can perform remote troubleshooting, diagnostics, and system upgrades. Senior technical personnel on such a help desk also would be available to support less-experienced technical staff at remote locations.

Technical Services

Installation and Integration

Installation of new technology today frequently requires software/hardware configuration and integration into existing systems. The level of integration of medical systems will increase substantially in the future. Clinical engineering's expertise in a wide variety of technical systems and applications makes it well suited to provide guidance and technical assistance in installation and integration services.

Upgrades

System upgrades will become more commonplace as advances occur in medical hardware and software. Technology owners will attempt to curb costs by staggering upgrades of components and software, rather than upgrading an entire system at once. Clinical engineering must be prepared to provide advice and assistance in this upgrade process.

Testing, Inspection and Preventive Maintenance

The roles of testing, inspection, and preventive maintenance (PM) will significantly decrease. Devices and systems will continue to require testing and inspection upon installation. However, routine testing and inspection on devices and systems where it has been demonstrated that the test/inspection results never vary is questionable, both in value and in the use of limited resources. Medical technology has become sufficiently reliable that visual inspections, operational checks, and monitoring of self-diagnostics by technical staff and users will largely replace traditional forms of inspection, testing, and PMs.

Repair

Clinical engineering will continue to offer repair services for medical technology, but the amount and nature of repair services certainly will change. Repair services will occupy fewer clinical engineering resources as the technology continues to become more reliable and to incorporate self-diagnostics. Repairs also will focus increasingly on troubleshooting and solving problems associated with systems of interconnected devices.

Conclusion

Clinical engineering is at a strategic inflection point. Technical, economic, regulatory and cultural dynamics are at work shaping the future of health care delivery. As the nature of health care delivery is transformed by these forces, the types and mix of technology management and support services needed by the industry are changing significantly. Clinical engineering has a relatively short opportunity to adopt a service model that will meet these changing needs. Delay or failure to adopt an effective service model as we pass through the inflection point will result in a diminished role for clinical engineering in

health care technology management as other technical professionals move in to fill the need. The question is: Will clinical engineering rise to the challenge?

Virtual Instrumentation—Applications to Health Care

Eric Rosow

Director of Biomedical Engineering
Hartford Hospital
Hartford, CT

Successful organizations have the ability to measure and to act on key indicators and events in real time. By leveraging the power of virtual instrumentation and open-architecture standards, multidimensional executive dashboards can empower health care organizations to make better and faster data driven decisions. This chapter will highlight ways in which user-defined virtual instruments and dashboards can connect to hospital information systems (e.g., ADT systems and patient monitoring networks) and utilize statistical process control (SPC) to “visualize” information and to make timely, data driven decisions. The case studies described will illustrate enterprise-wide solutions for:

- Bed management and census control
- Operational management, data mining and business intelligence applications
- Clinical applications

Background

Virtual instrumentation (VI) allows organizations to effectively harness the power of the PC, to access, analyze, and share information throughout the organization. With vast amounts of data available from increasingly sophisticated enterprise-level data sources, potentially useful information is often left hidden, due to a lack of useful tools. Virtual instruments can employ a wide array of technologies, such as multidimensional analyses and statistical process control (SPC) tools, to detect patterns, trends, causalities, and discontinuities to derive knowledge and to make informed decisions.

Today's enterprises create vast amounts of raw data, and recent advances in storage technology; coupled with the desire to use these data competitively, has caused a data glut in many organizations. The health care industry, in particular, generates a tremendous amount of data. Tools such as databases and spreadsheets certainly help to manage and analyze these data, however databases, while ideal for extracting data, are generally not suited for graphing and analysis. Spreadsheets, on the other hand, are ideal for analyzing and graphing data, but this process can be cumbersome when working with multiple data files. Virtual instruments empower the user to leverage the best of both worlds by creating a suite of user-defined applications that allow the end-user to convert vast amounts of data into information that is ultimately transformed into knowledge to enable better, faster decision making.

Benefits of User-Defined Virtual Instruments

The benefits of virtual instrumentation are increased performance and reduced costs. Because the user controls the technology through software, the flexibility of virtual instrumentation is unmatched by traditional instrumentation. The modular, hierarchical programming environment of virtual instrumentation is inherently reusable and reconfigurable.

In effect, virtual instrumentation allows the user to “morph,” (i.e., replicate and/or customize) the functionality of traditional “vendor-defined” instruments (such as the oscilloscope shown in Figure 136-1) into virtual “user-defined” instruments on a standard computer or personal digital assistant (PDA).

Virtual instrumentation applications have encompassed nearly every industry, including the telecommunications, automotive, semiconductor and biomedical industries. In the

Figure 136-1 Virtual instrumentation: Replicating and enhancing traditional “vendor-defined” instruments with virtual “user-defined” instruments. (Courtesy of National Instruments.)

fields of health care and biomedical engineering, virtual instrumentation has empowered developers and end-users to conceive of, develop, and implement a wide variety of research-based biomedical applications and executive information tools. These applications fall into several categories, including process improvement, decision support, and clinical research. The following case studies are intended to illustrate the myriad of applications that are possible with this powerful technology.

The Lab VIEW Development Environment

For many of its VI solutions discussed in this chapter, an application development environment (ADE) called LabVIEW has been used. LabVIEW was created by National Instruments (Austin, TX). It is an off-the-shelf graphical development environment designed specifically for developing integrated measurement and automation systems. Developers assemble user interfaces and high-level functions for data acquisition and control, signal processing and analysis, and visualization, in the same way that flowcharts are constructed. With the modularity and hierarchical structure of LabVIEW, users can quickly and easily prototype, design, deploy, and modify systems. The LabVIEW ADE is compiled for maximum execution performance, contains hundreds of advanced analysis routines, and allows developers to quickly design and build advanced applications.

This chapter presents several “real-world” virtual instrument applications and tools that have been developed to meet the specific needs of health care organizations. Particular attention is placed on the use of quality control and “performance indicators,” which provide the ability to trend and forecast various metrics and improve processes. The use of statistical process control (SPC) and modeling within virtual instruments is demonstrated. Finally, several clinical research applications of virtual instrumentation are described.

Case Study #1: A Real-Time Bed-Management and Census-Control Dashboard

The Problem

Most health care institutions today manage patient flow via paper, whiteboards, and phone calls. As a result, hospitals often lack precise and timely information to match bed availability with patients’ clinical needs. This causes inefficient use of beds, resources, and provider time, which leads ultimately to reduced throughput; emergency department (ED) overcrowding; lost admissions; operating room (OR) delays; unhappy physicians, staff, and patients; decreased revenue; and higher expenses.

Industry Trends

Concerns over patient access to hospital care are quickly becoming the largest, most urgent health care issue on the public’s agenda. Many hospitals are now struggling to cope with surprising increases in the numbers of patients. Nationwide, hospitals report unprecedented inpatient and outpatient volumes, while average occupancy levels approaching 100% are not uncommon. These problems are compounded by two nationwide trends in hospitals: (1) increases in the numbers of patients; and (2) decreases in the numbers of beds.

Some hospitals are being forced to turn away ambulances and to cancel or delay elective surgeries because of a shortage of hospital beds. At other hospitals, ED patients wait hours, or even days, for rooms. Administration has no information to be able to match proactively the demand for patients with the appropriate level of nurse staffing. In addition, aging baby boomers are more likely to experience serious illness or injury, and medical advances are helping doctors to treat conditions that patients simply might have accepted in the past. There is an overall staff shortage of hospital workers, especially among nurses. With no sign of slowdown in these trends, these problems in hospital care appear set to escalate for the foreseeable future (AHA, 2001).

The Solution

The Bed Management Dashboard (BMD) is a real-time process improvement and decision support product used by hospital administrators, clinicians, and managers on a constant basis. It is an enterprise-wide system that directly and indirectly interacts with all departments throughout the continuum of care (see Figure 136-2).

Process Improvement

Process improvement is an outcome and benefit of a centralized Bed Management Process that maintains clinical input and incorporates technological support. The BMD streamlines the process of admitting, transferring, and discharging patients by:

- Optimizing patient placement processes
- Increasing staff efficiency (e.g., by reducing administrative expenses by eliminating paperwork and phone volume)
- Improving utilization of beds (e.g., by reducing inappropriate usage of inpatient beds without payer authorization, 23+ hour observation of outpatients by automatic alerts)
- Optimizing utilization of material resources (e.g., monitored beds and negative pressure rooms)
- Managing patient flow in the event of Admissions/Discharge/Transfer (ADT) system or network failure (disaster recovery)
- Enabling real-time and predictive capacity management
- Providing clinical attributes to supplement ADT data (e.g., telemetry and near nursing stations)

This results in:

- Reduced emergency room overcrowding
- Reduced operating room delays
- Increased physician and staff satisfaction
- Improved patient flow
- Time savings
- Better treatment of patients and improved customer satisfaction
- Reduced diversions and lost admissions
- Increased revenues and decreased expenses
- Reduced staff

Decision Support

The BMD allows administrators, clinicians, and managers to easily access, analyze, and display real-time patient and bed-availability information. It provides:

- On-demand historical, real-time, and predictive reports
- Alerts, warnings, and recommendations
- The ability to share information throughout the enterprise
- Provides point-in-time predicted bed availability
- The ability for decision-makers to move easily from “big-picture” analyses to transaction details

This results in:

- Timely data driven decisions
- Improved decisions regarding staffing levels
- Reduce reliance on third-party staffing companies to supplement in-house staff
- Improved crisis management during rapidly fluctuating census levels
- The improved ability to negotiate contracts with payers

The BMD has been running at Hartford Hospital since April 2001. It has over 900 trained users, and it can be accessed on the more than 2500 work stations throughout the organization. The system is interfaced to the Hospital’s Admission/Discharge/Transfer (ADT) Information System (Siemens/SMS), pagers, phones, and e-mail.

An Air Traffic Control Tower for Beds

In many ways, the BMD is similar to an air traffic control tower. Like a real air traffic control tower, this application is real-time and mission-critical. It must handle scheduled and

Figure 136-2 The Bed Management Dashboard across the Enterprise: The BMD interacts with all departments throughout the continuum of care (e.g., admitting, ED, OR, ICU, and administration).

emergency events. The system assists with the clinical and business decision processes that occur when a patient needs to be assigned to a specific bed location. Collectively, this system provides organizations with an array of enabling technologies to:

- Schedule/Reserve/Request patient bed assignments
- Assign and transfer patients from the emergency department and/or other clinical areas such as intensive care units, medical/surgical units, operating rooms, and post-anesthesia care units
- Reduce and eliminate dependency on phone calls to communicate patient and bed requirements
- Reduce and eliminate paper processes to manage varying census levels
- Apply statistical process control (SPC) and “Six Sigma” methodologies to manage occupancy and patient diversion
- Provide administrators, managers, and caregivers with accurate and on-demand reports and automatic alerts via pagers, e-mail, phone, and intelligent-software agents

How It Works

The Bed Management Dashboard is accessible via a web browser or via a client application. The supporting architecture of the BMD system is a standard N-tier server-based system, which, depending on the end users’ needs, consists of one or more of the following: A web server, an application server, a database server, and an ADT interface server.

Key information from the hospital’s ADT system is automatically fed to the BMD via a Health Level Seven (HL7) data stream. The system has been designed to accept inputs from patient monitoring and nurse-call networks. Figure 136-3 illustrates the flow of information from the ADT system to the user’s desktop. The system typically receives up to 12,000 transaction messages per day, which are parsed into appropriate data elements by an HL7 parser and are stored on a database server.

The log-in authentication module accesses a hospital’s central user log-in repository to validate the user’s log-in information. This module enables single-user sign-on (SSO) capability by providing a user with the same username and password used by the other applications that authenticate to the central user log-in repository.

The integrated data-mining and report module consists of a number of standard reports that take advantage of the data warehouse nature of the BMD. These reports include, but are not limited to, a historical census report, a real-time census report, a bed manager report, a physician discharge report, and a discharge compliance report. In addition, access to the data by industry standard report writers, such as Crystal Reports and Access, give technical users the ability to create complicated or special reports as desired. For example, the BMD offers extensive ad hoc reporting capabilities ranging from length of stay (LOS) and “Care Day” metrics to asset management analyses (on beds and patient-monitor utilization), to biosurveillance reports that have been requested by state and federal organizations such as the Department of Public Health and the Centers for Disease Control and Prevention.

The utility and configuration module gives system operators the ability to administer BMD users (e.g., to add new users and to modify new or existing user security settings); to administer service, unit, rooms and beds (e.g., to add or modify clinical services, units, rooms, and beds, and their inter-relationships); to define automated alert thresholds; and to configure unit floor plan diagrams.

The embedded back-up utility module consists of a local version of the bed-management database that is constantly updated. Access to this database gives users a self-contained and mobile version of the system that can be used in the event of catastrophic

failure of the system hardware or network hardware or in the event of a crisis that removes the users from direct access to the hospital network.

One of the most important features of the BMD is that it reformats information from the ADT system and presents it to the clinical user in a more “user-friendly” and process-oriented manner. Dynamic and interactive graphical presentations of data are used extensively. Figure 136-4 illustrates the way in which all of the patients from a given admitting source, such as the emergency department, can be displayed and selected from a dynamically sortable “smart table.”

Hospital beds are classified as having predefined “attributes,” such as being “monitored” or being assigned to the “surgery” service. The needs of patients are similarly described with attributes, such as “monitor required” or “scheduled for surgery.” As illustrated in Figure 136-5, the BMD helps to find those available beds in the hospital that meet the specific needs of a patient by guiding the clinical staff through a set of process screens that perform the match.

Decisions for patient placement can be centralized or decentralized. The dashboard allows proper communication between the appropriate parties. Status of decisions is automatically tracked, and a monitoring process can detect and notify key stakeholders of any process delays. Admitting or emergency departments can be automatically notified of decisions, if appropriate. Reporting of information is provided by online screen views of data tailored to the needs of a particular class of system user. Unit personnel can view either detailed information or summary roll-ups about their patients. Figure 136-6 illustrates ways in which patient information can be viewed in a dynamic and interactive floor-plan mode.

Administrators and program directors can view data over a wider scope that encompasses multiple units, services, or physicians. An example of a summary report is shown in Figure 136-7.

A key feature of this system is its use of “Intelligent Agents.” These online agents, as shown in Figure 136-8, are constantly monitoring and analyzing patient and census information, and they have the ability to detect key system situations, such as high census in a unit (i.e., no available beds), excessive ED placement time for a particular patient, or delays in responses to placement requests.

The BMD allows users to run real-time queries and reports on current and future hospital census (Figure 136-9). These reports are stratified by inpatients, outpatients, acute units, non-acute units, and/or services (“collaborative management teams”). In addition, budgeted discharge, length-of-stay, and care day statistics, along with average and peak occupancy indicators, are also profiled.

Patient Confidentiality

A full-security system is embedded within the dashboard to audit user access and to assign users to definable system roles. These roles are restricted to specified processes and are prohibited from viewing or changing certain data. The system is designed to be fully compliant with the evolving Health Insurance Portability and Accountability Act (HIPAA) regulations.

The BMD at Hartford Hospital on September 11, 2001

The dashboard played a critical role at Hartford Hospital on that terrible day of September 11, 2001. When the news came in from New York (just 100 miles away) Hartford Hospital was told to expect hundreds of injured patients. At that time, the hospital had only seven open beds, two of which were ICU beds. The BMD played an important role with respect to providing real-time occupancy information, predictive capacity management, and biosurveillance reporting.

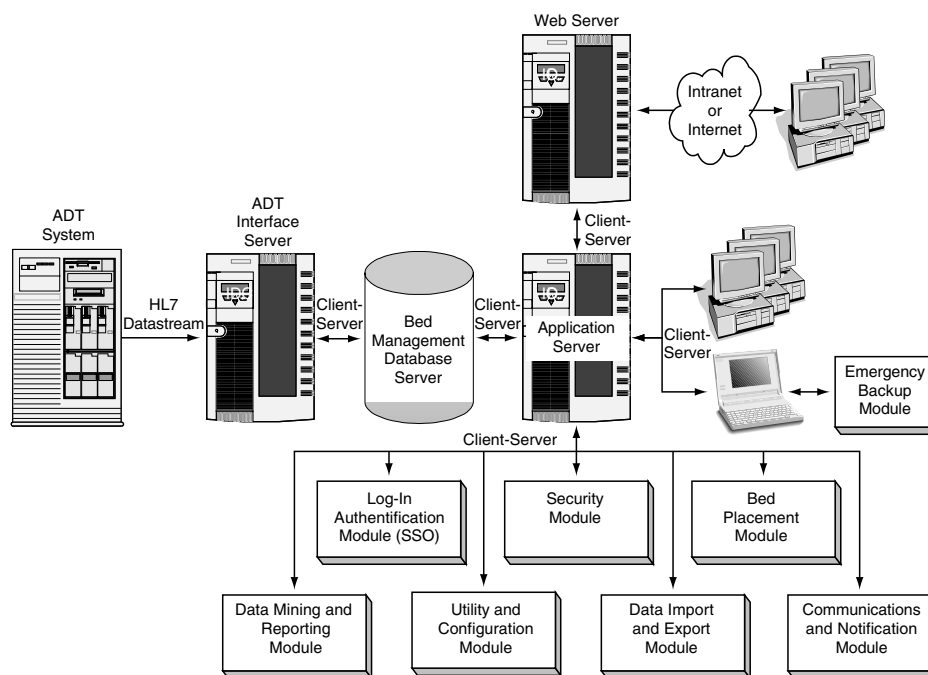

Figure 136-3 System diagram: The BMD consists of four major components: the ADT interface, the database server, an application server and a web server. The system has been designed to interface with any ADT system that provides an HL7 interface and utilizes TCP/IP as a communication protocol.

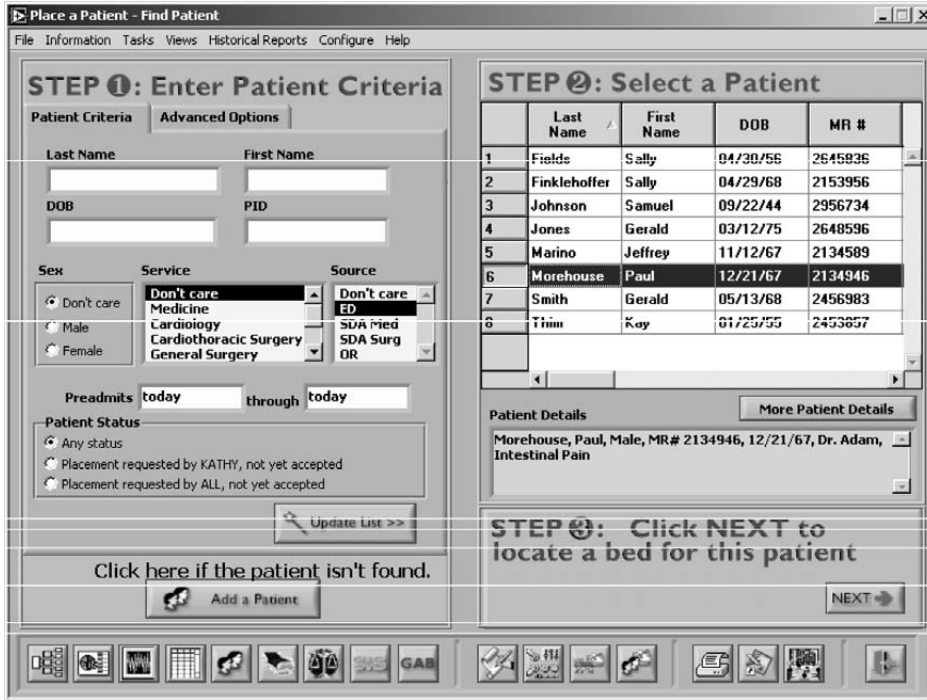

Figure 136-4 Find Patient: This screen is primarily used to request a bed for a patient. The user first enters various criteria to identify the patient. The system then displays all of the patients who meet the specified criteria. Finally, the user selects the patient in question and presses “NEXT” to move to another screen, where an available bed is located and requested.

Specifically, the dashboard helped in the following ways:

- It improved efficiency by eliminating the need for whiteboards and many phone calls
- It allowed for predictive occupancy reports to help free up 150 beds in a timely and orderly fashion
- It provided an efficient way to collect and report biosurveillance data that were required by the Connecticut Department of Public Health

The key factor in this success story was that the dashboard was directly linked to the hospital census database so that accurate data were constantly available to the command center. The dashboard displays were easily, rapidly, and repeatedly revised to facilitate iterative decision making.

Demonstrated Return on Investment (ROI)

Since its installation in April 2001, the system has more than paid for itself through achievement of the following indicators obtained from actual observations at Hartford Hospital.

- \$200,000 annual expense avoidance by reducing the number of Bed Manager FTEs needed
- A 50% decrease in the number of phone calls per bed assignment/patient placement
- A 75%–90% decrease in the overall time needed for the patient-placement process
- A 50% decrease in the number of paper forms used
- A 25% increase in throughput by alerting bed managers to discharges sooner of those that are reported to bed managers

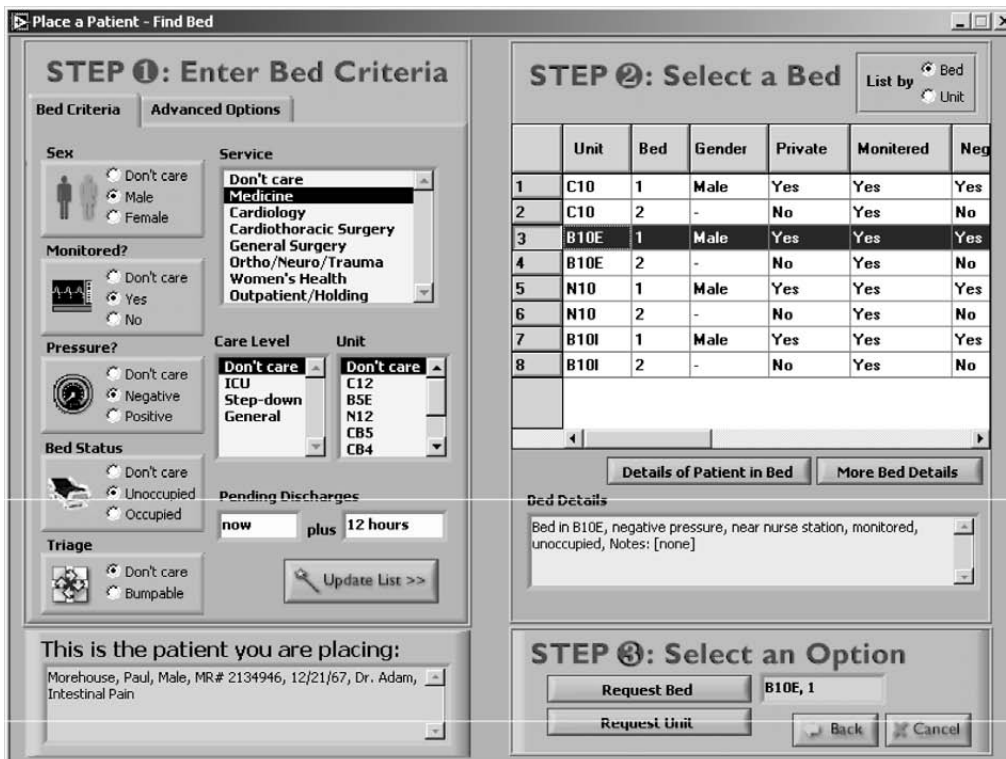

Figure 136-5 Find Bed: Once a patient has been selected, this “Bed Finder” screen is used to locate a specific bed or unit for the patient. The user first enters various criteria about the type of bed that is needed (e.g., patient gender, monitor required, and negative-pressure room required). The system then displays all of the available beds that meet the specified criteria. Finally, the user selects a particular bed or unit for the previously specified patient.

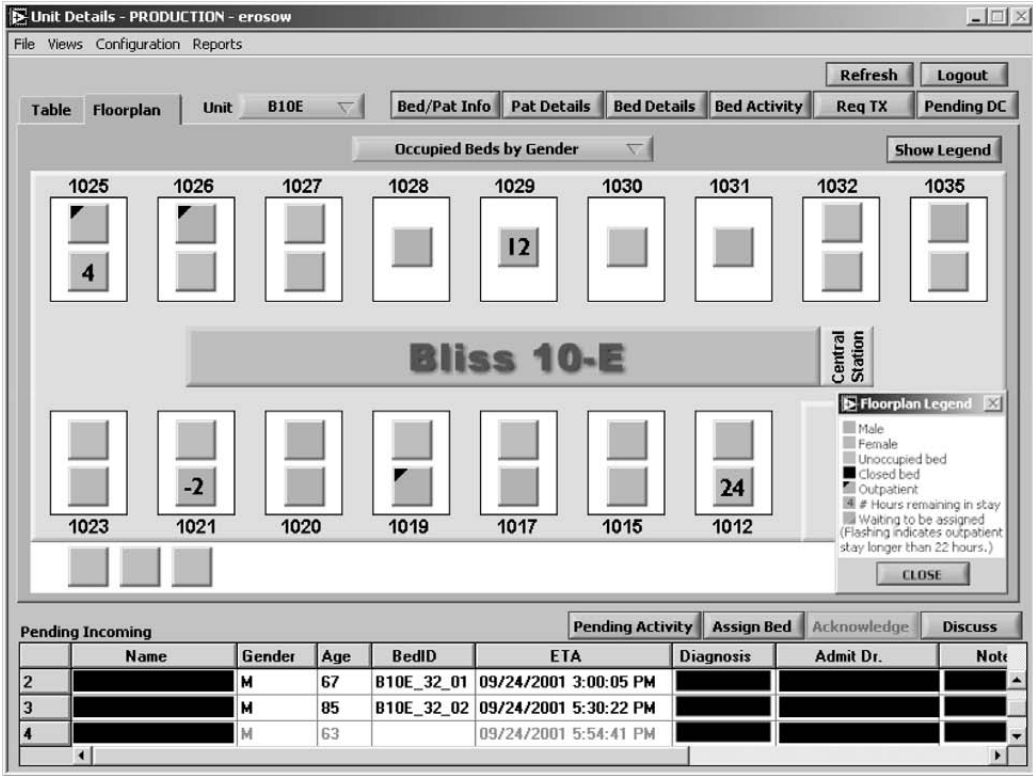

Figure 136-6 Unit Details (floorplan view): This screen provides a graphical view of an intensive care unit. Each bed is presented as a square, using a simplified floor-plan view. Colors are used to indicate the selected attribute of the patient or bed. For example, the above screen indicates available beds in green, and occupied beds in red. The gray beds (which are flashing) are those with pending discharges, and the black bed is closed or inactive. Many other color-coded options are available via the pull-down selector. These include patient and bed attributes such as gender, monitored bed, negative-pressure room, and service (e.g., cardiology, surgery, and orthopedics).

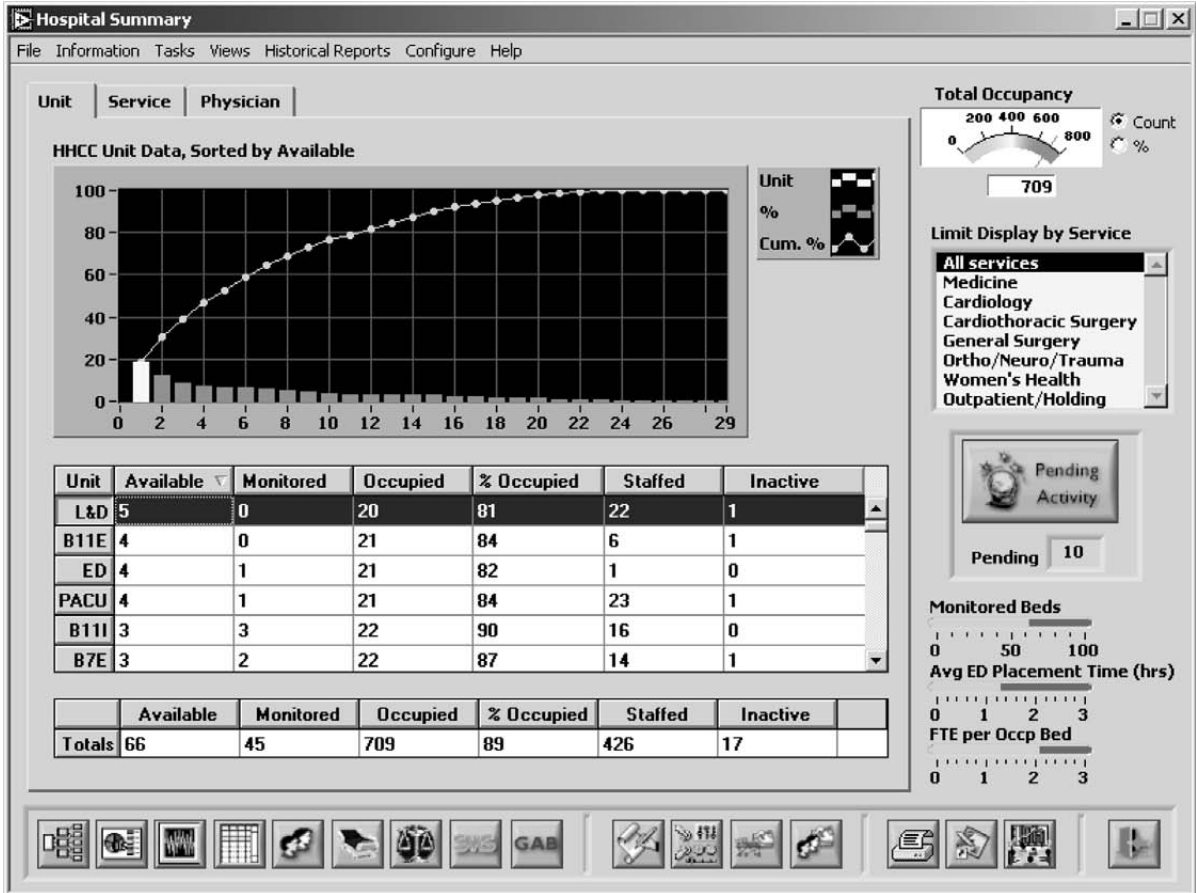

Figure 136-7 Hospital Summary: This screen is primarily used by administrators who need to see a global view of the hospital status. Table and Pareto charts profile the various units and the current status summaries of each unit. These patients also can be rolled up into services, or grouped by physician. In addition, patients can be aggregated in many other ways, such as time of admission, length of stay, and admitting diagnosis.

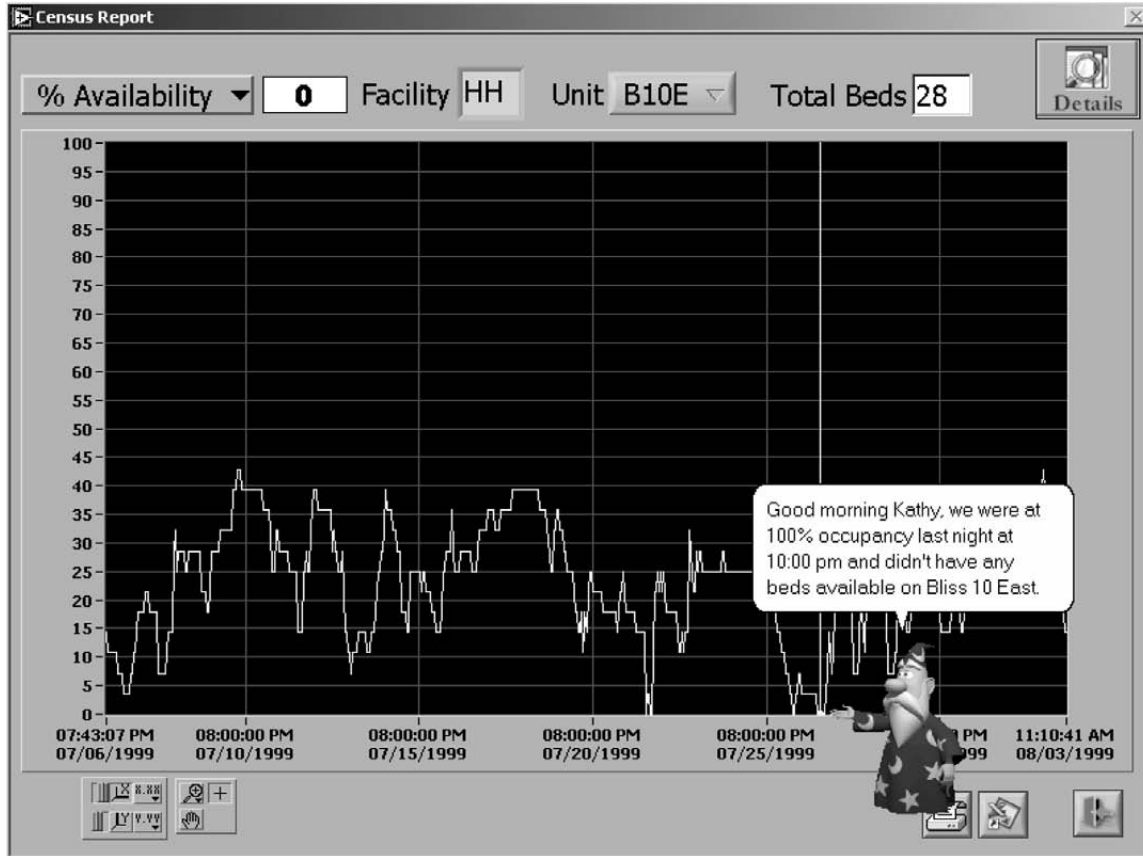

Figure 136-8 Intelligent Agents: The BMD can also employ online “intelligent agents” to provide assistance and to alert the user of important alarm conditions that otherwise might have gone unnoticed. Messages can be in the form of an on-screen agent (such as Merlin the Wizard) or via e-mail, pager, fax, and/or telephone.

Case Study #2: PIVIT™-Performance Indicator Virtual Instrument Toolkit

Most of the information management examples presented in the chapter are part of an application suite called PIVIT.™ The name is an acronym for “Performance Indicator Virtual Instrument Toolkit.” PIVIT is an easy-to-use data acquisition and analysis product. PIVIT was developed specifically in response to the wide array of information and analysis needs throughout the health care setting. Figure 136-10 illustrates the main menu of PIVIT.

PIVIT applies virtual instrument technology to assess, analyze, and forecast clinical, operational, and financial performance indicators. Some examples include applications that profile institutional indicators (e.g., patient days, discharges, percentage of occupancy, ALOS, revenues, and expenses), and departmental indicators (e.g., salary, non-salary, total expenses, expense per equivalent discharge, and DRGs). Other applications of PIVIT include 360-degree peer review, customer satisfaction profiling, and medical equipment risk assessment.

PIVIT can access data from multiple data sources. Virtually any parameter can be easily accessed and displayed from standard spreadsheet and database applications (e.g., Microsoft Access, Excel, Sybase, and Oracle), using Microsoft’s Open Database Connectivity (ODBC) technology. Furthermore, multiple parameters can be profiled and compared in real time to any other parameter via interactive polar plots and three-dimensional displays. In addition to real-time profiling, other analyses, such as statistical process control, can be employed to view large data sets in a graphical format. Statistical process control has been applied successfully for decades to help companies reduce variability in manufacturing processes. These SPC tools range from Pareto graphs to Run and Control charts. Although it will not be possible to describe all of these applications, several examples are provided below to illustrate the power of PIVIT.

Trending, Relationships, and Interactive Alarms

Figure 136-11 illustrates a virtual instrument that interactively accesses institutional and department-specific indicators and profiles them for comparison. Data sets can be acquired directly from standard spreadsheet and database applications (e.g., Microsoft Access, Excel, Sybase, and Oracle). This capability has proved to be quite valuable with respect to quickly accessing and viewing large sets of data. Typically, multiple data sets contained within a spreadsheet or database had to be selected, and then a new chart of these data had to be created. Using PIVIT, the user simply selects the desired parameter from any one of the pull-down menus, and this data set is instantly graphed and compared to any other data set.

Interactive “threshold cursors” dynamically highlight when a parameter is over and/or under a specific target. Displayed parameters can also be ratios of any measured value (e.g., “Expense per Equivalent Discharge” or “Revenue to Expense Ratio”). The indicator color will change, based on the degree to which the data value exceeds the threshold value (e.g., from green to yellow to red). If multiple thresholds are exceeded, then the entire background of the screen (normally gray) will change to red, to alert the user of an extreme condition.

Finally, multimedia has been employed by PIVIT to alert designated personnel an audio message from the personal computer or by sending an automated message via e-mail, fax, pager, or mobile phone.

PIVIT also is able to profile historical trends and to project future values. Forecasts can be based on user-defined history (e.g., “Months for Regression”), the type of regression (linear, exponential, or polynomial), the number of days, months, or years to forecast, and whether any offset should be applied to the forecast. These features allow the user to create an unlimited number of “what-if” scenarios and to allow only the desired range of data to be applied to a forecast. In addition to the graphical display of data values, historical and projected tables are also provided. These embedded tables look and function like a standard spreadsheet.

Data Modeling

Figure 136-12 illustrates another way in which virtual instrumentation can be applied to financial modeling and forecasting. This example graphically profiles the annual morbidity, mortality, and cost associated with falls within the state of Connecticut. Such an instrument has proved to be an extremely effective modeling tool due to its ability to highlight relationships and assumptions interactively, and to project the cost and/or savings of employing educational and other interventional programs.

Virtual instruments such as these are not only useful with respect to modeling and forecasting but, perhaps more importantly, they become a “knowledge base” in which interventions and the efficacy of these interventions can be statistically proved.

The example program in Figure 136-13 shows ways in which virtual instrumentation can employ standard Microsoft Windows® technology (in this case, Dynamic Data Exchange (DDE)) to transfer data to commonly used software applications such as Microsoft Access® or Microsoft Excel.® It is interesting to note that in this example, the virtual instrument can measure and graph multiple signals while sending these data to another application that could reside on the network or across the Internet.

In addition to utilizing DDE, virtual instrumentation can use other protocols for inter-application communication. These range from simple serial communication to TCP/IP and ActiveX.

Figure 136-14 illustrates the Communications Center. This application shows various methods by which the user can communicate information throughout an organization. The Communications Center can be used to simply create and print a report, or it can be used to send e-mail, faxes, or messages to a pager, or even to leave voicemail messages. This is a powerful feature in that information can be distributed easily and efficiently to individuals and groups in real time.

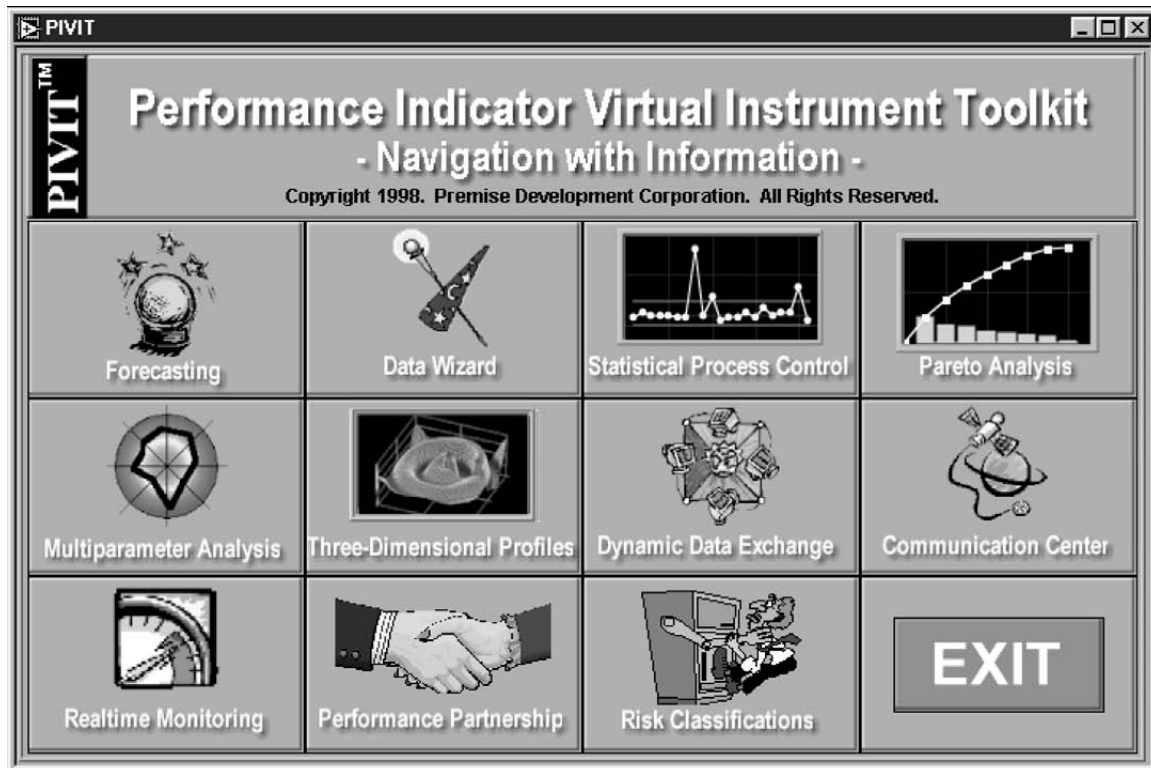

Figure 136-10 The Performance Indicator Virtual Instrument Toolkit (PIVIT™) Main Menu.

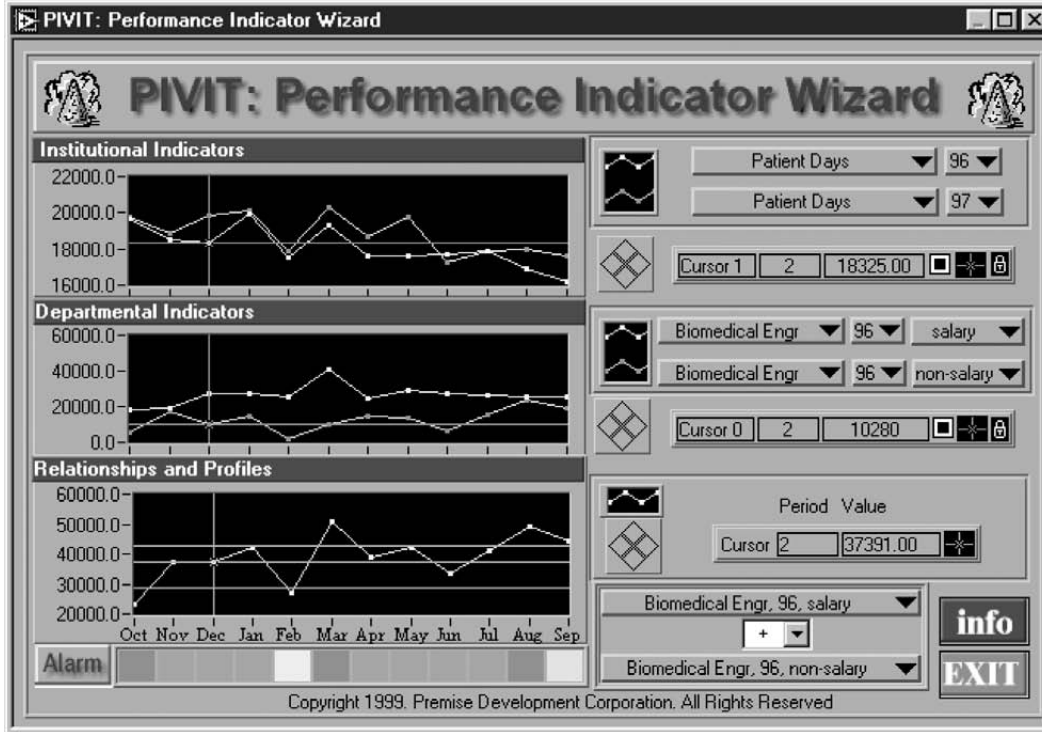

Figure 136-11 PIVIT—Performance Indicator Wizard Display Institutional and Departmental Indicators.

Additionally, Microsoft Agent technology can be used to pop up an animated help tool (“Merlin the Wizard”). Merlin then can be used to communicate a message or to indicate an alarm condition, or it can be used to help the user to solve a problem or to point out a discrepancy that otherwise might have gone unnoticed. Agents employ a “text-to-speech” algorithm to actually “speak” an analysis or alarm directly to the user or the recipient of the message. In this way, on-line help and user support can be provided in multiple languages.

In addition to real-time profiling of various parameters, more advanced analyses, such as statistical process control (SPC) can be employed to view large data sets in a graphical format.

SPC has enormous applications throughout health care. Such perceived applications were significant drivers to embed SPC tools into PIVIT’s suite of virtual instruments. For example, Figure 136-15 is an example of a way in which Pareto analysis can be applied to a sample trauma database of over 12,000 records. The Pareto chart could show frequency or

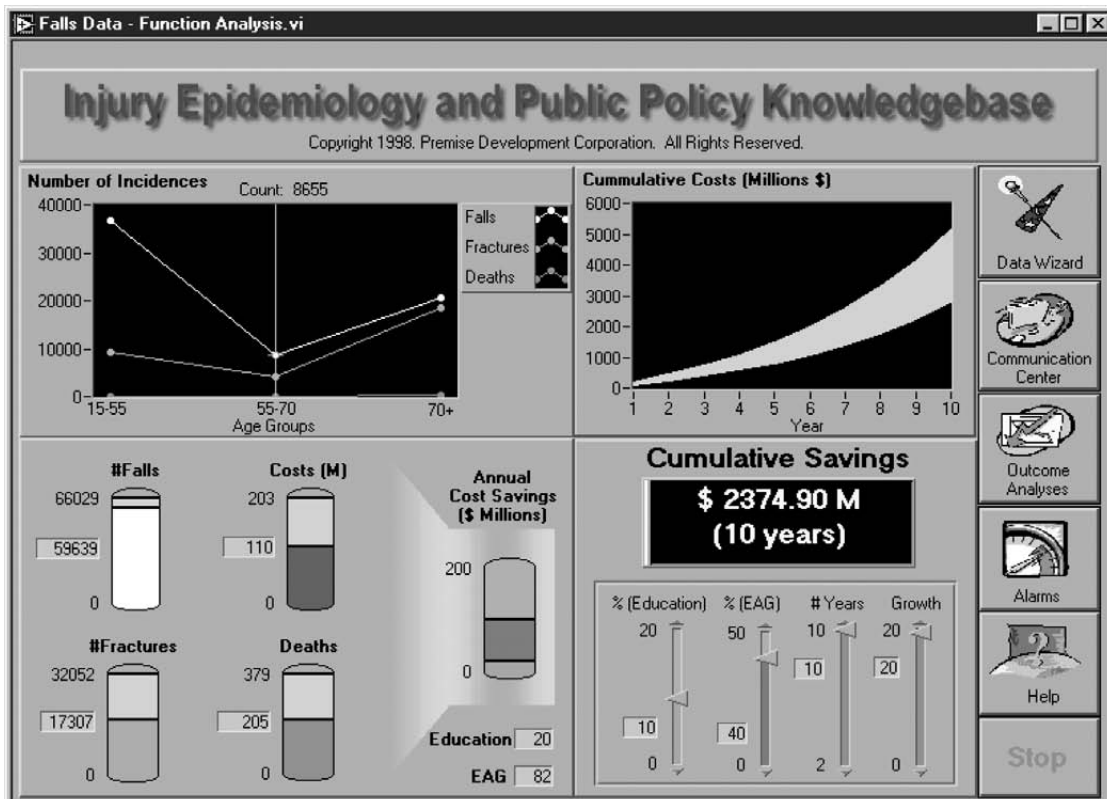

Figure 136-12 Injury Epidemiology and Public Policy Knowledgebase.

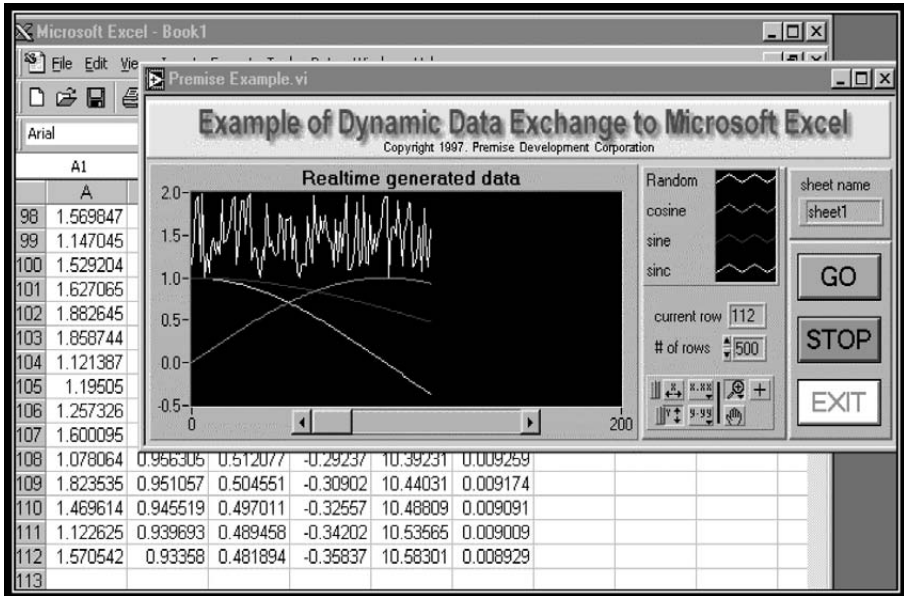

Figure 136-13 Example of Dynamic Data Exchange (DDE) for Interapplication Communication.

percentage, depending on front-panel selection, and the user can select from a variety of different parameters by clicking on the “pull-down” menu. This menu can be configured to automatically display each database field directly from the database. In this example, various database fields (e.g., DRG, Principal Diagnosis, Town, and Payer), can be selected for Pareto analysis. Other tools include run charts, control charts, and process capability distributions.

Medical Equipment Risk Criteria

Figure 136-17 illustrates a virtual instrument application that demonstrates the way that four “static” risk categories (and their corresponding values) are used to determine the inclusion of clinical equipment in the Medical Equipment Management Program at Hartford Hospital. Each risk category includes specific subcategories that are assigned points, which, when added together according to the formula listed below, yield a total score that will range from 4 to 25.

Considering these scores, the equipment is categorized into five priority levels (i.e., High, Medium, Low, Grey List, and Non-Inclusion into the Medical Equipment Management Program). The four static risk categories are Equipment Function (EF), Physical Risk (PR), Environmental Use Classification (EC), and Preventive Maintenance Requirements (MR).

Equipment Function (EF)

Stratifies the various functional categories (i.e., therapeutic, diagnostic, analytical and miscellaneous, of equipment). The specific rankings for this category are listed in Table 136-1.

Physical Risk (PR)

Lists the “worst-case scenario” of physical-risk potential to either the patient or the operator of the equipment.

Environmental Use Classification (EC)

Lists the primary equipment area in which the equipment is used.

Preventive Maintenance Requirements (MR)

Describes the level and frequency of required maintenance. The Aggregate Static Risk Score is calculated as follows:

Aggregate Risk Score = EF + PR + EC + MR

Using the criteria’s system described above, clinical equipment is categorized according to the following priority of testing and degree of risk:

High Risk

Equipment that scores 18–25 points on the criteria’s evaluation system. This equipment is assigned the highest risk for testing, calibration, and repair.

Figure 136-14 PIVIT’s Communications Center.

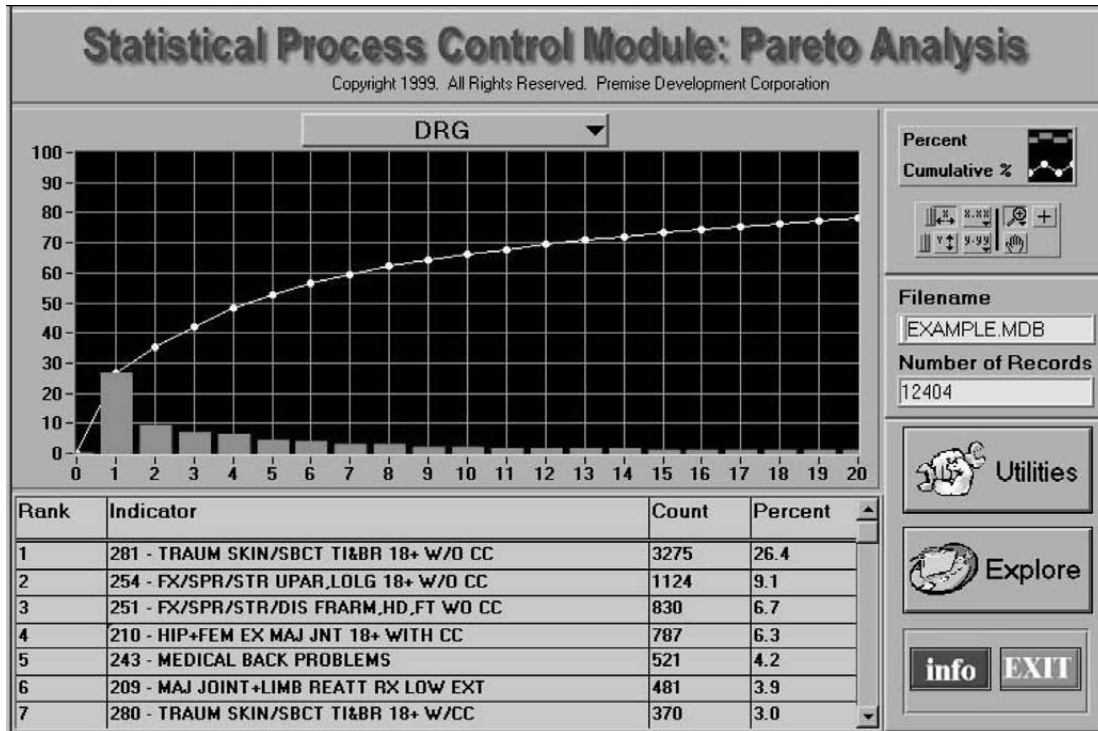

Figure 136-15 Statistical Process Control–Pareto Analysis of a sample trauma registry.

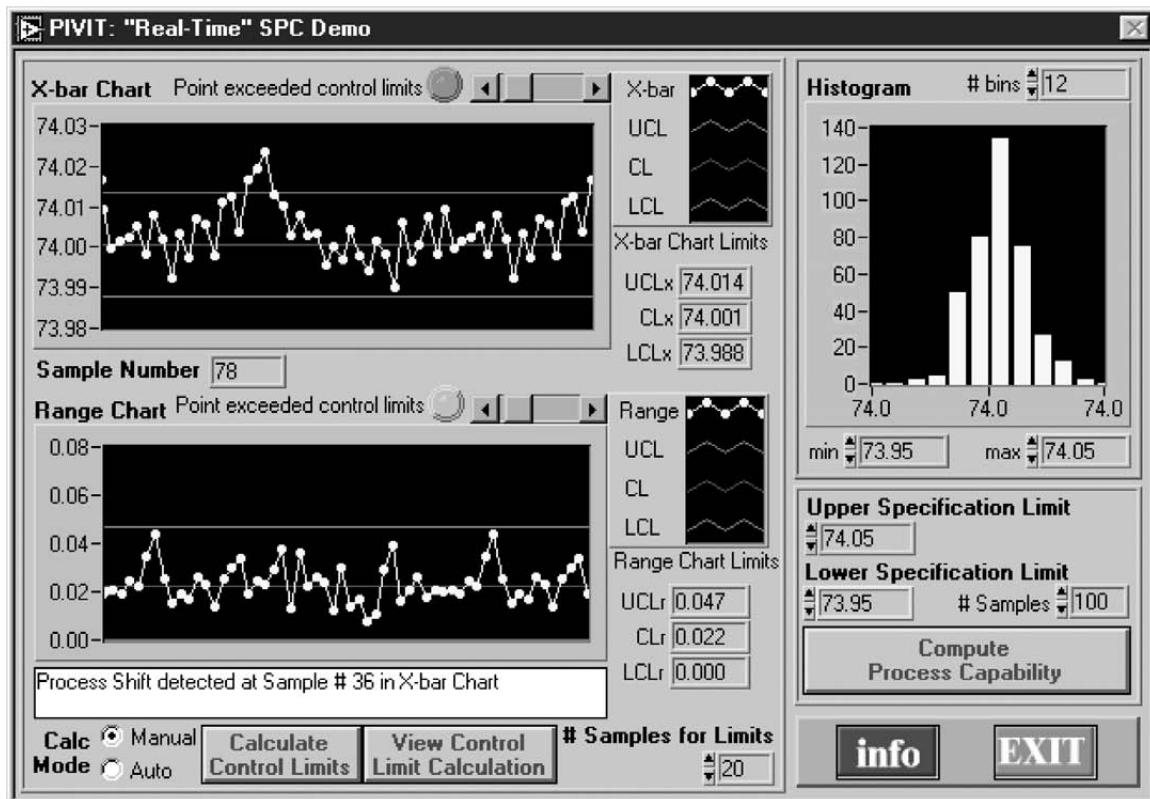

Figure 136-16 Statistical Process Control – "Real Time" SPC Application.

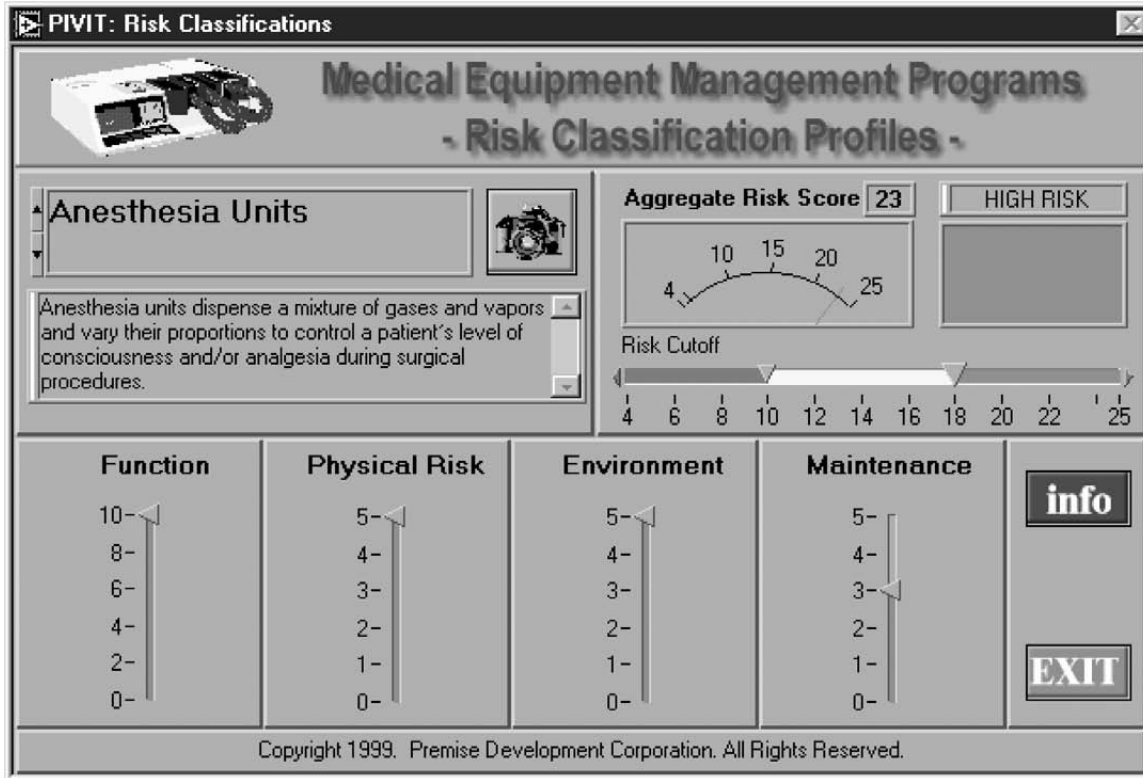

Figure 136-17 Medical Equipment Risk Classification Profiler.

Table 136-1 Equipment Function Ranking

<i>Risk Category I: Equipment Function (EF)</i>	
Point Score	Function Description
10	Therapeutic -Life Support
9	Therapeutic -Surgical or Intensive Care
8	Therapeutic -Physical Therapy or Treatment
7	Diagnostic -Surgical or Intensive Care Monitoring
6	Diagnostic -Other physiological monitoring
5	Analytical -Laboratory analytical
4	Analytical -Laboratory Accessories
3	Analytical -Computer and related
2	Miscellaneous -Patient-related
1	Miscellaneous -Non-patient related

Table 136-2 Physical Risk Ranking

<i>Risk Category II: Physical Risk (PR)</i>	
Point Score	Description of Use Risk
5	Potential patient death
4	Potential patient injury
3	Inappropriate therapy or mis-diagnosis
2	Equipment damage
1	No significant identified risk

Medium Risk

Equipment that scores 15–17 points on the criteria’s evaluation system.

Low Risk

Equipment that scores 12–14 points on the criteria’s evaluation system.

Hazard Surveillance (Gray)

Equipment that scores 6–11 points on the criteria’s evaluation system are visually inspected on an annual basis during the hospital hazard-surveillance rounds.

Table 136-3 Environmental Use Classification Ranking

<i>Risk Category IV: Environmental Use Classification (EC)</i>	
Point Score	Primary Area of Equipment Use
5	Anesthetizing Locations
4	Critical Care Areas
3	Wet Locations/Labs/Exam Areas
2	General Patient Care Areas
1	Non-Patient Care Areas

Table 136-4 Preventive Maintenance Ranking

<i>Risk Category III: Preventive Maintenance (MR)</i>	
Point Score	PM Frequency
5	Monthly
4	Quarterly
3	Semi-annually
2	Annually
1	Not required

Medical Equipment Management Program Deletion

Medical equipment and devices that pose little risk and scores less than 6 points can be deleted from the management program as well as from the clinical equipment inventory.

Future versions of this application will also consider “dynamic” risk factors such as user errors, mean-time-between failure (MTBF), device failure within 30 days of a preventive maintenance or repair, and the number of years beyond the American Hospital Association’s recommended useful life.

Peer Performance Reviews

The virtual instrument shown in Figure 136-18 has been designed to easily acquire and compile performance information with respect to institution-wide competencies. It has been created to allow every member of a team or department to participate in the evaluation of a co-worker (360-degree peer review).

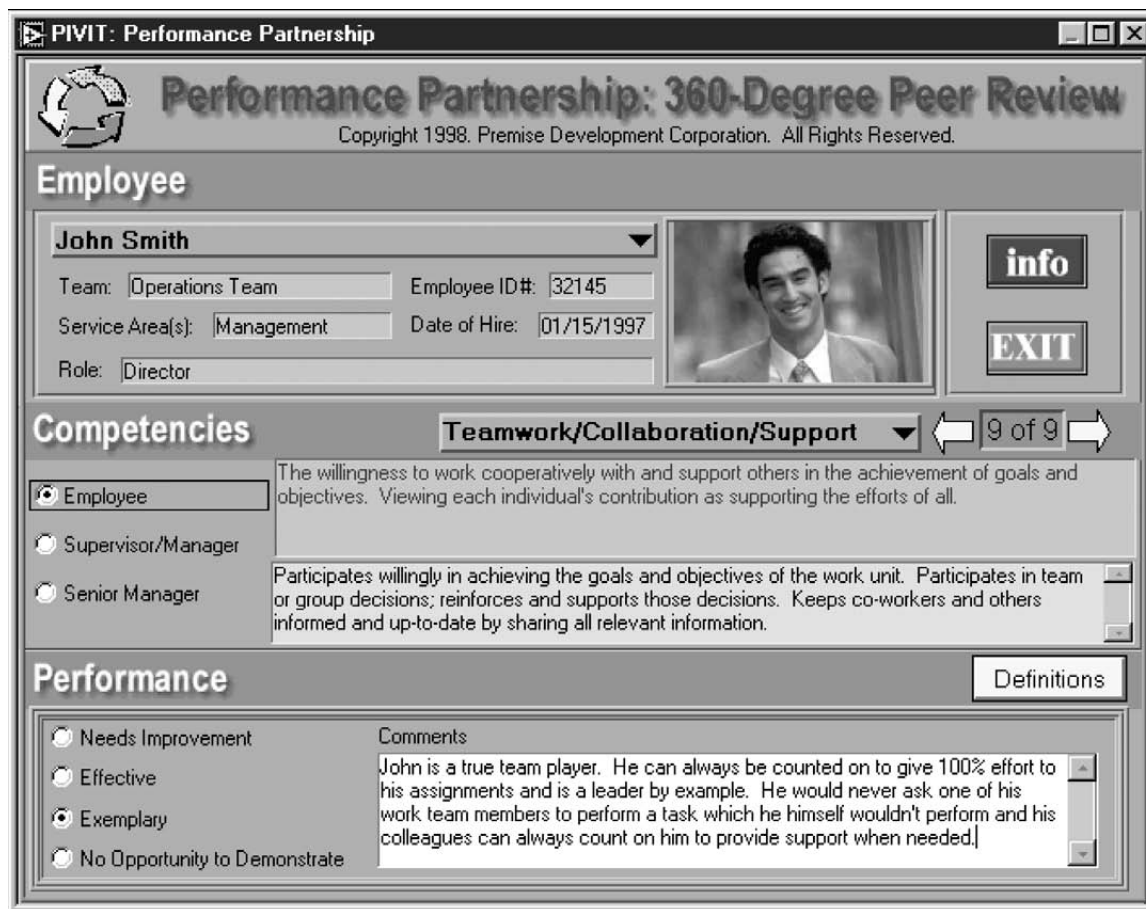

Figure 136-18 Performance reviews using virtual instrumentation.

Upon running the application, the user is presented with a “sign-in” screen where he or she enters a username and password. The application is divided into three components. The first (top section) profiles the employee and the relevant service information. The second (middle section) indicates each competency as defined for employees, managers, and senior managers. The last (bottom section) allows the reviewer to evaluate performance by selecting one of four “radio buttons” and also to provide specific comments related to each competency. This information is then compiled (with other reviewers) as real-time feedback.

Case Study #3: BioBench—A Virtual Instrument Application for Data Acquisition and Analysis of Physiological Signals

The biomedical industry relies heavily on the ability to acquire, analyze, and display large quantities of data. Whether researching disease mechanisms and treatments by monitoring and storing physiological signals, researching the effects of various drugs interactions, or teaching students in labs where they study physiological signs and symptoms, it was clear that there existed a strong demand for a flexible, easy-to-use, and cost-effective tool. In a collaborative approach, biomedical engineers, software engineers and clinicians and researcher created a suite of virtual instruments called BioBench.TM

BioBenchTM (National Instruments, Austin, TX) is a new software application designed for physiological data acquisition and analysis. It was built with LabVIEWTM, the world's leading software development environment for data acquisition, analysis, and presentation.* Coupled with National Instruments data-acquisition (DAQ) boards, BioBench integrates the PC with data acquisition for the life sciences market.

Many biologists and physiologists have made major investments over time in data-acquisition hardware built before the advent of modern PCs. While these scientists cannot afford to throw out their investment in this equipment, they recognize that computers and the concept of virtual instrumentation yield tremendous benefits in terms of data analysis, storage, and presentation. In many cases, traditional medical instrumentation is too expensive to acquire and/or maintain. As a result, researchers and scientists are opting to create their own PC-based data-monitoring systems in the form of virtual instruments.

Other life scientists, who are just beginning to assemble laboratory equipment, face the daunting task of selecting hardware and software needed for their application. Many man-

ufacturers for the life sciences field focus their efforts on the acquisition of raw signals and converting them into measurable linear voltages. They do not concentrate on digitizing signals or the analysis and display of data on the PC. BioBenchTM is a low-cost, turnkey package that requires no programming. BioBench is compatible with any isolation amplifier or monitoring instrument that provides an analog output signal. The user can acquire and analyze data immediately because BioBench automatically recognizes and controls the National Instruments DAQ hardware, thus minimizing configuration headaches.

Some of the advantages of PC-Based Data Monitoring include the following:

- Easy-to-use software applications
- Large memory and the PCI bus
- Powerful processing capabilities
- Simplified customization and development
- More data storage and faster data transfer
- More efficient data analysis.

Figure 136-19 illustrates a typical setup of a data acquisition experiment using BioBench. BioBench also features pull-down menus through which the user can configure devices. Therefore, those who have made large capital investments can easily migrate their existing equipment into the Computer Age. Integrating a combination of old and new physiological instruments from a variety of manufacturers is an important and straightforward procedure. In fact, within the clinical and research settings, it is a common requirement to be able to acquire multiple physiological signals from a variety of medical devices and instruments that do not necessarily communicate with each other. Often, this situation is compounded by the fact that end-users would like to be able to view and analyze an entire waveform and not just an average value. In order to accomplish this, the end-user must acquire multiple channels of data at a relatively high sampling rate and have the ability to manage many large data files. BioBench can collect up to 16 channels simultaneously at a sampling rate of 1000 Hz per channel. Files are stored in an efficient binary format that significantly reduces the amount of hard disk and memory requirements of the PC. During data acquisition, a number of features are available to the end-user. These features include Data Logging, Event Logging, and Alarming.

Data Logging

Logging can be enabled prior to, or during, an acquisition. The application will either prompt the user for a descriptive filename or it can be configured to automatically

Figure 136-19 A typical biomedical application using BioBench.

assign a filename for each acquisition. Turning the data-logging option on and off creates a log data-event record that can be inspected in any of the analysis views of BioBench.

Event Logging

The capacity to associate and recognize user commands associated with a data file may be of significant value. BioBench has been designed to provide this capability by automatically logging user-defined events, stimulus events, and file-logging events. With user-defined events, the user can easily enter and associate date- and time-stamped notes with user actions or specific subsets of data. Stimulus events are also date- and time-stamped and provide the user information about whether a stimulus has been turned on or off. File-logging events note when data have been logged to a disk. All of these types of events are stored with the raw data when logging data to file, and they can be searched for when analyzing data.

Alarming

To alert the user about specific data values and thresholds, BioBench incorporates user-defined alarms for each signal displayed. Alarms appear on the user interface during data acquisition and notify the user if an alarm condition has occurred.

Figure 136-20 is an example of the Data Acquisition mode of BioBench. Once data have been acquired, BioBench can employ a wide array of easy-to-use analysis features. The user has the choice of importing recently acquired data or opening a data file that had been acquired for comparison or teaching purposes. Once a data set has been selected and opened, BioBench allows the user simply to select and highlight a region of interest and to choose the analysis options to perform a specific routine.

BioBench implements a wide array of scalar and array analyses. For example, scalar-analysis tools will determine the minimum, maximum, mean, integral, and slope of a selected data set, while the array analysis tools can employ Fast Fourier Transforms (FFTs), peak detection, histograms, and X-versus-Y plots.

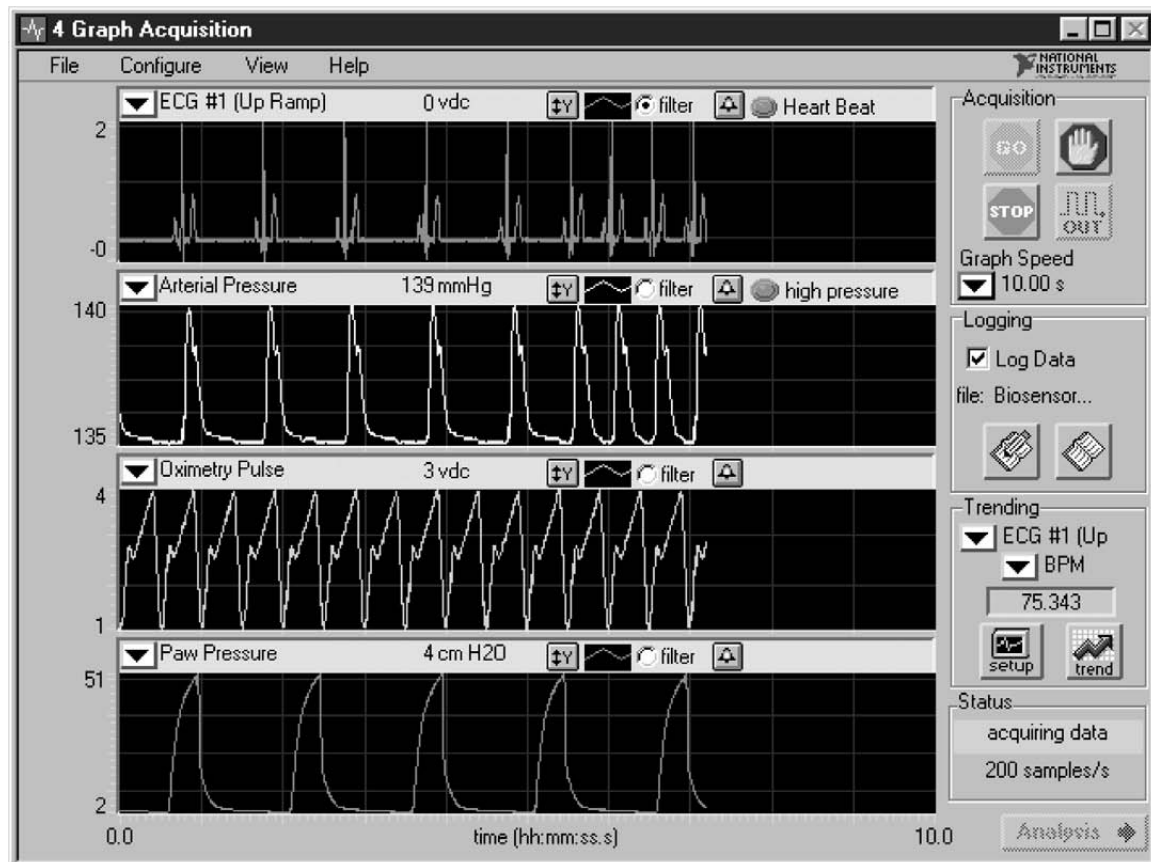

Figure 136-20 BioBench Acquisition mode with alarms enabled.

The ability to compare multiple data files is important in analysis, and BioBench allows the user to open an unlimited number of data files for simultaneous comparison and analysis. All data files can be scanned using BioBench's search tools in which the user can search for particular events that are associated with areas of interest. In addition, BioBench allows the user to employ filters and transformations to their data sets, and all logged data can be easily exported to a spreadsheet or database for further analysis. Finally, any signal acquired with BioBench can be played back, thus taking lab experience into the classroom. Figure 136-21 illustrates the analysis features of BioBench.

Case Study #4: A Cardiovascular Pressure—Dimension Analysis System

The intrinsic contractility of the heart muscle (myocardium) is the single most important determinant of prognosis in virtually all diseases affecting the heart (e.g., coronary artery disease, valvular heart disease, and cardiomyopathy). Furthermore, it is clinically important to be able to evaluate and track myocardial function in other situations, including chemotherapy, where cardiac dysfunction could be a side effect of treatment, and liver disease, where cardiac dysfunction could complicate the disease.

The most commonly used measure of cardiac performance is the ejection fraction. Although it does provide some measure of intrinsic myocardial performance, it is also heavily influenced by other factors, such as heart rate and loading conditions (i.e., the amount of blood returning to the heart and the pressure against which the heart ejects blood).

Better indices of myocardial function based on the relationship between pressure and volume throughout the cardiac cycle (pressure-volume loops) exist. However, these methods have been limited because they require the ability to track ventricular volume continuously during rapidly changing loading conditions. While there are many techniques to measure volume under steady-state situations, or at end-diastole and end-systole (the basis of ejection fraction determinations), few have the potential to record volume during changing loading conditions.

Echocardiography can provide online images of the heart with high temporal resolution (typically 30 frames per second). Because echocardiography is radiation-free and has no identifiable toxicity, it is ideally suited to pressure-volume analyses. Until recently however, its use for this purpose has been limited by the need for manual tracing of the endocardial borders, an extremely tedious and time-consuming endeavor.

The System

Biomedical and software engineers at Premise Development Corporation (Hartford, CT), in collaboration with physicians and researchers at Hartford Hospital, have developed a

sophisticated research application called the "Cardiovascular Pressure-Dimension Analysis (CPDA) System". The CPDA system acquires echocardiographic volume and area information from the acoustic quantification (AQ) port, in conjunction with ventricular pressure(s) and ECG signals to perform pressure-volume and pressure-area analyses rapidly. The development and validation of this system have led to numerous abstracts and publications at national conferences, including the American Heart Association, the American College of Cardiology, the American Society of Echocardiography, and the Association for the Advancement of Medical Instrumentation. This fully automated system allows cardiologists and researchers to perform online pressure-dimension and stroke work analyses during routine cardiac catheterizations and open-heart surgery.

The system has been designed to work with standard computer hardware. Analog signals for ECG, pressure, and area/volume (AQ) are connected to a standard BNC terminal board. Automated calibration routines ensure that each signal is properly scaled and that it allows the user to immediately collect and analyze pressure-dimension relationships.

The development of an automated, online method of tracing endocardial borders (Hewlett-Packard's AQ Technology) (Hewlett-Packard Medical Products Group, Andover, MA) has provided a method for rapid online area and volume determinations. Figure 136-22 illustrates this AQ signal from a Hewlett-Packard Sonos Ultrasound Machine. This signal is available as an analog voltage (-1 to +1 volts) through the Sonos Dataport option (BNC connector).

Figure 136-23 illustrates the measured parameters and the specific hardware used for this application. Although this application was initially developed on a Macintosh platform, the system can run on multiple platforms, including Windows 9x/NT/2000/XP. The CPDA also takes advantage of the latest hardware developments, and form-factors and can be used on either a desktop or a laptop computer.

Data Acquisition and Analysis

Upon launching this application, the user is presented with a dialog box that reviews the license agreement and limited warranty. Next, the main menu is displayed, allowing the user to select from one of six options as shown in Figure 136-24.

When conducting a test, an automated calibration sequence for the pressure and ultrasound signals (acoustic quantification) is generally performed. If the user elects not to perform a calibration, the most recent calibration values are accessed from the integrated calibration log. Pressure-calibration data are retrieved from a "lookup table" containing specific gain and offset values for a variety of different manufacturers' pressure monitors. The AQ calibration procedure involves "scaling" and "mapping" the display image signal over the -1 to +1 volt output range. Figure 136-25 illustrates the front panel for the Hewlett-Packard Sonos calibration procedure. Sequential instructions in the form of a scrolling string indicator, as well as dialog boxes, are also available.

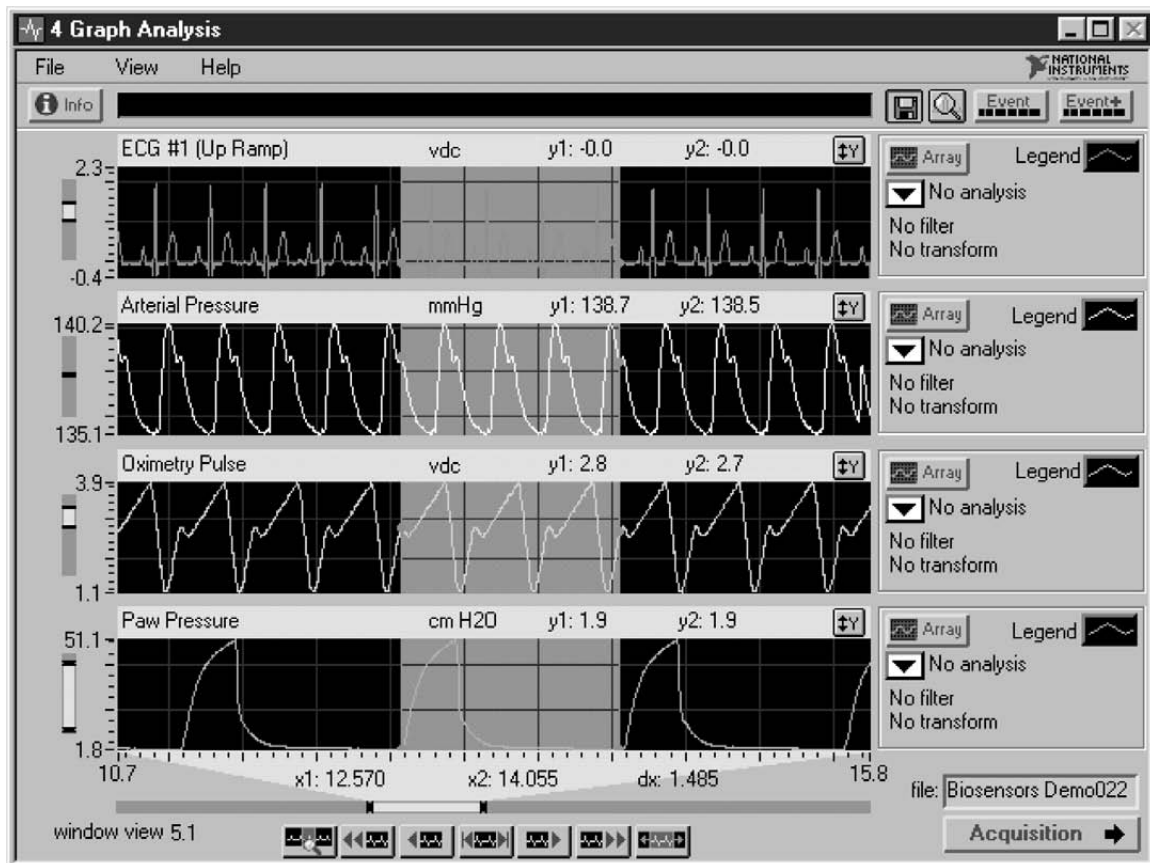

Figure 136-21 BioBench Analysis mode.

Figure 136-22 The Acoustic Quantification (AQ) Signal (Hewlett-Packard).

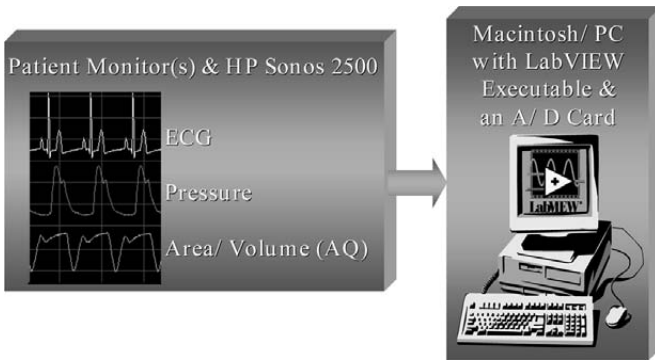

Figure 136-23 Schematic diagram of the cardiovascular pressure-dimension analysis system.

The default sampling frequency for each channel is 200 Hz. Data are typically collected for 20 to 60 seconds. The user is presented with a “Pre-Scan” panel to ensure that each signal is calibrated and tracking appropriately. When the user is ready to collect and store data, the “Cardiac DAQ” instrument is called (Figure 136-26). This sub-VI uses double-buffering to collect and display each channel for the predefined time. In order to maintain high temporal resolution, data are displayed in 10-second “sweeps.” An indicator is provided to display the instantaneous and total collection time.

Once data are collected, the user is presented with the “Data Selection” sub-VI to define a particular range of data to save to a file. This option allows the user to store only the portion or subset of data that are useful among the entire collected data set (e.g., the last 25 seconds of a 60-second array). The default setting will store the entire data set. Interactive cursors are used to interactively set the initial and final indices of the data subset for analysis, as illustrated in Figure 136-27.

Clinical Significance

Several important relationships can be derived from these signals. Specifically, a parameter called the “End-Systolic Pressure-Volume Relationship” (ESPVR) describes the line of best fit through the peak-ratio (maximum pressure with respect to minimum volume) coordinates from a series of pressure-volume loops generated under varying loading conditions. The

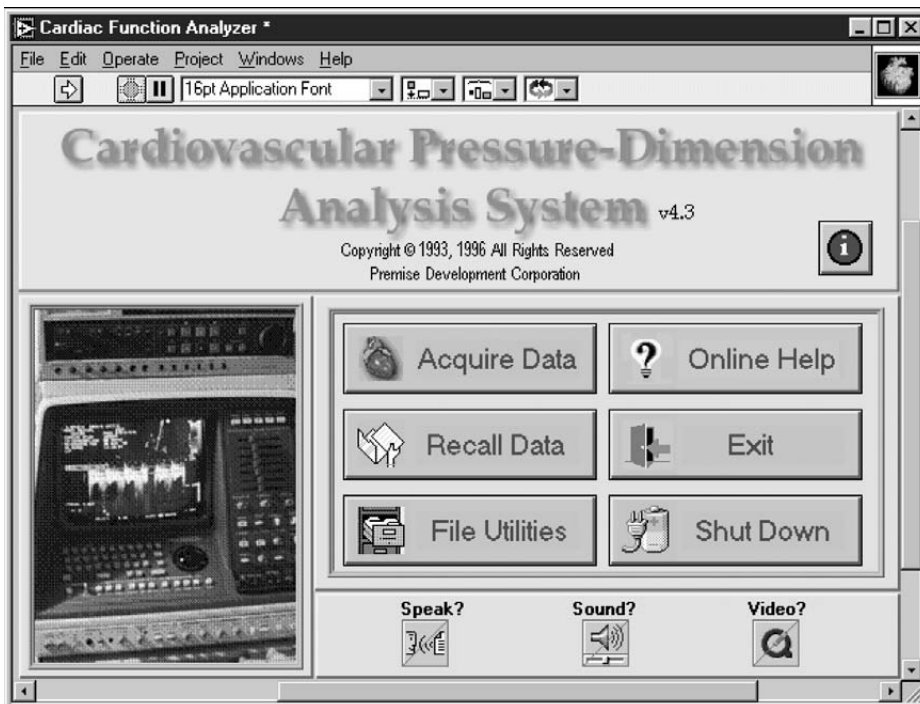

Figure 136-24 Cardiovascular Pressure-Dimension Analysis main menu.

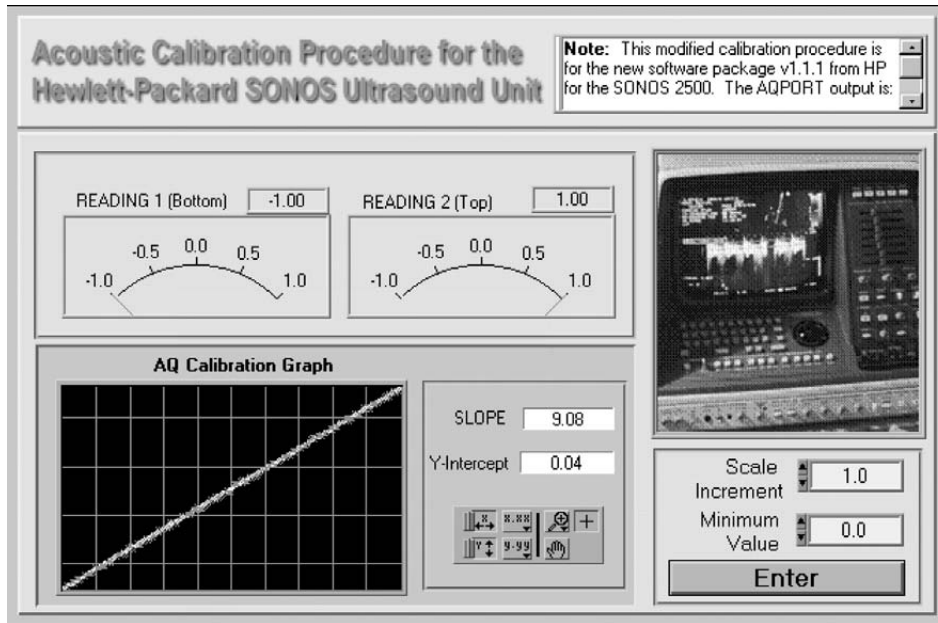

Figure 136-25 Hewlett-Packard's Sonos Ultrasound Machine Calibration front panel.

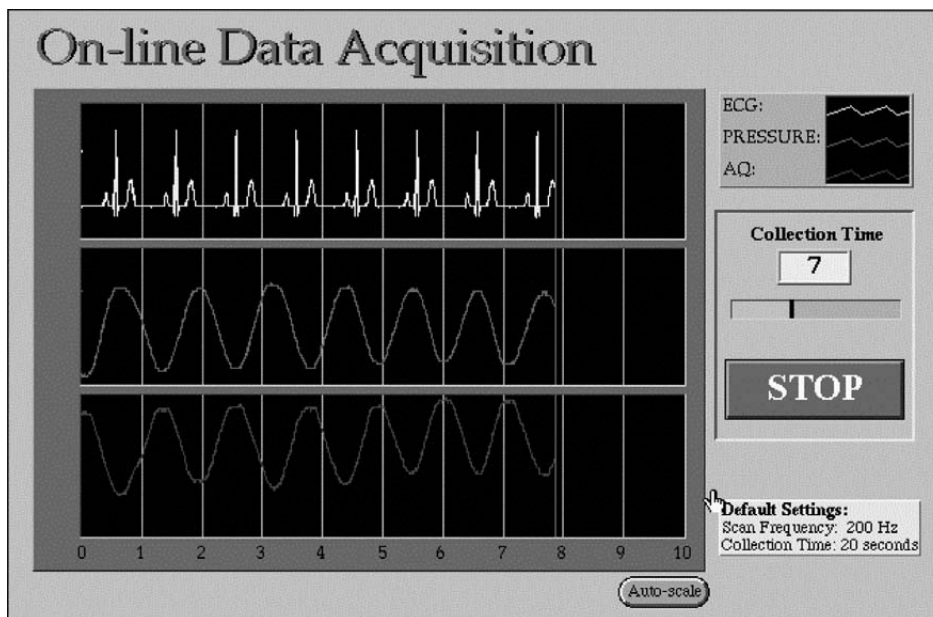

Figure 136-26 The Cardiac DAQ front panel.

slope of this line has been shown to be a sensitive index of myocardial contractility that is independent of loading conditions. In addition, several other analyses, including time-varying elastance (Emax) and stroke work, are calculated. Time-varying elastance is measured by determining the maximum slope of a regression line through a series of isochronic pressure-volume coordinates. Stroke work is calculated by quantifying the area of each pressure-volume loop. Statistical parameters are also calculated and displayed for each set of data. Figure 136-28 illustrates the pressure-dimension loops and each of the calculated parameters along with the various analysis options. Finally, the user has the ability to export data sets into spreadsheet and database files, and to export graphs and indicators into third-party-presentation software packages, such as Microsoft PowerPoint.®

Summary

Virtual instrumentation allows the development and implementation of innovative and cost-effective biomedical applications and information-management solutions. As the

health care industry continues to respond to the growing trends of managed care and capitation, it is imperative for clinically useful, cost-effective technologies to be developed and utilized. As application needs surely will continue to change, virtual instrumentation systems will continue to offer users flexible and powerful solutions without requiring new equipment or traditional instruments.

Virtual instruments and executive dashboards allow organizations to effectively harness the power of the PC to access, analyze, and share information throughout the enterprise. The case studies discussed in this article illustrate ways in which various institutions have conceived and developed "user-defined" solutions to meet specific requirements within the health care and insurance industries. These dashboards support general operations, help hospitals manage fluctuating patient census and bed availability, and empower clinicians and researchers with tools to acquire, analyze, and display clinical information from disparate sources. Decision-makers can easily move from big-picture analyses to transaction-level details while at the same time safely sharing this information throughout the enterprise to derive knowledge and to make timely, data driven decisions. Collectively, these integrated applications directly benefit health care providers, payers, and, most importantly, patients.

Clinical Engineers in Non-Traditional Roles

Eben Kermit

Biomedical Engineer and Consultant
Palo Alto, CA

What is the first image that comes to mind with the term “clinical engineer”? For many, it is a middle-aged male with a college education and an advanced degree who manages a department of technicians and support staff. The primary function of a clinical engineer is to oversee the repair and maintenance of the many medical devices used in a modern hospital. Often, the repair facility is on the basement level, near the boiler room or the morgue. There is no apparent reason for this, but it is often the case. There is typically a line-up of equipment awaiting repair, often spilling into the hallway. Intravenous pumps, wheelchairs, and beds are often the first clue that one is approaching the clinical engineering department. Parts may have been ordered last week, but have not been received and installed. The office, or repair area, is likely to be littered with tools, cleaning supplies, assemblies, and sub-assemblies. Despite the clutter, there is a level of organization, distinguished by the individual technicians and the types of equipment under repair. The office contains reports and files, both paper and electronic, of repair orders, repair histories, safety inspections, and JCAHO audits. These documents are always present and always in a state of review and input.

There is also a steady stream of visitors. Some visit in person, others by telephone, and still more by computer. They are the “customers” to the clinical engineering office. They want to have a device repaired, ask how to use a new or forgotten item, or determine whether a screw driver or epoxy adhesive is available for a fix-up.

Welcome to the world of the hospital-based clinical engineer!

Of course this description is fictional, generalized to a great degree, and colored based on the author’s experiences both working in and visiting many hospitals. Many situations are quite different. The definition of a clinical engineer is broad and inclusive and not limited to hospital-based job descriptions. The definition adopted by the American College of Clinical Engineers (ACCE) is, “A professional who supports and advances patient care by applying engineering and management skills to health care technology” (Bauld, 1991). The following is taken from the ACCE description of a clinical engineer:

“As clinical medicine has become increasingly dependent on wider use of highly sophisticated technology, and the ever more complex equipment associated with it, the clinical engineer’s role in the health care system has continuously evolved as well. Serving initially as the health care provider’s equipment manager, today’s clinical engineer has become the technology officer and strategist, helping health providers and industry to plan for the manufacture or acquisition of technology, then ensuring its continued, safe and efficient utilization through a well-planned program of user training, maintenance and quality assurance.

In addition, a clinical engineer’s education provides a solid understanding of the physical sciences necessary to apply those principles to the design and construction of instruments and devices for health care. With additional education, training, and experience in the life sciences and management, the clinical engineer is especially qualified for a variety of indispensable roles in the realm of health care, industry and academia.”

Please note that there is not an expectation, nor is there a requirement, to work in a hospital, clinic, or other health care facility. The only requirement is the application of engineering skills for the improvement of health care. Given this interpretation, what other roles are filled by clinical engineers? What else can clinical engineers do besides work in a hospital or contract repair facility?

Ergonomics, the design of systems and controls that fit the human body, is one domain occupied by clinical engineers. The automotive, consumer electronics, and aerospace industries all use clinical engineers to design products that fit switches to fingers, levers or wheels to hands, and pedals to feet. All control interfaces must fit people for dimensions, strength, and reach, and must logically group controls together to avoid accidental selections. Human factors engineering, whether for seating, displays, or controls, is a sub-specialty of clinical engineering. Most people do not realize that handles, doorknobs, gearshift grips, and bathtub faucets must all be designed to fit the human hand. Hands come in a range of sizes and designers must take this into account. Buttons on a car radio must be activated without impediment, even if the driver is wearing gloves, or can not see

the controls due to darkness or concentration on traffic. Some engineers intuitively incorporate human factors into their designs; others are formally trained in specific college courses on this subject (see Chapter 83).

Another subspecialty of clinical engineering is that of expert witness. Attorneys in legal hearings or trials involving a medical device frequently retain clinical engineers as expert witnesses. Sometimes an accident or injury that results in a lawsuit; other times corporations claim of infringements of design elements and patent claims. The role of the expert is to teach or instruct the judge and jury. An expert may be asked to offer opinion on the typical use of a device or to project what might happen in hypothetical situations. The expert clinical engineer usually has sufficient educational background and experience (plus an advanced degree) and often a professional license in order to qualify as an expert for legal purposes (see Chapter 13).

Clinical engineers may also be called upon to investigate accidents involving medical devices and injury. In this role, they use analytical skills to understand the situation and how the attributes of a device design contributed to the injury. In the best tradition of Sherlock Holmes, gathering the facts, examining the clues, and arriving at the explanation is a form of clinical engineering. (See Chapter 64.)

A clinical engineer may be an “inventor” and “product designer” (see Chapter 82). Clinical engineers often use their logical and insightful reasoning to develop a new medical device or procedure, or improve on one that exists. For example, pulse oximetry uses a pair of light emitting diodes and a phototransistor to measure the absorbed light after it passes through tissue. The measurement is extremely useful as a measure of the amount of oxygen in the tissue. This technology was developed after an engineer recognized that a medical procedure for measuring cardiac output using a dye and photo detector was sensitive to changes in background absorption shifts due to changes in oxygen saturation. This was the foundation for the use of pulse oximetry, a transformation in health care.

Engineers are paid to create products and develop applications. The medical device industry is no different than other areas of product design. Engineers, typically working in small groups or teams, play a major role in the creation of ventilators, bandages, pulse oximeters, infusion pumps, artificial hearts, and CT scanners. Multiple elements must be addressed for a product design to succeed. The fundamental application (requirement) must be identified to ensure there is demand (market) for the device. In addition, the product must meet regulatory standards. Prior to the introduction of any medical device, a validation/verification for both product design and process, including failure mode and effect analysis (FMEA), must be planned and executed to completion (Stamatis, 1995). Building prototypes differs from building large numbers of devices for distribution to the end user(s). Plans and designs for manufacturability become increasingly important as quantities increase. Fixtures, molds, assembly of fasteners, welds, and even packages must be produced in a way that is efficient and that reduces the likelihood of a manufacturing error during assembly.

Clinical engineers can also work in regulatory affairs. In the U.S., medical devices came under the purview of the U.S. Food and Drug Administration (FDA) in 1976 (see Chapter 126). In Europe, CE marking of products has been required for general sale and distribution of medical devices since 1996 (see Chapter 125). Clinical engineers often are key players in the review and approval processes of medical devices. The FDA requirement that medical devices be safe and effective is mandated in the US, and the regulatory process is intended to assure the public that medical devices work correctly and as designed.

Many clinical engineers seek careers in research and scientific development. They may be affiliated with a university, government center, or an industrial “think-tank.” Familiarity with the scientific method—postulating a theory (hypothesis), designing an experiment with controls, collecting data, performing data analysis, and logically summarizing results—is the process expected for publication of findings at conferences or in journals. Clinical engineers are well suited to this process due to formal training in analysis in undergraduate or advanced degree programs.

Clinical engineers can and often do become entrepreneur. The skills and leadership abilities necessary for creating a business are complex. Finding money, researching intellectual property (patents), recruiting other engineers, scientists, programmers, or designers to develop a new product takes much commitment. Planning a marketing and sales strategy, finding a laboratory, building, or office space, writing contracts for sub-assembly, packaging, sterilization, etc., must also be considered (see Chapter 140). Also, managing investors, distributors, and sub-contractors, and, if the company grows large enough, an initial public offering (IPO) or acquisition by another firm are the responsibilities of the CEO/entrepreneur.

Rehabilitation is another area in which clinical engineers can use their skills and experience with a wide variety of devices ranging from simple to complex. A set of crutches is a simple but subtle device. The crutches must be able to support the patient’s body weight, but also must be comfortable in the hands, accommodate a range of lengths, and must be durable, lightweight, inexpensive, cosmetically acceptable, possibly collapsible for storage, and capable of being manufactured in large quantities. All of these constraints have collapsed the number of design styles and materials to the few versions in use today.

Wheelchairs come in a wide variety of styles and shapes, and many more choices exist than for crutches. Some wheelchairs are motorized, others are designed for sport events, and still others include special features for climbing stairs or curbs. Some are recline. Some wheelchairs are essentially miniature electric carts, intended for travel over several miles on pavement or rough terrain. Patient support, controls, padding, footrests, brakes, weight, and cosmetics, e.g., plastic molded fairings, all must be designed. While the goal of mobility, wheelchairs are still relatively simple, and a single design is often acceptable for many users (see Chapter 95).

Artificial limb design involves both dedication to detail and craftsmanship. Each prosthetic (or orthotic) must be “custom fit” for every patient. As with wheelchairs, a wide

range of choices and trade-offs are available. For example, an artificial below the elbow device may be a simple “hook” with a grasping claw, often selected by patients over more cosmetic motorized “hands”. The reasons are subtle. While the “hook” does not look like a hand, it is quite functional. It is durable, easy to operate, works even (or despite) a dead battery, and can be used to pull muffins out of a hot oven without melting. There are also many adaptations, such as “hands” with hair brushes, ping-pong paddles, extension graspers, or *jai alai* baskets, which can be easily connected and disconnected with a simple retention coupling. Yet, despite these “advanced” features, the claw hook is the most common selection. The point is that design and patient acceptance must be in accord. Engineers continue to play a key role in filling the need for simple, well-designed devices, while providing patients with a range of prosthetic choices.

Implants or implantable devices bring a number of design issues into focus. Not only must this class of device be bio-compatible and sterile to go inside the body, it must also be durable in a highly corrosive environment. Consider vascular stents. These devices are metallic structures, with a complex and intricate pattern of cut-outs within a tubular shape. The stents are inserted inside the blood vessel in their collapsed state via a catheter, and advanced to the desired position. Often, a balloon catheter device is used to radially expand the tubular latticework. Once expanded, the stent keeps the vessel patent (open to flow). The design considerations are multiple. Not only must be bio-compatible, the latticework must be capable of radial expansion and yet not break, collapse, or deform. The device must be ductile enough to expand. Fibrin deposits, blood flow patterns, and clot formation are causes of device failures, and much research focuses on refining designs that are robust and resistant to occlusion. Also, it may be difficult or impossible to retrieve a device once it is deployed into the body, so the design engineer must conduct extensive testing, modeling, and validation prior to release of the device.

Teaching and education is a small but important niche sought by some clinical engineers (see Chapters 68 and 69). Often the teaching component is obvious, if clinical engineers are university professors or involved in academic research. However, many clinical engineers teach training seminars, give in-service lectures or classes, or travel abroad to developing countries to share knowledge and experience (see Chapters 70 and 71). Teachers can find great satisfaction in passing on methods and tools to others.

The military (directly or via sub-contractor firms) uses engineers extensively for research and the design of systems to protect soldiers from inhospitable environments (see Chapter 9). High-performance aircraft can pull G-forces that are greater than the limits of the human pilots. Undersea divers must have a respiratory gas mixture at high pressure that allows them to safely explore the ocean and its floor. In space flight, factors including artificial environment, energy management, waste disposal, exercise, “space sickness” or nausea must be considered and factored into the designs of space suits, submarines, tanks, space craft, and airplanes.

Space suit design is an apt example of clinical engineering. Space suits must meet many requirements to be effective. They must protect the human occupant from the hard vacuum of space, provide a breathable air mixture, keep the astronaut cool or warm, provide communications, and be lightweight and flexible. Engineers have been refining space suit design for decades, and materials and features continue to improve.

Telemedicine was once thought to be something from science fiction. Today, patients located in a rural clinic can “consult” with an expert in an urban medical center hundreds of miles away via a “telemedicine” link (see Chapter 101). Communications continue to improve and now can frequently support the transmission of clinically useful images and data. Soon, the ability to palpate the patient may be possibly via a robotic hand with tactile sensors and feedback servers. Someday, an astronaut in a spaceship may use telemedicine to receive medical care while traveling to the stars.

Engineers love robots because robots can perform tasks that either are repetitive or require superior precision. Try to make a screw thread with a steel rod and a hand file is much different from doing it with a lathe and motorized lead thread-cutting attachment. Orthopedic surgery for hip-socket replacement requires a precise match between the cavity in the femur and the spike of the orthotic. A robot creates the cavity with finer precision than the human surgeon. Stereotactic location used for neurosurgery can also be facilitated by the use of robots and space frame locators. Robots can also serve as couriers in hospitals; they never take a day off, call in sick, or demand a raise, even when called on at 2:00 a.m. to deliver materials.

The areas of interest for clinical engineers are limitless. The diverse fields described here merely reflect the complex interrelation of science, physics, materials, electronics, optics, computers, physiology, manufacturing, statistics, chemistry, anatomy, and mathematics that collectively form the practice of clinical engineering as it applies to the diverse set of problems of patients and health care.

If it were simple, anyone could be a clinical engineer, but it is not simple. This is both the challenge and the reward.

In conclusion, a wide variety of roles exist for clinical engineers. Some are based in the hospital, others in government or university settings, and many more in businesses. This field is truly international in scope, since technology knows no boundaries at borders. From the depths of the ocean to the vastness of space, clinical engineers have many diverse roles beyond working in hospitals.

Clinical Support: The Forgotten Function

Stan Scahill

Director of Biomedical Engineering
Concord Hospital
Concord, New South Wales, Australia

I recently read in the *Land* newspaper about the country town of Coolah, New South Wales. In 1995, the town was in serious decline following the closure of its main industry, saw milling. Town leaders called public meetings and undertook a strengths, weaknesses, opportunities, and threats (SWOT) analysis. The town residents realized that the tourist dollars were a way to keep people in the district. The town required beautification and an attraction, so the Coolah Spring Garden Festival was established. The town's main street and surrounding areas were refurbished, old heritage buildings were painted, and residents developed their gardens. The first spring festival raised \$20,000. The second raised \$30,000. This money was poured back into the town's development. This year the money raised will be going to the development of self-care units for the aged. The town has an interesting motto. "If you want a job well done, you have to do it yourself."

When I began working in hospital biomedical engineering 30 years ago (the term clinical engineering had not yet been coined), biomedical engineers and technicians were the technical wizards who were ushering in the new semiconductor technology. This advance enabled the medical profession to start measuring the electrical and physiological activity of the human body.

Alex Watson, David Jones, Don Melley, Richard Troughear, Rowley Hilder, Bruce Morrison, and Martin Dwyer were a few of those heavily involved in research in the fields of cardiology, neurology, psychology, and psychosurgery. We were mostly laboratory-based, but took our developing skills and knowledge into the clinical environment as well.

I will never forget the early Telectronics cardiac monitors, the HS1 and HS2, which were basically modified oscilloscopes. Rowley and I used to manufacture reusable ECG electrodes from small blue disposable electrodes. When the lead wire broke, a press stud was added and it was back in action. The electrode was attached with a double-sided adhesive disc and filled with ECG gel. Innovation and simplicity were the hallmarks of the day.

We designed, constructed, and tested our own equipment. Rowley would often have a device housed in a cardboard box or a cooking tray. Lawrie Knuckey from Melbourne would often tell of the manufacture of epoxy encased pacemakers and catching the tram to the Children's Hospital to implant them. We were unregulated and willing to try anything. We had the knowledge.

As electronics developed and science education for medical and nursing staff improved, engineers were muscled out of the clinical arena and soon became the repair team because we knew what happened inside the black box. The engineers and technicians in operating rooms and the clinics became centralized in biomedical engineering. Life had become simple. Our duties were confined to testing, safety assurance, purchasing, repairing, and fighting off independent service organizations. We became the service engineers with infrequent forays into the clinical environment.

However, service engineers may face extinction. With modern construction techniques you will not be able to repair boards. Board replacement will be the order of the day, and clinical engineers can not repair boards made with modern construction techniques. In addition, the equipment will probably be replaced. It is cheaper to replace a hand held oximeter than to repair it, and highly paid technical staff and engineers will no longer be needed to manage servicing.

What is our future? Let us do what the town of Coolah did and conduct an SWOT analysis on clinical engineering.

What are our strengths?

- Knowledge. Engineering, staff, equipment, clinical
- Multi skilled. Electronic, mechanical, computer literate
- Innovative. Can improvise, source alternate supplies
- Onsite. Generate quick response
- Support. Clinical support for new procedures

What are our weaknesses?

- Politically inept. Do not dance with the power brokers
- Inadequate clinically trained staff.

- Lack of organizational freedom.
- Poor self promotion.

What are our opportunities?

- Information technology
- Communications
- Clinical expertise
- Equipment development
- Research

What are our threats?

- External independent service organizations
- Predatory biomedical engineering services
- Limited budgets
- Internal self destruction due to the following:
 - Lack of knowledge
 - Lack of vision
 - Poor management skills

I will focus on the opportunity for knowledge. We are electronic and mechanical engineers and technicians in the life sciences. We should have an in-depth knowledge of ones engineering skills as applied to the medical environment. This gives us a uniqueness and advantage over other staff and external service groups.

Clinical engineering's actual clinical involvement is limited in many hospitals because engineers have failed to sell to our health care partners the fact that our knowledge base can be invaluable in the clinical environment. Clinical engineering has become a forgotten function.

However, I have observed that new opportunities are opening up for clinical engineers in the clinical environment. Modern medical equipment and devices have become more complex, and a modicum of technical knowledge is no longer adequate. Operator training has focused on the function rather than the system, leading to difficulties in fault resolution.

One complex device that comes to mind is the modern pacemaker. Outwardly, it is simple, but the technical knowledge of a clinical engineer or technician is invaluable when it is not performing as expected.

I will be employing a resident technician in the operating room (OR). What I have discovered is that the amount of equipment, the different types of equipment, and the systems built around equipment, are too complex for the nursing staff. They want to nurse, not find fault with equipment. Equipment malfunction may be due to a technical fault, an incorrect button push, or a reprogram of the equipment.

A senior surgeon at my establishment has calculated that a half-hour delay in operating room time costs a hospital more than \$3000. Some of my colleagues suggest that there is insufficient work for a technician, but if the technician becomes involved in setting up rooms, testing the equipment before the surgery, rearranging the equipment to suit the surgeon, conducting safety tests, calibrating equipment, supplying printers with toner and paper, and managing repairs, I believe that there is adequate work. Many faults on anesthetic equipment are due to incorrect settings by the operator. Clinical engineers can provide onsite help.

When the anesthetist complains that the invasive mean pressure differs from the mean noninvasive blood pressure (NIBP) mean, onsite assistance may be available in the form of a clinical engineer. This person will become invaluable, and when he or she is not there, the main clinical engineering department will be expected to support the OR. This may become inconvenient, but it will happen when clinical engineers become indispensable, which many engineers want.

Quality improvement is another aspect of clinical engineering presence in the clinical area. How many times have you observed a video endoscopy procedure in the OR and seen the surgeon struggling with a poor image simply because the automatic gain control was turned off? A clinical engineering staff must be trained to observe procedures as well as equipment.

If any medical device is faulty, fix it or send it for repair. If a procedure is hampered by technical difficulties, either fix it or refer it. Near enough is never good enough.

I believe we must develop partnerships with clinical care providers. We can provide advice and technical support and we can be visible, but not threatening. A clinical partnership we have established with units is to observe what they do and provide engineering input when necessary to provide a safer, better working environment.

In my hospital, we are developing an "over-bed support" for the intensive care unit (ICU) so that ventilators and infusion devices can be attached to the bed when it is necessary to transport the patient to the OR, radiology, or nuclear medicine. Presently, several nurses are required to push the stretchers and intravenous (IV) poles. This over-bed support device can be attached and removed by anyone by using existing bed controls.

My department has two additional projects in development to aid patient care. The first is a trolley that attaches a large transport ventilator to the foot end of an ICU bed, using the bed's own up and down controls to lift the ventilator both on and off the trolley. Similar trolleys will be kept in OR and radiology so the patient can be transported with the ventilator when the patient is transferred to CT. The second item is an air bag lifter, which helps to position wheelchair patients in front of an image intensifier for swallowing studies. The medical air is used as the power source.

Clinical engineers have invaded neurology as well. My hospital is close to high-powered radio transmitters, and the clinical engineering department moved to a different location. It had not been shielded according to my instructions and consequently no procedures could be undertaken due to radio frequency (RF) breakthrough. Remedial repairs were out of the question as the budget had already been consumed. The solution was roof sarking.

I stapled sarking on the wall between the transmitter and the equipment and the RF disappeared. This process also gave me the opportunity to observe the engineers' techniques and suggest improvements.

I am investigating the effects of shielded (versus unshielded) recording leads. Neurology departments regularly measure microvolt signals with unshielded, excessively long leads, and continually battle interference. We would not attempt to do this with our high-fidelity audio systems, so why do it in the clinical environment? The fact that filters minimize the effect of interference is insufficient excuse for poor practice.

I have developed IS with nursing administration as well. Many of our patients are elderly and suffer from decubitus ulcers if they are bedridden for long periods of time. I have been commissioned by the director of nursing to develop a device that could resolve this problem and costs less than \$150. I have two devices ready for testing. The case is a \$6 fishing tackle box, and the control valve uses a surplus microwave oven motor and a fish tank pump. The total cost is less than \$75.

Clinical engineers have developed continuous positive airway pressure (CPAP) machines using surplus oxygen-air blenders, with savings of \$30,000 to the hospital. The management appreciates this effect the budget.

Research alliances include the following:

- Gait analysis
- Infection minimization using ozone
- Bed pans

Clinical engineering should cease to be a forgotten function and become an area of new opportunities, not necessarily with primary patient care, but through partnerships with hospital departments for either direct or indirect involvement with patients. For example, clinical engineering may train staff more thoroughly than the product sales representative can train them.

Clinical engineering should be seen as the department that exists to improve patient care and to make the working environment less arduous and hazardous.

We veteran engineers are responsible for passing on our knowledge to our replacements. There will be a considerable changing of the guard in the next 10 years, so it is important we share our 30-plus years' worth of knowledge. Clinical engineering staff must be trained, since many of the younger staff members have not had the clinical exposure or experience of an older engineer or technician. I firmly believe that if your department is an integral part of patient care, threats of extinction by financial bureaucrats no longer exist. The hospital's chief executive officer should be your strongest supporter.

If you are seen as knowledgeable, you become indispensable, and your future will be more secure against internal threats.

Postmarket Surveillance and Vigilance on Medical Devices

Michael Cheng

Health Technology Management
Ottawa, Ontario, Canada

Concerns of Postmarket Surveillance and Vigilance

The current emphasis of the GHTF Study Group 2 seems to be mainly on high-risk issues such as those associated with cardiovascular devices or implants. However, statistics from the 2001 Adverse Incident Report from the Medical Devices Agency, United Kingdom (<http://www.medical-devices.gov.uk/>), have revealed that adverse events associated with low-risk devices such as those used for injection, drainage and suction, and daily living have significant adverse events (MDA, 2001). Adverse events from low-risk devices can be just as injurious and fatal as those from high-risk devices. For example, a suction device that malfunctions during surgery, or a patient hoist that fails, can result in serious injury to the patient. Moreover, low-risk devices are much larger in number, and they serve health care worldwide.

All founding members of the GHTF have mandatory requirements for manufacturers or their representatives to report to regulatory authorities all device-related incidents that have resulted, or could result, in serious injury or death. In the United States, some EU member states, and some Asian countries, mandatory-problem reporting is extended to users (see Chapter 126). However, problem reporting in the field of medical devices has become a controversial issue. There are concerns from the users and the manufacturers.

The medical device regulations of the five founding members of the Global Harmonization Task Force (Australia, Canada, the European Union (EU), Japan, and the U.S.) are based on the philosophy of risk management (see Chapter 124). No amount of premarket regulatory scrutiny can predict all possible device failures, and it therefore is essential to have continued assessment of, and vigilance for, the safety and performance of medical devices in use. Thus, the regulations require post-market surveillance and vigilance (see Chapters 125 and 126). One important requirement is adverse event reporting to regulatory authorities for the possible dissemination of information to other users in order to reduce the likelihood of repetition of adverse events. Improvements in post-market surveillance and vigilance are necessary. Such improvements can be effected through the expertise of clinical engineers and biomedical equipment technicians, particularly in the area of adverse event reporting.

The Global Harmonization Task Force (GHTF) primarily comprises representatives of manufacturers and government regulators. Noticeably absent are managers, users, and maintainers of medical devices. Within the scope of the GHTF, CEs and BMETs could make contributions of particular importance to developing countries where conditions are frequently quite different from those of the industrialized countries.

Some users are concerned that the information given in medical device problem-reporting might become an institutional or personal legal liability if it turns out that the problem was actually caused by the incorrect use of the device. Sometimes users are discouraged by their superiors to report problems when the cause of the problems is unclear. Institutions are also concerned about possible legal actions that can be taken by manufacturers when the latter feel they were wrongly implicated in device-problem reports. Some manufacturers are concerned that if the media reports news of an adverse event prematurely, they might cause unnecessary alarm to the public, and possible damage to the reputation of the manufacturer. Adverse events can require in-depth, thorough inquiries that take considerable time.

There is often a general reluctance to report problems associated with the use of medical devices to the regulators, even though such reporting is mandated by law. Some regulatory authorities in Europe, North America, and Asia are experiencing a lack of co-operations from device users and manufacturers. The CE and BMET, however, are in a position to provide a solution to this dilemma (Dyro, 2003).

The Role of the Clinical Engineer and Biomedical Equipment Technician

The assurance of safety and performance of medical devices is the responsibility of the clinical engineer and biomedical equipment technician within most health care facilities. The job descriptions of a clinical engineer and biomedical equipment technician normally include responsibilities such as technology assessment, selection, acquisition, installation, and maintenance, as well as consultation for hospital staff on safe and effective use of medical equipment. Thus, when an adverse event associated with medical devices occurs, the clinical engineer or technician (and, if available, a representative from the manufacturer) would normally conduct an investigation to determine whether there has been a device failure or use error (see Chapters 13 and 64). If it is a user error, it is the CE's or BMET's duty to inform or instruct the user. If it is a device problem, there should be no hesitation to report to the manufacturer and the regulator.

The following pertains to developing professionalism in handling this task.

- One major reason for a general apprehensiveness about problem-reporting is the traditional culture of "people blaming" rather than "problem solving." People are reluctant to report a problem because they fear that they may be held responsible for it. In reality, when an error occurs, blaming an individual does little to make the system safer or to prevent someone else from committing the same error. Therefore, one should use a systems or process approach to identify and solve problems (see Chapter 59). The focus must shift from blaming individuals for past errors to preventing future errors by designing safety not only into the device but also into the procedure of its use. This is consistent with the quality and continuous improvement principles. The report of The Institute of Medicine of the National Academy of Sciences of the USA provides valuable insight into the problem and suggests ways in which errors can be identified, reported, and analyzed in a constructive way. See "To Err Is Human—Building a Safer Health System" http://books.nap.edu/html/to_err_is_human. (Kohn et al. 2000)
- The fact of user interface in the use of medical devices brings out another aspect of medical devices with which the clinical engineer and biomedical equipment technician are familiar—the human factor in human-machine interface. Frequently, use errors occur because a machine was not designed with proper concerns for ergonomics, and use errors could have been prevented or minimized if the design had incorporated human factor engineering principles. Therefore, a use error should be followed up with an investigation that can determine whether possible corrective actions in the design are necessary. With their technical knowledge of medical devices and intimate user experience, the clinical engineer and biomedical equipment technician are again in positions to make positive contributions. An excellent reference on this subject is available on an FDA web site: <http://www.fda.gov/cdrh/humfac/1497.html>.
- The investigation of an adverse event is a complex task that often requires a multidisciplinary team approach (see Chapter 64). The clinician who uses the device, the device operator, and the manufacturer all should be involved in the investigation. Functioning as an effective team member are skills that can be developed. A good pocket guide for team members is "The Team Memory Jogger," a GOAL/QPC publication (<http://www.goalqpc.com/>) (GOAL/QPC, 2001).
- Discretion and confidentiality are, of course, essential. It is critical that the dissemination of information to the media be handled with discretion so that it does not damage the reputation of a health care professional, the health care institution, or the medical device company.

More information on adverse event reporting can be found in GHTF documents. To date, the Study Group 2 of the GHTF has provided documents on postmarket surveillance and vigilance issues. These documents named below are available from <http://www.ghtf.org/>. Please note that the documents are based on the regulatory requirements or practices existing in the participating countries, but that they are not identical to current regulatory requirements of individual countries. These documents represent a global model toward which existing systems should converge.

- SG2-N21R8: *Adverse Event Reporting Guidance for the Medical Device Manufacturer or Its Authorized Representative*
- SG2-N8R4: *Guidance on how to Handle Information Concerning Vigilance Reporting Related to Medical Devices*
- G2-N9R11: *Global Medical Devices Vigilance Report*
- SG2-N7R1: *Minimum Data Set for Manufacturer Reports to Competent Authority*

- SG2-N6R2: *Comparison of the Device Adverse Reporting Systems in the USA, Europe, Canada, Australia & Japan*

Please refer to: <http://www.ghtf.org/> for updated information.

Postmarket Surveillance and Vigilance in Developing Countries

The importance of the role of CEs and BMETs in device vigilance is particularly important in developing countries. The formal postmarket regulatory requirements can be implemented only if a country has medical device regulations. Most developing countries, however, have not yet established effective medical device regulations and enforcement. Furthermore, additional problems are facing developing countries, such as the following:

- A large amount of donated, second-hand equipment is still being used, which is unlikely to have distribution records from vendors. (See Chapter 43.) Thus, any device alerts will have difficulty reaching the users.
- Local vendor representatives of medical devices are often not technically knowledgeable. Relying upon manufacturers to send technical personnel to investigate a medical device incident can result in a long wait.

Developing countries are home to approximately two-thirds of the world's population. The deployment of medical devices in developing countries is increasing at a rapid rate, and considerations on the safety and performance of medical devices with regard to global public health must include these countries. However, there is a general shortage of technical personnel who are familiar with medical device matters; the potential contributions to post-market surveillance and vigilance from CEs and BMETs in developing countries are important resources that should be cultivated and utilized.

Conclusions

At present, the role of CEs and BMETs in postmarket surveillance and vigilance has not been openly designated by regulatory authorities and the GHTF. CEs and BMETs should develop the professionalism discussed in this chapter because they are in unique positions to co-operate with governments and manufacturers in adverse event monitoring, investigation, and reporting. Professional associations such as the International Federation of Medical and Biological Engineering (IFMBE) and the American College of Clinical Engineering (see Chapter 130) could promote this role to the national bodies that are concerned with patient-safety and medical device regulations. The author believes that this role should receive official recognition in the health care community for maximum utilization.

Medical device regulation is still a relatively young field and is constantly evolving. The Global Harmonization Task Force is playing a critical role in the harmonization of global regulatory requirements and procedures. The excellent work by GHTF members has made impressive progress in arriving at harmonized recommendations. The next stage of advancement for the GHTF should be to include the user as a representative on the task force.

So far, GHTF documents have focused on issues between industry and governments from industrialized countries. This situation might be a result of differing legislative mandates of founding member countries. The emphasis might be on product control. Because the actual use is the most critical stage in the life span of a medical device, it is desirable to include the user in the process of deciding matters associated with medical devices. The CE and BMET are strong candidates to represent an important user input to the GHTF in developing further recommendations for the medical device community. One important consequence of including user input from developing countries will be to make the work of the GHTF more inclusive on a global scale.

Small Business Development: Business Plan Development Fundamentals for the Entrepreneur

Peter W. Dyro

Principal, Re-Source Builders
Seattle, WA

Tristan Tzara once wrote, “Words are only postage stamps delivering the object for you to unwrap.” Similarly, the written business plan is a construct of diligence, a derivative of hundreds of hours of blood, sweat, and tears. Research, phone calls, sleepless nights, early mornings, analysis and re-analysis—the business plan becomes your best friend and your worst enemy. It is essential to keep in mind that the written business plan is not the business. The business plan is a medium for communication, merely a reflection of your dedication and strategy. It is a large part of your representation when you finally stand in front of the potential investor to whom you will sell your idea.

The business plan is an interface between you and your investors; it is the evidence of your thorough research. Investors will know in an instant the difference between a plan stuffed with filler and a well-researched operation. As this chapter will stress, focus on the logistics of the business, the market, the economics, the product, the risks, and constant analysis of the industry. A successful business plan will follow.

Your business plan should be subject to constant revision. In today’s Internet age, technologies and industries no longer evolve but see drastic turnovers in the way business is done. It has been said that the plan is obsolete at the printer; some would argue that it is obsolete before it even gets there! If one were to look at the business practices of new ventures today, none of them would match what was specified in the plan a year ago. Suffice it to say that your business plan is forever a work in progress.

To begin, the fundamental components of a business plan should include every aspect of your young venture. The document should be as lean as possible, containing only the essential information in the text. Necessary appendices may be added to the rear and referenced appropriately. The plan should be appealing and must not overwhelm the reader with technical lingo. Too much jargon could contribute to the ambiguity of the plan. One must be able to explain in common language the principal functions of the operation, the economics of the business, and the main idea without hiding behind fancy terms in order to remain vague and camouflage your lack of detail with rhetoric. Say what you want to say, and include genuine content. Do not make unsubstantiated claims such as estimating sales on the basis of what your company would like to produce. These claims will be sniffed out and will leave you high and dry as your would-be investor passes you over for a more truthful, realistic candidate.

Plan Format

The physical plan should follow the general format that is familiar to venture capitalists. Uniform formatting of the business plan will aid in establishing your credibility as a worthy candidate for capital. The following format was developed by two colleagues at the Venture Founders Corporation and is based on a over 20 years of observing entrepreneurs as well as actually preparing hundreds of plans (Timmons, 1999). This is not to say that the guidelines must be followed to the letter, because there are no absolutes in preparing a business plan. Every young venture is different, and some of the aspects of that venture could require a different take on the suggested outline.

Cover

The cover of your business plan should include all pertinent information about your new business, including name, address, contact information, date, and, most importantly, a statement of confidentiality. You must note that the document has been submitted on a confidential basis and is to be returned to the specified address should an investor not agree to accept the offering.

Executive Summary

The executive summary is usually the first substantial bit of text your investors will read, thus it should not be boring or wordy. Rather, it should describe the product or service and why it will be better than its closest competitor. Investors use the executive summary to weed out the definite “nos,” so it must be convincing. You will present your description of the business concept and how exactly your company will go about delivering on your promises. Include any information that will substantiate any claims to breakthrough technology, unique capabilities, or trade secrets that will provide you with a significant competitive advantage.

Summarize the opportunity and describe your strategy. Give a brief description of the market and the way you plan to approach it. Describe your competition, and list any of their weaknesses on which you can capitalize. Paint a picture of unfulfilled need by describing the shortcomings of the current industry. Be sure to note your plans for growth, and give concrete examples of the size of your market. Is your market growing? If not, what are you doing to create a market? From the size of your market and your positioning strategy, you should be able to project unit sales and expected revenues. Also include your pricing strategy and anticipated market share.

The investors interested in your company will be most interested in the economic details, so give your best estimate of timeframes until break-even and positive cash flow. Also give any key financial projections. Briefly describe your contribution analysis and the underlying operation and cash-conversion cycle.

The investor will also be interested in the composure of the team in which he is putting his money. Therefore, do not be modest. This is your opportunity to shine. Summarize any relevant experience you have that will contribute to this particular venture. Include key attributes from every member of the management team in order to portray a well-rounded experience pool. Note previous accomplishments, specific know-how, and people- and business-management skills, including sizes of divisions and projects.

You should conclude the executive summary with your offering. State the simple math: You invest this much, here's what you get. State the amount of capital you are looking for, and what portion of the company you are willing to surrender for that capital. You might want to include a simple breakdown of how the funding will be spent so as to clarify where all of the capital will be going.

The Industry, the Company, and its Products and/or Services

In this section of your plan, you will delve more deeply into the specifics of the industry and provide more detailed information on your product or service. This is your opportunity to tell investors why your company and product are great, and why they will do well in the market.

Present investors with an industry profile but make it concise as possible. Key points you will want to cover include industry structure and where in that structure the opportunity lies. Also discuss industry trends, overall growth of the industry, market size, and sustainability. Be sure to mention any new developments in the industry, such as new technologies that have revolutionized products or services, as well as manufacturing practices that enable more cost-effective production. What are the entry barriers? Why is everyone not starting a business in this industry?

Explain your business concept. Where in the industry are you positioning yourself as a company? You must have one (or more than one) target market. Describe your customers and what you are going to sell them. The investor also will want to know about the company's history, so include the date the business was created and the progress you have made to date. If your company has been in existence for several years, you will be liable for an explanation as to why you have not yet turned a profit, what you have learned, how your experiences have tempered your organization, and the steps you have taken to prevent future setbacks.

Next, describe the product in detail, provide a technical description, and emphasize any unique features that will carry the product to success in its market. Depending upon the product's stage of development, include either photographs or drawings and carefully describe the costs involved in development and testing.

It is important to list all of the uses of the product, including secondary uses. Is there any particular aspect of the product that equips it with a competitive advantage? If not, how are you going to beat the competition's price?

Coping with obsolescence is a major concern in today's market. It is important that you describe exactly what it is about your product that will keep you from being replaced. Will your product line be able to grow with technology or will technology grow around your product line? You must explain in depth what technologies you are incorporating in the design and production process. Give a very brief history of the technology if it is not common knowledge as well as any trends or new developments this technology has experienced. State the life expectancy of these technologies and your current plan for sustainability when the market catches up.

Define your entry strategy. What is your strategy for introducing the product or service to the market? There are four primary strategies to entering a market. One can enter with guns a-blazin', investing huge amounts of capital in a high-risk, potentially super-profitable venture. Such was the case with Hoffman La-Roche, a Swiss Pharmaceutical company that was marginal until it decided to invest all it had (and all it could borrow) to buy the patents for vitamins, hire the best discovers at unheard-of salaries, and manufacture and market over-the-counter vitamins for the first time, with astounding success. This all-or-nothing strategy capitalizes on being the first and the best in your market.

The second strategy capitalizes on leveraging on the ideas of others, taking a good idea and making it better, or finding a better use for it. Akio Morita of Sony flew to the United States after reading about the invention of the transistor by Bell Labs and bought a license to the transistor for \$25,000. Five years later, the Japanese were the sole providers of radios to the world.

The third strategy seeks to gain a monopoly over a certain market niche. While this strategy offers limited growth dependent on its host industry, it offers shelter from competition for the same reasons. Alcon realized a niche when it invented an enzyme that quickly became an integral part of cataract surgery worldwide. As momentous as the discovery was, the market for this enzyme totaled \$50 million per year worldwide, which was plenty for Alcon, but not enough to motivate competitors.

The fourth strategy creates a customer for itself, not by inventing a new product but by changing the utility, value, or economic characteristics of existing products. It capitalizes on creating a way to equip consumers with a good or service to which they would not otherwise have access. In the 1840s, Cyrus McCormick was one of many American who invented a harvesting machine. The American farmer, for whose benefit the machine was created, did not have the economic means to pay for it all at once, and banks were not willing to provide loans on such a new machine. All of the machines failed in the market, with the exception of Cyrus's machine, simply because Cyrus saw the need for installment buying and instituted it in his young company (Drucker, 1985).

Market Research and Analysis

This is the most crucial step in preparing the business plan. Your marketing research and analysis will lay the foundation for your entire plan, form your strategy, and determine resource requirements. Therefore, this step should be completed before all others. Research is essential for substantiating projected sales volumes and market size as well as finding out whether this product is something that your intended customer will actually buy.

Describe your customers. What is the economic and social reality of your target market? By accurately defining your customers, you begin honing in on your marketing strategy. Part of the research should focus on past industry trends. Examine what similar companies have done and what the outcome was. Use supporting facts and statistics to outline your marketing strategy. Consumer science can be a difficult and tedious process. You must examine socioeconomic trends, political developments, and demographic changes in order to determine what marketing strategy to use.

Compare your product to that of the competitors. What weaknesses leave them vulnerable? Are you capitalizing on those weaknesses? Also state the strengths of the competitors. Briefly demonstrate why companies have dropped out of the industry in past years, and how you will prevent it from happening to your company. Examine the four “Ps” of marketing: Product, price, place, and promotion. How are you doing in each arena? (Kotler, 1999) How are the competitors doing in each arena? Explain why customers will leave the competition for you.

As part of your market research, you should determine the value added by the product, who already has a similar product, and who will buy your product anyway. Identify every major customer group, and note the size of each. Based on the industry trends and your assessment of the advantages of your product over others, interpolate unit sales over the next three years. Be sure to show all assumptions.

A good marketing plan is forever a work in progress. Changing environments call for changing strategy. You must include how you plan to continually evaluate your marketing opportunities while improving your product, expanding your product line, adjusting your pricing, or entering new markets.

The Economics of the Business

Get out your finance textbook; this is your opportunity to impress the investor with some hard numbers. Show your gross margins and operating margins; your profit potential both before and after tax; and your fixed, variable, and semi-variable costs. Once you have laid out your entry plan, you should be able to estimate how much money you will spend, your costs, and your revenue from this. Give a timeline of your break-even analysis and explain any assumptions made. Also provide a timeline depicting when your company will run out of cash and when you will attain a positive cash flow.

Marketing Plan

Describe the marketing philosophy that you will use to accompany the entry strategy that you specified in the product section of the business plan. List the distribution channels

that you will use, and support your decisions with sound reasons. Also specify geographic range; your range should not exceed that of your market research. Indicate whether you will sell nationally, internationally, or globally. Indicate the types of customers to whom your product will be sold and what that product will mean to them. What will be the main selling point of the product? Specify whether it will be the low price, the additional quality, the warranty the service, or something else.

In this section, you must include a comprehensive discussion of why you priced the product the way you did. You must discuss price in terms of cost to manufacture: How will it effect your break-even time, your gross margin, and your operating margin? Discuss price in terms of competition. If you plan to undersell your competition, how will you maintain profitability while providing value to the customer? Discuss price in relation to customer payback. Will the value provided to the customer save him or her money in the long run? Show how long it will take for the product to pay for itself. Discuss pricing in terms of market share. Decide whether you are better off making \$100 dollars from each one and selling a million of them, or making \$75 dollars from each one and selling 3 million of them.

Describe the sales tactics you will use. Explain the distribution process and how you will attain the proper channels. You must describe how you will select sales representatives and the way they will position the product for sale. Illustrate the breakdown of the selling costs and present a sales budget that includes all marketing promotion and service costs.

Service and warranty may be used as a major selling point for your product. Explain in depth the warranty or service program to be offered. Indicate how much it will cost the company to maintain the service and warranty policy. Compare your service or warranty to that of your competitors.

Describe the types of advertising that you will administer if your product is aimed at consumers and trade shows and professional organization participation if you are selling to industry. Include a schedule for the release of your ads or tradeshow appearances. Also give a detailed description of the costs of such events.

Research your distribution channels and devise a sensitivity analysis to show how sensitive your business will be to changes in distribution cost. If your product requires any special care in the shipping process, make a note of it and explain how you will accommodate that need.

Design and Development Plans

Explain exactly where the product lies in the development phase. Give a brief report on capital already invested in the product, and explain how much more you need in order to bring the product to market. Also include the time frame in which you plan to have certain steps completed. Give yourself plenty of time, as most new ventures underestimate the amount of time needed to complete the product.

List difficulties that you have faced in the past, and any difficulties you anticipate. Describe the risks facing your project. Are all of the technologies there to complete the product? Is your product dependent on a nonexistent technology? If so, how do you plan to cope with development issues?

Your business will not last without constant improvement and innovation. How will the product improvement coincide with company growth? Will you be able to keep up the R&D cycle while turning a profit? Explain how you will finance the cost of R&D. If you have not achieved a positive cash flow by the time new development costs begin to pile up, where will you get the money? Explain how your future plans for the product line relate to the sustainability of the company.

This is also the section of the business plan in which ownership of the patent should be discussed. Will you share a patent with anyone, or does your company have exclusive rights? How much time do you have until your patent expires? Will your company have enough of a head start to get their "foot in the door" before other companies catch on?

Manufacturing and Operations Plans

This is the section of the plan where you will list the requirements for the geography, facility type, operating cycle, manufacturing process, and legal issues concerning the production of the actual product. The logistics of operation begin with choosing a suitable location. Carefully consider proximity to resources as well as proximity to customers.

If you are operating from an existing facility, describe the facility in depth, including plant, storage, office space, accessibility, and equipment. If you are starting from scratch, describe exactly what equipment you will need for start-up and how much it will cost. Do not plan to buy everything at once! Rather, set a schedule for obtaining overhead as it is needed. Prepare a three-year time line for equipment and facility acquisition.

Your explanation of the operating cycle should include the lead and lag time that are specific to the type of manufacturing you will be doing. Discuss your inventory system and its role in coping with any seasonal fluctuations you may anticipate.

Your manufacture process should be explained in detail, including the numbers of workers and managers required to operate the plant, cost of labor, and necessary skills needed to operate the machinery. Discuss the possibility of outsourcing some of the manufacture or assembly process. Also discuss the implications of economies of scale, buying in bulk, and potential suppliers.

The legal implications of firing up a manufacturing plant can be extensive. Note any federal, state, or local (e.g., zoning) laws that pertain to you as a manufacturer. Note all costs of obtaining necessary licenses and permits as well as any political activity that could affect your organization in the near future.

Management Team

The organization of the management team must be arranged according to the need of the particular business. Your young venture most likely will find the basic functional structure

to be the most efficient. Functional structures are most effective when one product line is being manufactured, which is often the case with fledgling corporations. This structure usually includes a president who oversees R&D, manufacturing, accounting, and marketing departments. Subsequent developments upon further growth of the business and its product line may warrant evolution of the organizational tree into a matrix or divisional structure. These structures allow for product-intensive management of the business (Daft, 2000).

List the key management personnel and their relevant skills and experiences as outlined in the executive summary. Include not only resumes of the principal management players, but also an in-depth analysis of their management performance. This analysis will help to determine their value to the company, which will translate directly to monetary form, as should be indicated in this section of the plan. List the salaries to be paid and the amount of equity to be given to each. Run the salaries of the management team against salaries earned at their last jobs, to show any contrasts and to emphasize dedication.

Investors will want to know with whom they are dealing, including other investors. List anyone who has invested in the company and what type of equity they own. List any employment agreements being negotiated and their corresponding compensation packages. Describe your plan for the board of directors. Indicate the ideal size and the representation you would like on the board. Also list any board members you have already chosen, along with a brief description of why.

Your young company may find it necessary to outsource much of the legal, consulting, advertising, marketing research, banking, or accounting. Be sure to include those whom you have chosen for these tasks, and why.

Overall Schedule

Prepare a realistic schedule for the completion of every task that is critical to the success of your venture. Do this by carefully listing all of the steps and then prioritizing them and assigning them to certain members of the team, along with due dates for each. Then lay the steps out on a time line and mark the most crucial points in the development of your venture. This will enable you to better visualize the crucial points and the necessary progress to reach those points. Discuss any weakness that you see in the time line. Point out any potential delays, and discuss how they will affect chain-reaction delays.

Critical Risks, Problems, and Assumptions

Starting your own small business is heavily laden with risk and uncertainty. One must think objectively and must address all sources of uncertainty, as well as any assumptions being made. This is your opportunity to identify all of the weak points in your business proposal and to explain what you will do to negotiate success. It also serves as an excellent opportunity to prove to the investor that you have thought of everything, carefully calculating your risks and not making any rash decisions. Explain your reasoning for making any decisions that may seem to compromise the success of the venture.

Investors must see that the management team is capable of identifying the risks and that it is honest in portraying them to the concerned parties. Do not try to hide risks or assumptions! A poor decision here will damage your credentials and will void any chance of funding.

Financial Plan

This section of the plan will include actual financial exhibits. If your plan involves an existing company, include actual income statements and balance sheets from the past two years to the present.

Construct *pro forma* income statements, balance sheets, and cash-flow analysis. Use your marketing research, your knowledge of the industry and seasonal trends to derive sales forecasts, production costs, and operating costs. Note all assumptions! Be sure to support your numbers with sound reasoning. Remember that every number you include in your plan is subject to the scrutiny and interrogation of the investor; make the numbers appealing, but be honest!

Building upon the information contained in your overall schedule, construct a break-even chart accompanied by a discussion of break-even sales volumes and price sensitivity (Scott et al., 1998).

Proposed Company Offering

This section summarizes the whole deal. Using your cash-flow projections, decide how much capital you are asking for, and devise a schedule demonstrating when and how it will be used.

Explain the stock offering, type of securities, and any nondistribution agreements by which they must abide, and how many shares of common stock will remain authorized, but unissued, after the initial offering.

Don't be vague! Indicate exactly how the investor will walk away from this venture with his compensation. Identify the exit mechanism, whether it is by IPO, sale, or merger.

Appendixes

Include any helpful material that is too lengthy or detailed to be placed in the body of the report. This may include technical drawings or descriptions, copies of permits or licenses, technical papers, research material, industry information, photographs, charts, and graphs.

The Next Step

Once you have all of the necessary parts and numbers, it is time to review. No matter how good you think you are, have another party look at it. Check for inconsistencies and feasibility. An outside perspective could save you thousands in costly mistakes. Finally, have the revised plan reviewed by an attorney in order that he or she may fine tune the language used and clarify any ambiguities. Now that your plan is complete, go forth and succeed!

Engineering Primary Health Care: The Sickle Cell Business Case

Yancy Y. Phillips

The Southeast Permanente Medical Group
Atlanta, GA

Thomas M. Judd

Director, Quality Assessment, Improvement and Reporting
Kaiser Permanente Georgia Region
Atlanta, GA

Within Kaiser Permanente's (KP) Southern California operations, the West Los Angeles (LA) Medical Center's Sickle Cell Medical Program, a national model for comprehensive and culturally sensitive pediatric and adult sickle cell treatment, was the 2001 winner of KP's national James A. Vohs Award for Quality. The program resulted in a drop of 22% in West LA emergency room (ER) visits from 1998 to 1999, compared to a 1% decrease among non-West LA ER sickle cell patients. Similarly, West LA hospital-bed days were reduced by 26% while non-West LA hospital utilization increased by 37% for the same patient population.

This chapter describes how this award-winning, "best-practice" program can be replicated in KP Georgia. It is an example of clinical engineering at the large health care systems level in which methods and processes are engineered to improve health care delivery significantly.

Sickle cell disease (SCD) is significant, affecting historically perhaps an underserved portion of the KP membership, African-Americans, and a newly emerging portion, Hispanic-Americans. Proper SCD management meets several KP Georgia cross-cutting quality improvement themes, such as continuity and coordination of care, integration of primary and specialty care, and community interest in minority health issues. SCD presents an opportunity to improve the quality of life for members with SCD while incorporating service and affordability goals. Therefore, SCD management meets our key business goal of first in quality, first in service, and first in affordability.

SCD was designated by KP Georgia's Quality Forum a health management system (HMS) in December 2001. HMS components to be developed include: evidence-based practitioner clinical practice guidelines; key people resources and roles for physician champion, project manager, and care manager, as well as clear roles for primary care practitioners (PCPs), specialty care practitioners (SCPs), and community resources; education for practitioners, staff, patient, and family members, and patient self-management techniques; data systems, including registry, population risk stratification, and ability to monitor health outcomes; and process improvements led by an implementation team for streamlined care and systems' interventions.

Main expected results are reduced hospitalization, reduced ER visits, and improved quality of life (QOL) to be demonstrated by patient, nursing, and practitioner surveys.

The program will enhance continuity of care by clearly defining the PCP's role and closing the gap on patients who are not firmly anchored to their PCPs. It will be shown how SCD care should be coordinated with PCPs, SCPs, and community resources.

Sickle Cell Business Case

The objective of the sickle cell disease (SCD) health management system (HMS) program is to improve health care outcomes for KP Georgia members who have SCD, and to improve care options for their caregivers and their TSPMG (The Southeast Permanente Medical Group, Inc.) and affiliated practitioners through health education, enhanced self-efficacy, and the effective use of resources.

Market

The market for the SCD program are KP Georgia members with diagnosed SCD, TSPMG practitioners, and the KP Georgia health care delivery system. Program stakeholders are members; families and caregivers; pediatric, adult, and hematology practitioners; and the KP Georgia health care delivery system.

As of April 2002, KP Georgia provided care for 252 children and adults with SCD, or 0.04% of the membership. There were 138 members under 17 years of age and 114 members over 17 years of age. There were 149 females and 103 males. There was an approximately 25% growth in members with SCD from 1997–2001, while overall KP Georgia membership grew by about 10% during this time.

Financial Implications

SCD medical expenses per member per month (pmpm) are 2.7 times greater for adults, and 7 times greater for the pediatric population. Total pmpm of care for SCD members increased 35% from 1997–2001, an average of 8% annually. Total in-patient pmpm for SCD members increased 60% from 1997–2001, an average of 12% annually. The number of emergency room (ER) visits was 173 in 2000, and 231 in 2001, at approximately \$500 per visit.

Current KP Georgia HMS programs for chronic diseases include asthma, diabetes, cardiovascular disease (CHF/CAD), and depression. All HMS programs have a primary care physician champion and are managed within the TSPMG PCP health care team (PCP-HCT) medical model.

While KP Georgia does not directly control the hospitals, current PCP-HCT patient-management practice does affect hospital admissions for chronic diseases. Current PCP-HCT patient management, within the context of active HMS disease processes, can reduce treatment delays, especially when an exacerbation of a disease process occurs, decreasing ER visits, hospital stays, and hospital costs, and increasing member satisfaction.

Goals

The program goals are to give members, families, and caregivers the following:

- Self-empowerment, self-efficacy, and shared decision making
- Increased PCP bonding, leading to improved clinical outcomes and quality of life
- Member and patient education classes and educational materials, including telephonic and web-based, designed for SCD and patterned after other HMS programs.
- Health promotion and prevention information and resources in both regular and after hours settings to provide “anticipatory guidance.”
- Improved practitioner efficacy and member self-efficacy through use of care management resources

The goals for physicians and health care practitioners are increased TSPMG practitioners’ knowledge of, and comfort in, treating patients with SCD, including:

- SCD chronic disease management processes
- Written, telephonic, or web-based educational material and resources
- National, KP Georgia, and community SCD and chronic disease resources

Outcomes

The anticipated outcomes of the SCD program are improved continuity and coordination of care (CCC) for members with SCD. This continuity and coordination of care will result in improved access to needed services as measured by the number of PCPs who attended to an SCD patient with greater than three primary care encounters in a given year. Research has shown that a PCP provides best overall CCC for chronic-disease patients with multiple annual visits. Another result will be appropriate and early treatment when acute and chronic complications arise, with improved integration between primary and specialty care, resulting in decreased ER visits and fewer hospital admissions, decreased average length of stay (ALOS), and overall decreased inpatient costs.

Other outcomes include no decrease (and probably an increase) in PCP and SCP visits and improved patient and practitioner satisfaction, increasing success of short-term and long-term SCD treatment and management.

Several KP Georgia Barriers

The SCD program must consider the following elements that could adversely affect the success of the program:

- The lack of PCP experience and efficacy to identify and treat SCD patients, because they refer to hematologists
- The need to identify SCD patients for purposes of population-based care management, to address preventive issues and systems issues, such as co-pay waivers for same-day visits to different practitioners for SCD
- The inability to readily control hospital admissions and costs, as is done by KP hospital-based regions
- Unique community resources that are not incorporated into care plan management
- The lack of practitioner knowledge about adult and pediatric SCD differences
- Inadequate specialty care relationships and feedback systems
- The lack of SCD-specific pain medication guidelines

SCD Program Description

Management and Key Roles

SCD Physician Champion

The program must have a physician champion. Such an individual is necessary to carry out the following responsibilities:

- Serving as the leader-facilitator for disease content authority
- Serving as the leader-facilitator for SCD awareness in primary care throughout KP Georgia
- Serving as the leader-facilitator for guideline development, review, renewal, and implementation
- Serving as the leader-facilitator in determining and implementing SCD measurement outcomes
- Serving as the national and local representative for TSPMG on SCD-related committees, task forces, and conventions

In the start-up and following year, this position would be 0.2 FTE, in keeping with other HMS programs. It will allow the SCD champion to give three disease-oriented, continuing medical education (CME) lectures to KP Georgia PCPs during the first year of the SCD program, then yearly to twice-yearly updates regarding SCD education, care, and management.

SCD RN Care Manager

Patterned after the West LA program, the SCD program will employ a 1.0 FTE RN care manager, who will provide a comprehensive “wrap around” service delivery to

SCD members; an additional 0.2 FTE for case management and care-management assistance will be provided by Quantitative Risk Management (QRM) to ensure continuous coverage. The care manager will also work with the SCD Work Group, SCD champion, HMS Steering Committee, HMS Implementation Committee, and Quality Forum to identify ongoing delivery system modification needs and to help facilitate system changes.

Other responsibilities of the SCD RN care manager include the following:

- Ensuring that patients have regular appointments with a hematologist and their PCP to improve treatment plan compliance
- Providing educational counseling for the newly diagnosed patients on disease history, current treatments, primary care needs, and the care delivery system
- Educating patients and their families regarding the importance of following self care and home care plans to avoid complications
- Educating patients and their families regarding inappropriate ER use
- Providing patients and their families with information regarding health care resources and referrals within KP Georgia and the community at large; being knowledgeable about insurance coverage and the benefit structure for SCD patients
- Establishing and maintaining good rapport with patients and their families by being aware of their health care issues (e.g., making frequent follow-up calls, directing them to support groups, and making home visits)
- Serving as a contact person for subspecialist consultants, TSPMG practitioners, advice nurses and call center requests; include ability for Care Manager “book” same-day appointment with PCP for patient in crisis
- Collaborating with community agencies to promote information sharing, KP’s community involvement, staying abreast of upcoming programs and events and developing resources
- Assisting in the facilitation of a smooth transition from a pediatric to an adult SCD patient to ensure continuity of care
- Participating in national and regional educational conferences; providing educational presentations to school and day-care nurses, staff, teachers, and administrators to help promote awareness of SCD
- Ensuring that pediatric SCD patients have a treatment plan on file at their school, which may include an individualized education plan, modified physical activity, and/or special consideration regarding classrooms’ proximity
- Partnering and assisting SCD physician champion in arranging educational in-services for KP Georgia staff
- Being responsible for maintaining a disease registry and being aware of the progress of hospitalized SCD patients and their potential discharge dates, and acting as a referral source and point of contact for feedback with case managers in QRM Department
- Ensuring appropriate follow-up after acute care, hospitalization, or ER visits, using available next-day information about previous care
- Developing and implementing with Pharmacy an efficient prescription refill process (e.g., for antibiotics and pain medication).

SCD Program Manager

As in all KP Georgia health management system programs, there will be a 0.5 FTE program manager for SCD. The RN care manager will report to the SCD project manager, who will report to the director of population-based care (PBC). Responsibilities of the SCD program manager include:

- Facilitating the SCD Work Group, reporting to HMS Steering and Implementation Committees and the Quality Forum
- Overseeing development of all needed HMS components (i.e., guidelines, personnel, patient and practitioner and staff education, data systems, communications, and documentation of program interventions and outcomes) as appropriate

Other Resources Needed

Patient Registry, Tracking, and Follow-Up

At present, there is an informal registry of 252 members; a more formalized database will need to be developed. KP Georgia utilizes the pharmacy-based and web-based POINT Computerized Clinical Tracking System for several applications. POINT is used in KP Southern California and includes an automatic field for SCD data. Its web-based feature allows more flexibility in its access by practitioners and staff. Until it is implemented, KP Georgia will explore the use of the computerized clinical system that is currently used for dermatology and breast health tracking.

Tracking criteria include all patients who meet the designated SCD diagnostic codes. Clinical indicators to be tracked for each patient include at least childhood and influenza immunization history as well as other SCD items in POINT, such as pharmacy refills. Linkage of this tracking capability to the data warehouse will allow next-day follow-up related to TSPMG primary or specialty care or ambulatory health care (AHC) visits, as there is nightly download of this information from the KP CADENCE appointment system.

Sub-Specialty Care

Subspecialty care is essential for the care of SCD patients, due to a variety of factors. While related complications are relatively common in SCD patients, the management of complications frequently involves interventions that are uniquely targeted to SCD patients and that are gleaned only from a working knowledge of the SCD literature.

For pediatric patients, virtually 100% of the subspecialty care access will be directed through the Pediatric Hematologist at Children’s Health care of Atlanta (CHOA) Scottish Rite Hospital. PCPs will rarely initiate subspecialty access; essentially, the pediatric hematologist is the co-gatekeeper.

For adult patients, the PCP will assume a much more central role in the subspecialty care access. All patients will see the adult hematologist two or four times per year. The adult PCPs will direct care to the subspecialty care physician based on practice guidelines or on the recommendation of the adult hematologist, other subspecialists, or the SCD physician champion.

Occasionally, adult SCD patients will be referred to the SCD program at Grady Hospital for development of a care plan. These referrals will be based on established criteria. Examples might include an SCD patient who has recalcitrant leg ulcers or chronic pain (not acute pain) that is unresponsive to a conventional outpatient protocol. Fewer than 10% of the adult patients are expected to need this type of referral.

Community Resources

The SCD Foundation of Georgia might be a resource for the families of children with SCD, for additional education as well as participation in Camp New Hope and other childhood SCD-related programs. The Sickle Cell Disease Association of America web site also provides key related information: <http://sicklecelldisease.org/>

The CHOA Pediatric Hematology SCD nurse practitioner and social worker will be resources, as well. At times, individualized education plans, homebound teaching, or modification of physical education or school classes will be needed, and they will be instituted through a joint effort of the KP Georgia SCD RN care manager and the CHOA pediatric hematology SCD nurse practitioner and social worker.

The schools need to be included in the SCD management team. The PCP and pediatric hematologist and the SCD RN care manager will develop treatment plans that all pediatric SCD patients will have on file at their schools.

The KP social worker will be available for adult patients who need help managing job-related issues that relate to having a chronic disease.

QRM Case Management

The care management of members with SCD will be a collaborative effort between the QRM and PBC departments. The role of the QRM case manager will be to partner with the SCD RN care manager to facilitate care coordination across the continuum, particularly to focus on hospitalized patients and to provide back-up care coordination when the care manager is not available.

Recommended Implementation Tasks and Timetable

At program initiation, the SCD champion will be named, and the SCD RN care manager and SCD project manager will be hired. The SCD champion will develop clinical practice guidelines in partnership with chiefs of medicine and pediatrics and KP Georgia population-based care department and will be in place and approved within six months after initiation. The CME schedule will be developed with the practitioners for months seven through nine. The SCD care manager will have an office at Gwinnett Medical Office, near the SCD physician champion, for the first six months, to facilitate rapid program development and a clear understanding of clinical issues involved.

The SCD RN care manager's next steps will be the following:

- Establishing contact with adult and pediatrics SCD subspecialists (e.g., hematology and pulmonology); ensuring that all patients on SCD registry have a PCP and hematologist; and meeting with relevant case managers, benefits representatives, pharmacy managers, social workers, and CHOA nurse practitioners
- Visiting Grady Hospital's SCD clinic and doing follow-up with Sickle Cell Foundation
- Creating SCD Program brochure; making educational and reference folders for newly diagnosed patients, school and childcare facilities, and new KP members; and preparing educational materials for teaching health care teams about SCD
- Compiling resource lists for the following services:

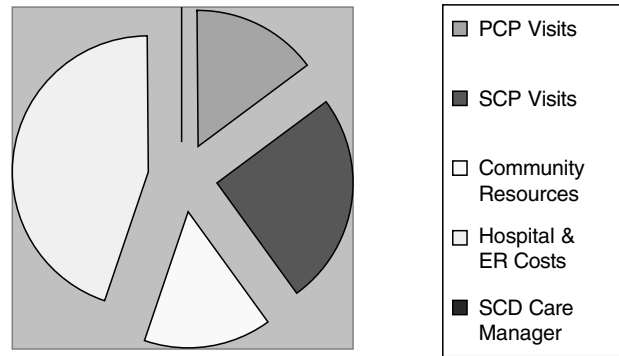

Genetic counseling	Support groups (parents, teens, and adults)	Stress management
Pain management	Proper nutrition-appropriate exercise	Tutorial services
Stroke prevention	Depression screening	Infection prevention
Smoking cessation		Forms: Self care, pain

- Developing a formal program development plan and overseeing its implementation, to meet established goals and the timetable set by Clinical Affairs and the SCD Work Group

Conclusions

The SCD HMS Program will increase health care options for SCD members, their families, and their primary and specialty care practitioners through health education, self-

Current SCD Management

Future SCD Management

Figure 141-1 Expected differences in personnel, outcomes, and resource use between the current situation for SCD management in KP Georgia and the proposed SCD-management program.

efficacy, and the effective use of resources on the part of members and practitioners. By adopting this program, KP Georgia will realize a decrease in total health care costs and an increase in perceived quality of service and quality of care outcomes.

Projected hospital savings in the program's third year are \$124,000 for pediatrics and \$135,000 for adults; 30% and 40%, respectively. Projected ER savings in 2005 are \$34,000 for pediatrics and \$27,000 for adults, a 40% savings. There is a net \$158,000 program savings in year three. Four-year net present value (NPV) for the program is \$85,000.

Improved satisfaction and quality of life are to be demonstrated by surveys, using the West LA tools. Quality of care relating to continuity and coordination of care will be improved access to one's own PCP to direct appropriate services, resulting in decreased ER visits, hospital admissions, and ALOS. No decrease (or increase) in PCP and SCP visits is expected. Other SCD clinical management process and outcomes measures will be determined.

The KP Georgia health care delivery system will realize greater effectiveness and efficiency in service provision. This could impact not only SCD HMS members, but other HMS registry members, as well. This can occur as we overcome the barriers cited and provide solutions to our delivery system's continuity and coordination of care challenges.

In summary, Figure 141-1 shows the expected differences in personnel, outcomes, and resource use between the current situation for SCD management in KP Georgia and the proposed SCD-management program.

Care Facilities SOTERA
Research Institute for Health
Hut, Finland

As citizens of the world look ahead to the future, their expectations for health care should be viewed first from the standpoint of demands placed on health care systems.

The population of planet Earth grew to one billion by 1804. Then, 123 years later (1927), the population reached two billion; 33 years later (1960) three billion; 14 years later (1974) four billion; 13 years later (1987) five billion; and 12 years later (1999) six billion. Population is growing at an ever-increasing rate (Lewis, 2000). Recent projections show that the world population is estimated to be 8.9 billion in 2050, even though birth rates have fallen in many countries. Most of the gain will occur in the developing world, where countries are already overpopulated. Roughly 10 billion inhabitants in the latter half of the 21st century will have to cope with outstripping natural resources of the Earth.

Jonathan C. Lewis, Academy of International Health Studies, California USA, pointed out: “[Six] billion people are now living on Village Earth. With me, imagine shrinking this multitude to just 100 people, all living together in a small village. One tiny village has 58 Asians, 13 Africans, 10 Latin Americans, 8 Europeans and 6 North Americans, 51 Villagers are female; 49 are male. Half the Village is under 25 years of age. The men live on average 61 years. The women live 3 years longer. Our village is a Tower of Babel, 20 villagers speak Chinese, 8 Speak English, 7 converse in Hindi, 6 in Spanish, 5 in Russian, 4 in Bengali, another 4 in Arabic, 3 in Portuguese, and 2 each communicate in Japanese, French and German. 30 villagers are Christians, 70 are not. 37 have jobs. 18 are illiterate and 1 has a college education. 80 live in substandard housing. 50 villagers are malnourished and do not have access to basic sanitary toilet. 96 people share 50% of the village’s health care resources. The 20 poorest villagers consume just one and a half percent of all goods and services; the 20 richest villagers eat 45% of the meat and fish, use 59% of energy, 84% of all paper and own 87% of all vehicles. 5 people control 50% of the village’s total wealth, and those 5 individuals live in a special neighbourhood called the United States. Village Earth is the world in which we live and the world in which health care must be delivered and financed (Lewis, 2000).”

Demands on health care systems will be partly influenced by diseases that arise from malnutrition. Populations in both India and China have already exceeded over one billion, and 53% of Indian children are malnourished. The observation of the Worldwatch Institute that half of the world population was starving in the year 2000 and 1.2 billion people had no access to clean water suggests that simple preventive measures can reduce strains on future health care systems. Health care expenditures of the world population, per capita, differ in large scale from U.S.\$20 to \$3700 in a year. The world health care system varies across populations. For example, about 70% of the world population does not benefit from the use of X-rays, although this technology is more than 100 years old. Medical education varies, and the delivery systems differ. One could easily believe that the situation will be the same after 50 more years. Conversely, equitable opportunities for economic development, peace and prosperity, inter-area, access to quality and affordable health care may not be critical issues. As the World Health Organization (WHO) recently redefined issues of human health to have physical, mental, social and spiritual aspects, the future may be associated with a societal commitment to improving the general well-being of all inhabitants of planet Earth. Appropriate provision of health care, medical care, and welfare services to all is important and must be sustained (Nagasawa, 1992). The major challenge is in knowing how to achieve this goal.

The challenge of making educated guesses as to what the situation will be in 2050 is demanding. On the other hand, those who will be in their 70s in 2050 are all living today. They have our genes, and they will suffer the current diseases: Infections in developing areas, and cancer and cardiovascular problems in the Western world. To develop a new

medicine takes at least 10 years; to test it clinically takes 5–7 years; and to have it accepted by regulatory agencies and practitioners takes 5–7 years. The total process can take 10–20 years. The life cycle of hospital equipment can be between 10 and 25 years. On the other hand, the medical system is conservative and slow to change. Most of today’s hospitals will work at the same site, but the building will be refurbished. Many treatments are changed, but slowly new devices may make procedures easier, and more effective pharmaceuticals may shorten treatment time dramatically. Thus, as the authors present their visions, the reader may have some disagreement. Nevertheless, the reader must place such directions in the abstract and must think imaginatively. To permit such thinking, detailed discussion of future diseases is left out because it would be beyond the scope of this handbook.

This chapter focuses on the global view in health care planning and architecture, both in developing and developed countries, on the basis of WHO documents and the authors’ experiences as consultants to authorities in developing regions in Asia and in Baltic region. Additionally, experience is included from the current project of Global University Programs in Healthcare Architecture (GUPHA), an international organization linking and promoting educational and research programs of 11 technical universities in health care architecture (primarily aiming at projecting the scope of health care architecture in the year 2050) is included.

Factors influencing the prediction of development health care architecture can be grouped into three categories as follows: (1) country and culture; (2) provision of services that are critical to the delivery of care; and (3) environment of activities. Each of these factors is interrelated; if separated, they will almost certainly result in deficiencies of design or operation. Even if these deficiencies are overcome, social acceptance might be lacking.

Country and Culture

These criteria can include the scales of north/south, east/west, old/new, and developed/developing. Ten categories to consider are as follows:

1. Population (e.g., total number and age/sex structure)
2. Land area (e.g., natural border and man-made border)
3. Population density (e.g., rural/urban and major cities)
4. Climate (e.g., temperature, humidity, rainfall, constant wind, monsoon, savannah, and frigid areas)
5. Terrain (e.g., mountain, plane, forest, island, and earthquake-affected)
6. Demography (e.g., birth / death rate, population growth, infant mortality, life expectancy)
7. Epidemiological (e.g., infectious diseases and major cause of death)
8. Health financing (e.g., medical expenditure and budget, income/outcome)
9. Health provision system (e.g., insurance, network and health personnel)
10. Political/social situation (e.g., government, democratic, socialist, social classes, education, transportation and economy)

Global Population in 2050

At this time, there are several predictions available, all ending up with 9 billion people living on the globe in 2050. On the basis of analyzing world population growth in 2050, the distinction of four continents or geographic areas can be seen. Among the countries

that will fully utilize high-tech, western medical technologies, the United States will increase its population in 50 years to about 400 million, while European countries and Japan will decrease their populations. The main increase of population will take place in the regions near the equator (e.g., Africa, India, and Brazil). The aging population, especially over 80 years old and mainly female, will grow all over the world, but particularly rapidly in Asia.

Healthy Environment

According to the Agenda 21 statement from the UNCED (1992) Rio de Janeiro environment summit, 60% of the Earth's population will live in cities in the year 2050. The critical issues facing these populations and their governing bodies are numerous and include the following: Water/air quality and pollution; nutrition and food supplies; congestion of communication and transportation systems; energy resources and consumption; noise, stress, and access to open spaces and recreation areas; responsive education, social, and criminal justice systems; sufficient employment and housing opportunities; and brutal commercial and residential development. Without proper intervention, the daily news will discuss the ecocatastrophe of the greenhouse effect, the rise of sea level, and perhaps unremitting air pollution. Looking more carefully at the data, one finds that the sea level 20,000 year ago was 124 meters below the current level. The increase during the last century was 15 cm. The expectation is that sea level will increase 50 cm from the 1900 level by 2100. The increase could have an effect on societies located along the deltas of large rivers, such as the Ganges, Nile, or Mississippi. Some of the islands in the Caribbean and in Polynesia are having difficulty because of storms, and they may disappear. This may require fast mobile health care teams. The catastrophes, as difficult as they might be for an individual, might not affect the increased world population.

Beyond natural catastrophes are epidemic diseases, such as HIV, which produce dramatic effects south of the equator in Africa or in large cities in Eastern Europe. Of equal magnitude are new strains of tuberculosis that are resistant to modern drug regimens and that could turn into large, worldwide epidemics as larger numbers of the world's citizens travel the globe. Although the WHO and the United Nations are currently developing standards for treatment and consensus statements on such problems, a more uniform acknowledgement of their authorities should take place. Universal funding of worldwide problems would strengthen defense against the health care problems of the world.

Man-made air pollution will increase the incidence of lung diseases and will continue to cause serious problems to individuals. On the other hand, many people who live together with smokers will suffer, but with a relatively long life expectancy. There are many reports available from London, rural areas, and Tokyo demonstrating ways in which clean air has reduced health problems. We have to remember that the incidence of tuberculosis was reduced by improvement of urban sanitation systems well before effective treatment with curative drugs. These famous, well-documented success stories indicate the importance of a healthy environment also in the future. To plan healthy, urban environments in a future metropolis is perhaps the most effective tool in preventive medicine.

Funding of Services

The status of the economy in a geographical area will be dominant in the next 50 years. In most countries, resources in health care will be limited to under 10% of GNP. The need to use medical technology will grow perhaps 15% annually, but the GNP will grow less than 4%. Governments would like to reduce health care costs even below the present levels. Resources will be the same or less than today's levels. However, the societies are aging, so each elderly person will have fewer resources to use. The pressure on health care providers for more economical solutions is increasing, thus necessitating that priorities be set, and services optimized. Beyond developed health care systems, the economic problems of the Third World are critical. The gap between affluence and poverty is easily understood when one considers that health care in many African countries is based mainly on donations today that might not be available in the future. The focus in developing countries will be on preventive measures such as providing adequate nutrition, clean water and air, and immunization against diseases that have been eliminated in developed countries. Such measures are inexpensive when compared to measures that are intended to cure disease. On this optimistic note, we must be mindful that the diseases of developed countries could become health care nemeses as cultures advance in affluence. When health care funding is limited to U.S. \$30–100 per person per year, clean air and water represent the most effective use of money for developing countries. Future research must focus on preventing diseases such as cancer and heart disease, which plague developed countries today.

Provision of Services

Variety of Health Care

These criteria may include the range of activities from a human's birth to death, health promotion/prevention/care/cure/rehabilitation, and if only 10 items were to be considered, the following would illustrate the point:

1. Health promotion (e.g., health education and physical fitness)
2. Family planning (e.g., birth control and pre-/post-natal care)
3. Disease prevention (e.g., vaccination and daily life)
4. Primary care (e.g., general practitioners, doctor's offices, community health, and first aid)
5. Secondary acute care (e.g., hospital services)
6. Tertiary medical care (e.g., teaching hospitals and specialized hospitals)
7. Rehabilitation (e.g., physical and stroke)
8. Accident/emergency treatment
9. Care for special-needs populations (e.g., handicapped and elderly, mentally deficient)
10. Terminal care (i.e., hospice care)

Trends in Health Care

Regardless of the technology, therapeutic intervention, or preventive measure utilized in improving the health of the world population, history demonstrates that the most sophisticated health care delivered by the sub-specialist in the most highly specialized institution becomes common place within 10–20 years. For example, the treatment of hypertension in the United States in the 1950s was provided by only the most knowledgeable researchers. By the 1970s, these researchers focused their efforts on the education of the primary care physician on the benefits of treatment of hypertension. By the dawn of the millennium, the worldwide treatment of hypertension had become the responsibility of the primary care physician. The dilution therapy of cardiac infarction today is often started in primary care units or in ambulances. Similar comments could be made about the diagnosis and treatment of asthma. We can expect that technology, therapeutic interventions, and preventive measures will diffuse in a similar way from the developed countries to those developing their economic profiles. Although one may take a pessimistic view, there is a hint of better things to come as developing countries benefit from the lessons of the well-to-do countries as they strive to improve the economics of health care. This concept also can be extended in the expectation that the technology in the tertiary health care center today will become the technology of the primary health care center of tomorrow. As one attempts to define the physical architecture of the hospital of the future, we must keep in mind that as the world grows smaller, communication improves and becomes more universal. In a sense, communications, architecture, diagnostic technologies, and therapeutic interventions begin to define the concept of global hospital 2050. To understand this statement, the following areas should be examined:

- Improved imaging technologies
- Improved diagnostic methods
- Improved surgical interventions
- Genetic and immunological therapies
- Improved preventive measures
- Reduced burdens of individual responsibility for the cost of care

Imaging Technology

At the present time, there is no doubt that imaging technologies have become more sensitive and specific. This trend can be seen easily when high-resolution CT images of the thorax are utilized in the diagnosis of inflammatory lung diseases or PET scans are utilized to image solitary pulmonary nodules. The former technique has made it possible to examine noninvasively the anatomy of the inflamed lung, and the latter to determine the presence of cancer. Magnetic resonance imaging (MRI) technology has advanced to the point where vascular imaging is now possible. Again, noninvasive methodology prevails. The operative theme is clearly a trend toward noninvasive diagnostic imaging. Over time, one could expect that these imaging technologies will become more portable and available in locations far beyond the walls of the traditional hospital. Access will become more universal. With respect to imaging modalities, the hospital of the future may become the command post from which images are ordered and analyzed. Improved communication networks will make it possible for the isolated practitioner to be connected to the most sophisticated medical centers. In the same sense that health care networks are developed today, the network of the future will de-emphasize physical facility and will emphasize communication and diffusion of technology to disparate locations.

Improved Diagnostic Methods

Improved imaging technology will make it possible for visualization of diseased organs and tissues by noninvasive techniques. The presence of cancer can be determined by such methods without tissue sampling. This trend will lend further credibility to minimally invasive surgery. For the future, one might project that laboratory studies done only in central laboratories can be performed in peripheral sites through the development of intelligent sensors that might relay abnormalities in blood detected by noninvasive methods to central processors. By the same token, one might foresee that tertiary health care facilities could become command posts from which medical care is directed. Technology will become more portable and smaller, to the point where diagnostic laboratories will be widespread and freely accessible. In one sense, this will reduce demands on central laboratories, but it could increase burdens on health care centers as requests for therapeutic intervention could increase. Improved imaging and diagnostic methods will be combined. Direct visualization of various organs and tissues by fiberoptic instruments will permit diagnosis of abnormal tissue without necessity for tissue biopsies. This will reduce demands for central laboratory services but may again increase demands for therapeutic services.

Improved Surgical Techniques

The future of surgical techniques is already being defined by the development of minimally invasive surgical centers. Within such centers, the disciplines of radiology, anesthesia, surgery, and medicine interact and use combined services. Imaging modalities appear in operating rooms. Radiologists may perform certain procedures that were performed only by surgeons in the past. Surgeons may utilize instruments that allow visualization of organs or cavities of the body and surgery on them through small incisions. Tissue damage during surgery is lessened, wound healing is hastened, and recovery time is shortened. In the future, utilization of acute care hospitals will be by patients with higher acuity. Recovery and rehabilitation will be accomplished in sites peripheral to the hospital and in the home.

Beyond the trend in minimally invasive surgery, there is expectation that some surgical procedures will be performed by robots directed by surgeons in remote locations. The possibility of a global hospital system based on imaging and real-time visualization will require mature communication systems. The architecture of the hospital of the future may be based on communication architecture. Again, demands for large centralized hospitals will lessen as technology becomes more portable and access to health care more widely distributed.

Current techniques in transplantation of solid organs such as lungs, hearts, and kidneys may change with the expectation that these organs will be obtained from laboratories rather than harvested from human donors. Stem cells could be programmed to generate new organs. Alternatively, these cells could be introduced into the body through infusion, with proper genetic programming, to replace diseased or damaged tissue or organs. Laboratories could be necessary to support organ development or maintain stem cells.

Genetic and Immunological Therapies

The Human Genome Project has made it possible for researchers to better understand the molecular basis of diseases such as asthma, inflammatory bowel disease, arthritis, and, to a certain extent, coronary artery disease. Therapeutic modalities are now directed at events occurring at the molecular and genetic levels. As the pathophysiology of disease is understood, the genetic predisposition to such disease can be determined. Thus, preventive medicine will be based on improving environment and eliminating some stresses that cause disease. Prevention will be based not only upon cleaning our environment but also upon identifying those individuals who should avoid additional environmental stresses.

Our current knowledge of the treatment of infectious diseases is based on prevention, immunization, and treatment with microbial agents if prevention and immunization fail. As medical science learns more about the human body's host defense mechanisms, treatment of infectious diseases can be based on the enhancement of host defense rather than with antimicrobial agents.

Improved Preventive Measures

The concept of a global hospital for 2050 implies that technology and the ability to apply medical knowledge will be universally distributed. The diseases that plague developed countries today will be better controlled and, perhaps, eliminated. At the beginning of the 21st century, such countries are already experiencing a reduction in deaths from coronary artery disease, but these same countries are plagued with infectious diseases (such as tuberculosis), not because treatment is not available, but because of reservoirs of infection created by immigrant populations and others infected with the human immunodeficiency virus (HIV). In the future, these same diseases will be controlled not because of the measures instituted in the developed countries, but rather by the efforts of these countries to help developing countries to treat and eliminate these diseases. In the natural evolution of countries and economies, developing countries will benefit from the lessons learned from developed countries that have conquered diseases that burden their health care systems. Economies of scale will be realized. Future generations will enjoy the benefits of better diets and maintenance of good physical condition. According to the Organization for Economic Cooperation and Development (OECD) health statistics, the life expectancy over the last 30 years has increased an average of 2–3 years for both males and females in most countries. This trend will continue, and healthy life will be longer, and the portion of inactive life before death will be a smaller percentage of the total life.

Reduced Burdens of Individual Responsibility for the Cost of Care

As the 21st century enters its infancy, the citizens of the world have developed a keen sense of responsibility in caring for themselves collectively. What is good for one also must be good for the majority, and vice versa. By the same token, each individual citizen should contribute to the good of the group. In the past, there has often been social

upheaval because of discrepancy in the distribution of wealth and resources. As the world's health improves, so will its economy. Hopefully, this evolution will also create equitable distribution of health care facilities and reduction in the cost of care to the point where it no longer will be necessary for the individual to assume total responsibility for the cost of medical care. The concept of welfare will be replaced with community care.

Community care as a responsibility will develop as the number of people in the world over 80 years of age increases to about 400 million by 2050 (see Figure 142-1). When one considers that 50% of these individuals will live in Asia, it is not surprising that implementation of community care has started in Japan and that interest has intensified in China. Alternatives to acute-care-hospital delivery of medical care will be realized in the home, group homes, and nursing homes.

Medical Cultures

The Utopia for which citizens of Planet Earth have searched since the dawn of intelligent life may exist only as an ideal. Attempts to materialize the concept are influenced by the culture of those who attempt its expression, and, in a sense, can be extrapolated to the concept of "Global Hospital 2050." The moral and cultural issues that influence the delivery of health care can be identified in the United States, Central Europe, the Nordic countries, Russian, and Japan. Each has different priorities. As global communication advances, and as storehouses of human knowledge become standardized with methods of cataloging and retrieving information, the benefits and shortcomings of techniques and therapies will be understood more universally. Such understanding will reduce cultural differences in the delivery of health care. For example, what is considered to be Chinese medicine today will be integrated into western medicine. Anecdotal medicine based on valid experience will become increasingly more evidenced-based in the future.

Problems are different in the Third World, where resources are limited by economic and technological constraints. Beyond these obvious facts, one also must consider that technological development takes place in a stepwise fashion. Initial heavy monetary investment in the form of capital and manpower gives way to economic implementation and cost-effective utilization. Through all of these steps, medical personnel become educated as to methods that will affect the most cost-effective and satisfactory outcomes. What is known as state-of-the-art technology or medical practice today in developed countries could become the basis for best practices in 2050 in countries that are considered to be the Third World today. This seems to be a logical progression such that the time may come when worldwide communication and dissemination of knowledge will eliminate what we know as the Third World.

By 2050, we could see technology dividing itself into two cultures—one of developed countries, and one of developing countries. The former would be based on communication networks linking imaging technology, laboratory information, and tasks performed by robots in laboratories, operating and recovery rooms, and intensive care units. Wireless technology will reduce the expenses of hardware connection of devices. For the latter, labor costs could be relatively inexpensive, and economic development in what we know today as the Third World could be possible by making health care in and of itself a component of each country's gross domestic product. In 2050, medical technology in these countries might be only at a 2001 level. However, as the communication networks of developed countries mature, they will reach worldwide acceptance, permitting linkages and dissemination of knowledge to the point where a universal health care system is available to all, regardless of the maturity of a country's economy.

Figure 142-1 World population 80 years and older, 1995–2050. (From Graeme Hugo, *Over to the Next Century: Continuities and Discontinuities*, <http://www.un.org/depts/escap/pop/apss141/chap8.htm>).

As communication improves and medical knowledge becomes more universal, global efforts to improve the health status of entire populations will increase. Hospitals will form co-operative nets over state boundaries, allowing medical knowledge and skill to diffuse worldwide. This trend will accelerate the development of universal practice patterns, technology development, and, perhaps, hospital and health care facility architecture.

Environment of Health Care Activities

The Variety of Environments

A wide spectrum of facilities to be used for health care invites analysis. These areas include the following:

- Tools (e.g., installation and equipment)
- Rooms (e.g., bed rooms and component)
- Houses (e.g., private houses, group homes and collective houses)
- Community facilities (e.g., shops, schools, offices, health-promotion centers, sports centers, fitness centers and community centers)
- Ambulatory facilities (e.g., clinics, group practice offices, health centers, diagnostic centers, day care centers, sheltered workshops and day surgeries)
- Halfway facilities (e.g., halfway houses, community hospitals, and rehabilitation centers)
- Acute-care centers (e.g., emergency centers, general hospitals, women's centers, children's hospitals, cancer centers, tertiary medical centers, circulatory disease centers, and critical care centers)
- Assisted livings (e.g., nursing homes and homes for the elderly)
- Terminal care facilities (e.g., hospices and cemeteries)
- Mobile hospitals (e.g., hospital ships, flying hospitals, and space ships)

With the above areas in focus, we can expect the functionality and quality of buildings to improve to fit the medical cultures of the areas in which they exist. Over time, there should be agreement on standardized environments and medical practice that will define physical architecture. The end result will be a higher quality of care for all.

Trends in the Design of the Acute Care Hospital

Trends in the design and utilization of acute care hospitals are beginning to suggest that large centralized facilities can become inefficient and costly. As various medical technologies have become more widely distributed, networks of smaller facilities have become more efficient and have created the concept of regionalization. It is this regionalization that will add a human element and will permit systems to be adapted more to the culture of areas or regions served.

The modern hospital began to grow up during the 1950s. New functional units, such as radiology departments, clinical laboratory units, central sterile supply departments, and medical record centers were technology-intensive and required centralization for economical reasons. A compact hospital block for 800–1200 patients was developed. During the 1960s, British authorities and the WHO recommended building three 1000-bed acute-care hospitals for each one million inhabitants in order to improve economic efficiency and to use professional resources fully. The development in building technologies allowed the development of broad buildings with artificial illumination, clean-air ventilation, and electrical heating/cooling systems. At the same time, natural sunlight, fresh open-air circulation, and optimum room temperature was lost. Additionally, the centralization of hospital functions created the various complicated traffic systems for people and material inside the building. Hospital staff and patients may walk long distances through various departments during the day and may wait in each one for prolonged periods of time for testing or for service. With such obvious shortcomings, hospital designers began to explore more compact building shapes in order to reduce cost by reducing external wall-to-floor ratios. The aim was to shorten walking distances among relevant departments. The result is that the modern hospital building looks more like a factory than a human environment. Patients who present to such institutions often feel separated from their emotional and physical support systems.

Complicating the impersonality of large health care institutions, the development in medical technology continues, and no limit can be seen. New procedures will continuously change the space requirement. New methods implemented by newly trained medical teams will require a compact department with inpatient wards, outpatient departments, and diagnostics rooms with possibilities for procedures. The supporting services will receive more attention. The central sterilization systems, storages, and material supplies for kitchens and departments will work more on industrial principles. Logistics and process control will increase; for example, requirements for change, in the 1990s Nordic acute care hospitals, 3%–5% of floor area within these hospitals was annually under refurbishment. With the expectation of continuous change, buildings in the future must be able to accommodate periodic economic reconfiguration without major structural change. Changing technology might require installations to be changed, perhaps in 8–12-year intervals. Refurbishment is expensive and will more so be in the future. The hospital communication net will be complex and needs special knowledge for planning flexibility and for maintenance of the software. For detection of hospital-acquired infections, new automatic-control technology alarming through the hospital communication system will control epidemics and will identify potential epidemics before they start. The trend is toward an intelligent building where basic technical networks allow fast and easy reinstallation of inside walls and the reinstallation of equipment. Beyond versatility in modification lies the requirement for smaller buildings that are more widely distributed with extensive communication systems creating more of a global concept of health care. Beyond versatility in modification lies the requirement for smaller buildings where the function is centralized to departments that do not carry labels of medical specialties. Rather, patients will be grouped on the basis of need, such as critical care and orthopedics. The units will be more widely distributed in the form of a village with extensive

communication systems to centralized departments, near or far, creating more of a global concept of health care.

The demands on health care facilities and environment vary. The hospitals to be used in 2050 in OECD countries already exist. New, effective, high-tech hospitals will be needed in the United States, where the population will increase. Similarly, in 2001, the British government announced a need for 100 new hospitals to meet the demand for medical service. Several new-model hospitals will be built in developing areas to be a model for local development. Conversely, in Europe and Japan, where populations are decreasing, few new hospitals will be built. By the same token, the absolute need of more health care services is characteristic of countries such as India, China, and Russia, where some 20,000 hospitals need refurbishment and enlargement to accommodate modern technology. At the lower end of the spectrum, provisions must be made for basic health care and environmental amenities such as food, potable water, and sanitary installations in the regions near the equator.

In this environment, hospital sites are stable, and managers have conceptual plans for future medical programs. Such programs call for modification and enlargement of existing buildings. Generally, strategic plans extend for 20–30 years, while a building's life expectancy is 30–50 years. Thus, architectural plans should allow for stability through two changes in strategic planning and two renovations and expansions.

Network of Smaller Scale Buildings

The compact hospital body with patient towers has remarkable difficulty in expanding its functions. Overall administrative costs in a large hospital complex are growing and difficult to control, but by the same token, the special care hospital functioning at a lower level works more efficiently but cannot implement all of the new methods. However, as knowledge bases become more widespread and communications networks improve, portable technology will make specialty centers more universally distributed. Such development will further strengthen the trend toward ambulatory care. The effect will be a global reduction in large, acute care facilities, a process now already well-known in Europe and the United States. In 2000, it started in China and it is expected to change the situation dramatically in Russian health care delivery.

The integration of medical and social services back to the society is foreseeable. Health care facilities will be placed where people will visit and stay with fewer physical and psychological (i.e., less institutional) barriers. The trend might well be toward a medical-mall concept. The basic elements are primary care units, hospitals, elderly care apartments, pharmacy, medical supplies, social service centers, club rooms, restaurants, shops, and music halls with cinemas. Individual clinics or service buildings also may form a hospital village where outside traffic lines are in parks or in Nordic areas with snow in a tunnel network. Some of the services may be far away but connected to the same communication net, as, for example, the term "X-ray images reading center" indicates. Administration of services provided to 3–5 million people through a network of 60–100 facilities would be managed by one organization. Such an organization might have an international profile joining hospitals in developing areas and permitting faster dissemination of technology and medical knowledge. This type of administration further strengthens the concept of Global Hospital 2050. The tendency in the modern service delivery system to bring services to the home may become more universally accepted as medical technology becomes more portable and information technology makes its application more feasible. Service network planning thus will be an important task for health care authorities.

More Human Design

Current health care buildings are not very conducive to human occupation. The environment is sterile. The accessibility to the institution is often problematic for a wheelchair user, and access to public transport is not universally available. The lighting is problematic for the visually impaired. The scale of the facility is too massive for human comfort. Patient rooms are based on programmatic needs. Surgical pavilions might be located at a great distance from emergency departments or intensive care units. Patient and personnel traffic patterns might not always be conducive to the best patient care. In the future, more human design is needed. The environment must be positive and healing. The natural and indirect lighting, human scale, landscaping, use of colors, and textiles are the tools of the designer. The trend is to analyze the functions in patient treatment and design space for processes. Individual rooms will decrease in numbers. Instead of individual rooms for procedures, the department will have the landscape space where large teams can work and equipment for several procedures can be stored.

Conclusions

Three aspects (country and culture, provision of services, and environment of activities) configure one cube (i.e., three-dimensional grid) representing our impressions of current health issues. The components of the cube will be developed according to the development of technology, improvement of education, and changes in social structure. For instance, the development of information technology will influence the availability of health services in less-developed areas. Societal consciousness of the global environment will increase awareness of what is necessary to make it more healthful. As this cube looks like the fortune-teller's crystal ball, we may call it the "crystal cube" through which the future is visualized.

Preventive methods, biomedical treatment methods, medical equipment technology and communication systems will continue to develop. No limits are in sight. Less-expensive technical solutions for developing countries are needed, and they are necessary to the implementation of new methods globally. This could open new possibilities for the health care technology industry. The growing functional and administrative networking of hospitals, the global tendency toward evidence-based medicine, and the implementation of quality systems will harmonize medical services globally. Perhaps in 2050 we can speak on Global Medicine in the Global Hospital. The facilities will be more human in design and will meet

health care needs regardless of the culture of its occupants. Finally, global efforts to improve the environment of Planet Earth may very well reduce demands for health care in general.

Generally, it is very difficult to forecast our future. Arthur C. Clarke wrote his book *Profiles of the Future* in 1958 and showed us a chronological timetable of the future until the year of 2100, together with one of the past, back to 1800. He forecast what would happen 40 years after 1960. He anticipated human emigration to other planets, artificial intelligence (AI), global libraries, wireless energy, ocean mines, and an extended feeling of time passing. In addition, he predicted several achievements by 2050 (e.g. gravity control, memory recorder, and human hibernation). Clarke limited his work to the fields of natural science and technology, but it is amazing to find his ideas to be more or less accurate and in accord with our current views. This reveals that the forecast of our future is not impossible.

There is a distinct difference between what will be and what should be, 50 years hence. Our impressions are that health care is not the responsibility of individual nations but rather a global responsibility to be shared by all, with all contributing to the best of their abilities. Developed countries must facilitate advancement of those less developed through universal endorsement of efforts of socially acceptable organizations. The efforts of the World Health Organization and the United Nations must be universally endorsed as pathways through which the health of our global population will advance. With the recognition of organizations that have global profiles, monetary and human resources can be prioritized and equitably distributed. Advances in communication technology will facilitate dissemination of medical knowledge. Finally, we should recognize that even today's medical technology made available to developing countries in 2050 will represent a major advancement in the delivery of health care. What is known as the "community hospital" in the Western world today could tomorrow improve the quality of life of those living in areas in central Africa, India, and South America. Speculation is endless, but the concept of universal health care is not.

Appendix 10-A: Sample Request for Proposal (rfp)

REQUEST FOR PROPOSAL

THIS IS A REQUEST FOR PROPOSAL TO PURCHASE AN 80-100 CHANNEL MEDICAL TELEMETRY SYSTEM

ISSUE DATE:

Preparer and Point of Contact: System Representative Clinical Engineer

Your Hospital, Bob's Lane. Anywhere, USA

TABLE OF CONTENTS

Introduction 1

Vendor Qualifications 2

- a) Vendor References
- b) Available Site Visits

Product Specifications

Vendor Presentation Schedule

Installation

Delivery Date & Payment Methods

Contract Submissions & Amendments

- A) Technical and Clinical Training
- B) Accessories
- C) Warranty
- D) Service After Warranty
- E) Miscellaneous

Final Contract and Closing Schedule

Today's Date

Your Hospital has one of the most dynamic cardiac programs in Central Texas. We require an expansion of our ECG telemetry capabilities. Your company is invited to bid on a proposed 80-100 channel, digital telemetry system. The product specifications are listed on page 4 and 5. *Bids will be accepted until close of business on August 30th, XXXX.* Delivery and installation must be completed by February 1st, XXXX.

Please direct all correspondence in this matter to:

Director, Clinical Engineering & Telecommunications
(Office) XXXXXXXX
(Fax) XXXXXXXX (e-mail) XXX@mail.yourhospital.org

PRODUCT SPECIFICATIONS

- 1) Product must operate in the UHF medical frequency band with digital transmission signal capabilities.
- 2) Open systems hardware – (nonproprietary)
- 3) Transmitters will be **water-resistant**.
- 4) Transmitters will operate on a standard AA or AAA battery.
- 5) Monitors will have color display
- 6) Product must conform to National Fire Protection Agency safety standards:
 - A) Chapter 3 – Electrical systems – all sections
 - B) Chapter 9-Manufacturer Requirements – all sections
 - i) See Chapter 2 – Patient-Care-Related Electrical Appliance
- 7) Product must conform to American National Standard Institute and Association for the Advancement of Medical Instrumentation Standards:
 - A) ES-1 1993 (Safe Current Limits for Electromedical Apparatus) – all sections
 - B) ES11 – 1991 (Diagnostic Electrographic Devices) – all sections
 - C) EC38 – 1994 (Ambulatory Electrocardiographs) – all sections
- 8) Product must operate in the UHF medical frequency band with digital transmission signal capabilities.
- 9) Open systems hardware – (nonproprietary)
- 10) Software license issued in accordance with hospital policy (see attachment B).
- 11) Transmitters will be **water-resistant**.
- 12) Transmitters will operate on a standard AA or AAA battery.
- 13) Monitors will have color display for 72 hour trending analysis and real-time alarms.
- 14) Analog signal ECG trace on monitors with corresponding digital values for heart rate.
- 15) ST segment analysis.

Our Company meets or exceeds the above required specifications

Signed _____

VENDOR QUALIFICATIONS

All bidding vendors must have product manufacturer experience in medical telemetry for at least five (5) years. All bidding vendors must have no unresolved FDA actions or pending FDA actions related to the Safe Medical Devices Act or the Good Manufacturing Practices act. Any company FDA incidents within the past five (5) years must be disclosed.

Our Company conforms to the above vendor qualifications

_____ (Signature) _____ (printed name) _____ (title)

List of any FDA related actions against your company in the past 5 years.

If none state: No FDA actions

Vendor References:

Provide a list of all sales of ECG telemetry, which your company has sold in the past 2 years that match the exact specifications required by SJRHC (e.g. same software revision, same hardware revision).

Vendor Site Visits:

Provide a list of available hospitals from the above vendor reference list located in Texas that would be available for a site visit.

INSTALLATION

The vendor must provide staff for the installation/application of the demonstrated product and the final installation of the purchased product. This will include antennae installation to allow coverage of the entire facility. Final installation will be completed by *February 1st, 2002*.

DELIVERY DATE & PAYMENT METHODS

The product will be delivered in coordination with the Clinical Engineering Department and the Purchasing/Materials Department in order to meet the February 1st,XXX installation date.

Contact for Final Negotiations:

Director, Purchasing/Materials Services Department

CONTRACT SUBMISSIONS & AMENDMENTS

The final contract will consider:

- A) Technical & Clinical Training
- B) Accessories
- C) Warranty
- D) Service After Warranty E) Miscellaneous

FINAL CONTRACT AND CLOSING SCHEDULE

The final contract must contain all information and inspections required on the checklist found on page X of this RFP.

Appendix 10-B Position Description

*CITY HOSPITAL
POSITION DESCRIPTION*

POSITION TITLE: Clinical Engineer

DEPARTMENT: Clinical engineering **CODE:**

Participates in the care of patients in the following age groups:

1 Neonate (0-1month) **1 Infant (1 month to 1 year)** **1 Toddler (1yr-3 yrs)**
1 Preschooler (3yr-6yr) **1 School Age (6yr-12yr)** **1 Adolescent (13yr-18yr)**
1 Early Adult (19yr-45yr) **1 Late Adult (45yr-64yr)** **1 Geriatric(65yr +)**

POSITION SUMMARY:

Performs a broad scope of duties under the general supervision of the Director Clinical Engineering. Provides sound leadership and management to assure services that include Clinical Engineering, Telecommunications, Engineering Internship and Cooperative Education Programs, technology assessment, and others are cost effective, efficient and highest quality so as to maintain the maximum standards for the customer. Performs a variety of leadership, technical and administrative tasks to support the Facility's Missions, Values, and Objectives. The employee in this position will be required to demonstrate competencies in providing service for the care of patients/customers between the age groups of neonate through geriatric.

EDUCATION AND EXPERIENCE:

Bachelor of Science in Engineering or Engineering Technology degree required. Preferential consideration for Certified Clinical Engineer (CCE) or obtain certification within one year after accepting position. At least three years of experience in Clinical Engineering or management activities in a Health Care environment. Fundamental understanding of schematics, repair diagrams, electronics, anatomy and physiology, telecommunications processing, medical equipment principles of operation, and related electronic test equipment. Technical knowledge and understanding of NFPA Codes, NEC Codes, Hospital Safety, Infection Control, and JCAHO Environment of Care standards. Has received training and/or is familiar with computer-based maintenance management systems, technology assessment matrixes, computer management spreadsheets, and computer graphics programs. Has the ability to prepare and coordinate lecture materials and present lectures and educational in-services relating to medical equipment and telecommunications. Has a general knowledge of Body Substance Isolation Techniques, using gloves, masks, and protective outerwear. Possesses the ability to establish and maintain effective working relationships with department staff, patients, visitors, and other hospital staff. Has the ability to effectively lead and manage a diversified staff providing equal opportunity for all to succeed with excellence.

Is willing to work additional hours other than those prescribed during a normal duty day in order to accomplish the tasks/jobs, assist in emergency situations, and or special events. Is willing to treat all people with dignity, courtesy, and fairness and promote the Hospital's values, missions, and philosophy, and objectives. Is able to pass a required physical examination and drug screening test.

PERFORMANCE STANDARDS:

Values

1. Exhibits willingness to understand, follow, and promote the hospital's mission, values, philosophy, and objectives.
2. Demonstrates ability to positively interact with persons of different ethnic, spiritual, moral and cultural beliefs.
3. Treats all people courteously, fairly, and with dignity.
4. Establishes, participates in, and fosters effective working relationships with our customers.
5. Ensures confidentiality of all customer information.
6. Uses, distributes, and conserves resources in consideration of the environment.
7. Willingness to support peers with their duties and responsibilities.

Safety

1. Shows willingness to read, understand, and follow all safety policies and procedures, according to organizational and departmental policies.
2. Performs essential work duties as identified in the attached Performance Evaluation Criteria.
3. Demonstrates proper body mechanics when performing tasks.
4. Utilizes standard precautions when performing tasks where contamination may be present.

Physical Requirements

1. Stands for long periods of time
2. Works in limited-space area
3. Carries, pushes/pulls, lifts up to 50 pounds

Mental Requirements

1. Understands and follows oral and written instructions/directions.
2. Organizes, prioritizes, and/or completes workload within designated time.
3. Communicates potential problems according to departmental and organizational policies.
4. Recognizes and responds to age specific needs of population served.
5. Participates in quality improvement activities-assesses, measures, improves.

Department Director

Human Resources

Date

**CITY HOSPITAL
PERFORMANCE EVALUATION CRITERIA**

POSITION: Clinical Engineer
Review Date: _____

TYPICAL DUTIES AND RESPONSIBILITIES

	STANDARD					
	Importance	Time	Weighted Value	Rating 1-5	Score	Comments
<p>Policy development and enforcement Provides policy development and review related to medical equipment and the environment of care. Ensures new procedures are understood by all co-workers and enforced. Relates policies to mission and vision statements and practical applications of core values: Service, Reverence, and Stewardship</p>	3	4	7			
<p>Management of financial & personnel resources Supervises Clinical Engineering and Telecommunications Dept. personnel and facilitates department meetings. Reviews and coordinates schedules. Works as a team member and provides proactive solutions to scheduling conflicts. Maintains schedule with less than 3% overtime. Maintains operating budget with less than 5% budget variance overall in both departments. Completes personnel performance reviews within 10 working days of due date.</p>	8	5	13			
<p>Communication Provides nursing, physician and technical in-services on topics related to equipment operation and maintenance to improve the quality of care. Develops and reviews training objectives in conjunction with Director, Education Services to achieve Process Improvement where indicated. Coordinates and enhances relationships with Texas A&M University and other community organizations.</p>	2	2	4			
<p>Safety and legal oversight Demonstrates knowledge of hospital procedures for fire, severe weather, bomb threat, local disasters, and patient distress calls. Facilitates safety and values seminars as required in hospital policy, mission and vision statements. Identifies SMDA related incidents and completes proper documentation. Has no more than 1 deficiency per year in this area as a performance standard. Maintains a 90% injury-free work environment. Serves as a member of the Hospital Safety Committee and Medical Equipment Management and Standards Subcommittee. Attends 90% of safety as a performance standard.</p>	5	7	12			
<p>Special Projects Completes all assignments delegated by the VP Support Services in a timely manner.</p>	4	6	10			
<p>Construction and Renovation Attends weekly project meetings and reports concerns to VP Support Services. Ensures most cost-effective approach is taken and budget for projects is within projected cost. Reviews plans to insure federal and state health and safety codes are met.</p>	6	8	14			
<p>Personal and professional growth Continues education either through correspondence or traditional classroom courses related to clinical engineering with the goal of earning a master's degree. Participates in local and national organizations related to clinical engineering.</p>	1	1	2			
<p>Technology Assessment Provides system leadership and demonstrates technology assessment expertise in matters related to medical equipment acquisition and service contracts. Assists the VP Support Services and ORT in recommendations for equipment acquisition.</p>	7	3	10

- Clinical data, 12, 31, 115, 125, 241, 367, 456-460, 463, 487, 587
- Clinical Engineering (CE)
 Budgeting, 1, 5, 8, 10, 17, 21, 24, 27, 29, 31-32, 35-39, 49-50, 55-56, 59, 62, 65-68, 71-73, 75, 78, 85, 88, 93, 96, 102-104, 107-108, 111-112, 124, 136, 149-150, 152-153, 160, 170, 172-173, 177, 182, 188-195, 199, 201, 216, 228, 248, 298, 302-303, 306, 308-309, 318, 331, 343, 350, 360, 383, 451-452, 486, 524-527, 532, 575, 604, 606, 614, 626, 632, 646-647
- Certification, 3, 6-7, 9, 15-16, 41-42, 46, 49, 51, 54, 59-60, 68, 71, 77, 80, 82, 86, 91-92, 116, 212, 227, 236, 271, 279-280, 291, 301-302, 304, 307-308, 310, 320, 328, 332, 334, 349, 383, 394, 408, 498, 507, 549, 558, 574, 577, 593, 596-598, 601-603, 606-610, 613, 617-620
- Compensation, 43, 46, 198, 206-207, 210, 212, 216, 291, 302, 313, 356, 388, 390, 590
- Consulting, 2, 6, 12-13, 19-20, 22, 25, 27, 29-33, 35-39, 41-44, 48-51, 53, 55-56, 62, 67-68, 71-75, 82, 87, 97, 114, 116, 119, 152, 160, 162, 170, 177, 188-190, 192-195, 199, 211, 214, 218, 225, 227, 252, 263-264, 266-267, 269-270, 274, 282, 297, 299, 309, 320, 323, 328, 341, 348, 356, 368-369, 374, 412, 426, 431, 433, 460, 466, 485, 501, 506, 526-527, 530, 559, 567, 576, 578, 588, 592, 597, 604, 610, 617, 619, 625-626, 644-645, 648
- Definition, 3, 5-7, 17, 36, 56, 61, 92, 94, 102-103, 122, 170, 179, 184, 188, 196, 203, 211, 216, 224, 235, 244, 248, 298, 343, 346, 349, 356, 360, 364, 385, 395, 417, 422, 436, 456, 494, 497, 503, 513, 521, 527-528, 544, 549, 557, 576-577, 593, 595, 597-601, 607, 609, 618, 621, 627, 644-645
- Department, 3-6, 16-19, 22, 26, 28, 36-41, 49, 53, 58-63, 80-82, 84, 86, 90-92, 97-98, 103-104, 107, 111, 119, 125-129, 143-144, 147-149, 151-153, 172, 179, 182, 188-199, 201-203, 205-207, 211-212, 227, 237, 239, 244, 249, 264, 267, 270, 277, 285, 294, 297-298, 306, 311, 313, 315-316, 324-325, 327, 343, 347, 350, 354, 370-371, 378, 383-384, 400, 421, 431, 433, 435, 441-443, 456, 460, 462-463, 497, 543, 551, 559, 568, 570, 575-576, 590, 609-610, 613, 615, 644, 646-647
- Education, 1-3, 7, 16, 18-20, 22, 24-25, 27, 33, 39, 41-42, 46, 49, 51, 53, 55-56, 59, 61-62, 66-68, 72, 74, 77, 80-82, 86, 88-89, 91-92, 94, 98, 103, 124, 148, 160, 174, 202, 207, 214, 216, 222, 227, 238, 242-244, 248, 268-271, 278-279, 285, 290-291, 294-295, 297, 299, 301, 304, 306, 308-312, 314-318, 321-325, 327, 329, 332-335, 343, 346-349, 354, 371, 435, 463, 485, 496-497, 500, 504-505, 511-512, 525-527, 530, 532, 544, 550, 568-569, 572, 575, 577, 592-593, 595, 597-598, 601-603, 605-606, 608-609, 612-614, 617-619, 623, 625-626, 644-646, 652, 654, 656, 658
- Function, 18, 24, 59, 92, 107, 199, 201, 385, 614, 624
- International, 7, 12-13, 15, 18, 33, 42, 51, 53, 58, 61, 64, 66, 71-74, 77, 80, 82-83, 85, 89, 91-92, 97-98, 110, 116, 118, 124, 134, 155-156, 158, 164, 168, 170, 172-173, 175, 179, 182, 199, 205, 218, 222, 225, 235, 262, 280-281, 285, 295, 301-302, 304-307, 310, 313, 315, 329, 332, 334-335, 343, 345, 358, 426, 443, 454, 498, 520, 532, 538, 542, 546, 555, 557-560, 564, 568, 578, 580, 593, 600-603, 605, 607-608, 613, 617, 619, 645, 648, 658
- Management, 1-7, 10, 12-17, 19-24, 26-39, 41-42, 44-46, 48-51, 53, 55-56, 58-68, 71-72, 74-75, 77-80, 82, 84-94, 97-98, 102-104, 107-108, 110-114, 118-119, 122, 124-130, 132, 134-138, 140-143, 146-147, 149-153, 155-156, 158-160, 162, 164, 166, 168, 170-177, 179, 182-183, 188-189, 191-193, 195, 197-207, 210-214, 216, 218-220, 222, 224-225, 227, 232, 234-240, 242-245, 249-250, 252, 262, 267, 269-271, 280, 285, 287, 289-291, 294-295, 297-298, 300-302, 304-309, 311-312, 315, 317-318, 320, 322-335, 337, 341, 344, 346-347, 349, 352-355, 362, 369-371, 374, 378, 383-386, 400, 408, 411, 421, 431-433, 435-436, 449-452, 454, 456, 458, 460, 462-463, 474, 480, 485-486, 495-497, 500-501, 504-505, 507-508, 510-511, 518, 520-521, 525-528, 530-532, 538, 540, 546, 548-552, 555, 557-560, 566-569, 572-578, 580, 588, 590, 592-593, 596-599, 601-603, 605-608, 610, 612, 616, 618, 621, 623-628, 644-647, 650, 652, 654
- Policies & procedures, 1, 5, 24, 45, 88, 124, 135, 170, 203, 236, 238, 240, 242-244, 264, 269-270, 325, 327, 353, 485, 500-505, 511, 521, 528, 530, 551, 572, 577, 606
- Productivity, 200-201, 205
- Profession, 1-2, 6-7, 10, 12-15, 19, 23-24, 35-39, 49, 51, 53, 58-59, 61-62, 64-65, 71, 82, 179, 199-200, 212, 237, 245, 282, 285, 290-291, 304, 307, 312-315, 318, 320, 322, 327, 341, 350, 370-371, 449, 456, 462, 520, 576-578, 593, 595-603, 606-608, 610-612, 617-619, 621, 624, 646
- Service providers, 9, 20, 27, 56, 63, 67, 119, 124-126, 129, 136, 140, 143-144, 147-149, 151-152, 154, 191-192, 236, 269, 328, 346-347, 566-567, 574-575, 593, 614
- Space allocation, 51, 55-57
- Staff requirements, 66, 206, 574

- Staff productivity, 55, 96
 Staffing levels (see also Staff requirements), 41, 55, 63, 173, 186, 206, 628

 Inventory, 4-5, 8-9, 17, 29, 36, 44-45, 51, 59, 62, 67-68, 74, 78-80, 104, 107-111, 122-124, 126-127, 134-135, 147, 151, 153, 164, 183, 190, 207, 211, 223, 235-236, 239, 252, 282, 300, 321, 328, 339-340, 347-348, 350-351, 383, 400, 431-432, 496-497, 505, 507-508, 535, 551-552, 572, 574-575, 577, 625, 645
 Maintenance, 4, 7-10, 12, 15, 17, 20-21, 26, 28-31, 36-38, 41, 44, 49, 59-63, 66-68, 71-72, 74-75, 78-80, 82-83, 91-92, 99, 104, 107-112, 122-124, 126-127, 130-132, 134-135, 137, 142, 147-153, 155-158, 160-162, 165-166, 169-170, 173, 179, 189-191, 202, 207, 209, 211, 221, 223, 228-229, 237-240, 245-247, 249, 252, 267-272, 274, 277, 282, 291, 294-295, 297-301, 304, 312, 315, 318, 322-323, 328, 333, 339, 342-344, 346-347, 353-354, 356, 359, 368, 376, 378, 383, 412, 421, 423-424, 426, 431-437, 442, 451, 453, 459, 462, 495-497, 505, 520, 525, 533, 542-543, 545, 558, 567-568, 572, 574-575, 577, 579, 581, 583-584, 590, 598-599, 601, 606, 610, 618-619, 625-626, 644, 648
 Manufacturers, 3, 5, 7-10, 15, 17, 20-21, 23, 28, 31, 38, 41-47, 59-60, 66-68, 79, 91, 107, 109, 111, 115, 118, 123-124, 126-127, 130, 132, 135, 137, 147-152, 156, 158, 171, 173, 207, 221-222, 225, 227-228, 235-240, 247, 250-251, 257, 259-261, 263-264, 267, 269-274, 277, 280, 282, 291, 294-295, 301-302, 312-313, 315, 321, 324-325, 337, 342, 344, 346-349, 353-354, 356-357, 366-370, 400, 412-413, 415, 420, 426, 431-437, 443, 450, 453, 485, 491-495, 497, 507, 509-510, 542-543, 552, 555, 557-558, 567, 573-575, 578-586, 588-592, 599, 610, 619, 625-626, 638, 647-648
 Users, 3, 9, 15, 20-21, 26, 30, 33, 37-38, 45, 47, 49, 60, 62, 66-68, 75, 80, 82-83, 99, 104, 107-109, 111-112, 115, 118, 122-124, 126-127, 131-132, 135, 137, 141, 147-153, 155-156, 158, 161-164, 166, 170, 173, 183, 189, 191, 202, 207, 211, 223, 236, 238, 249, 252, 255, 260-261, 263, 272, 274, 277, 280-281, 298, 312-313, 315-316, 321-325, 327, 342-343, 346-349, 351, 353-357, 359, 364-371, 376, 378, 383, 410, 421, 426, 431, 434-435, 437, 439, 446, 449, 451, 453, 459-460, 462, 485, 491-497, 505, 510, 533, 552, 559, 572, 574-575, 577, 579-587, 589, 591-592, 606, 619, 621, 623, 625-626, 638, 644-645, 647-648
 Manufacturing, 10, 20, 37, 107-108, 147-148, 150, 160, 185, 222, 235, 272, 328, 330, 337, 346, 348-349, 356, 359, 434-435, 557, 567, 580, 583, 586-589, 610, 644-645
 Operators, 15, 40, 67, 78, 80, 109, 111, 124, 148, 155-156, 158, 225, 246-247, 249, 257, 268-269, 271-272, 277, 279, 281, 312, 315, 324, 355, 367, 370-371, 431-432, 434, 436-437, 439, 446, 491, 510, 533, 535, 567, 592, 648
 Purchasing, 4-5, 9-10, 20-21, 23, 26, 29-30, 36, 38, 42, 44, 59, 62-63, 65-68, 71, 80, 82-83, 91, 104, 107, 109-112, 115, 118, 124, 126-127, 135, 141, 147-153, 155, 158, 160, 164, 166, 171, 173, 189, 193, 221, 236-238, 261, 264, 272, 282, 300, 302, 323, 342, 344, 346-347, 353, 356, 366-368, 371, 383, 413, 416, 421, 424, 426, 431-432, 435, 451, 496, 507, 525-526, 551-552, 564, 575, 583, 591, 599, 624
 Recalls, 20-21, 23, 47, 62, 79, 107, 124, 126, 147, 155-156, 221, 223, 236-237, 239, 272, 274, 316, 322, 342-343, 348, 358, 426, 433, 435, 574, 577, 580, 584, 586, 589, 591, 625-626
 Regulations, 9, 12-13, 15, 26, 29, 37, 42, 46, 66-68, 72, 78-80, 82-83, 91, 108, 110, 123, 130, 134-135, 148, 151, 153, 160, 219, 221, 235, 237-240, 243, 245, 251, 269-270, 274, 277, 282, 294, 304, 313, 318, 328, 343-344, 348, 351, 354, 357, 359, 363, 369-370, 453, 497, 535, 555, 557, 559-560, 564, 567-568, 578-584, 586-589, 592, 598-599, 607, 618-619, 624-626, 647-648
 Tracking, 9, 17, 20, 45, 62, 107, 122, 124, 202, 221, 223, 327, 330, 363, 497, 505, 526, 552, 567, 572, 574, 577, 579, 584, 586, 589, 592, 625
 Medical equipment management, 19-20, 26, 34, 39, 59, 77, 82, 103, 107-110, 122-124, 130, 132, 159-160, 162, 171, 173, 175, 183, 205, 239, 243-245, 309, 315, 324, 555, 569, 572-573, 575, 625, 635, 637
 Medical Equipment Management Plan (JCAHO), 123, 239, 243-244, 315, 569, 572
 Medical equipment
 Accidents, 15, 19, 59, 73, 81, 107, 124, 132, 237, 251, 282, 315, 325, 341, 355, 414, 497, 542, 552, 581
 Acquisition, 1, 20, 27, 29, 34-36, 38-39, 60, 73-75, 77, 79, 81-82, 92-93, 103-104, 107-112, 122, 125, 127, 135, 148, 151-152, 155, 159-160, 164, 169-170, 172-173, 175, 189, 193, 207, 209, 221, 223, 237-238, 252, 298, 324, 329, 341, 366, 368, 471, 480, 497, 507, 527, 572, 581, 624-625, 633, 648
 Design, 1-4, 8, 15, 18, 20-21, 25, 35-36, 42, 61, 73, 82, 86-87, 97, 107, 123, 152, 188, 202, 205, 209, 237-240, 245, 249, 251, 300, 307, 318, 325, 329, 335, 347, 349, 354-355, 379, 383, 411-412, 527-528, 557, 569, 572-573, 575, 581, 612, 615, 617, 624-625, 648, 658
 Donations, 80, 82, 84, 93, 125, 155-160, 305, 308-309, 601
 Hazards, 1, 19, 21, 24, 26, 39, 104, 107, 125, 156, 202, 221, 237-239, 243-245, 251, 262, 282, 307, 325, 341, 343, 354-355, 379, 383, 414, 446, 528, 542, 552, 569, 572, 617, 625, 637
 Incidents, 1-2, 15, 20-21, 23, 25, 60, 104, 107, 122, 124-125, 154, 202, 209, 220, 237-240, 244, 249, 261-262, 267, 298, 307, 311, 315, 324-325, 347, 383, 436, 497, 572, 575, 617, 625, 648
 Inspection & PM, 125-126
 Inventory, 4, 8, 19, 29, 35-36, 59, 74, 79-81, 94-95, 103-104, 107-111, 113, 122-127, 133-135, 151, 154, 164, 172, 183, 188, 199, 207, 223, 239, 252, 282, 300, 307, 339, 347, 383, 497, 507, 552, 569, 572, 575, 625, 637
 Maintenance, 1-2, 4, 8, 10, 15, 18-21, 26-31, 34-36, 38-39, 41, 49, 59-61, 71, 73-77, 79-82, 84, 86-87, 89, 91-95, 97, 103-104, 107-113, 122-127, 130-135, 137, 148, 151-152, 154-160, 162, 165-166, 169-170, 172-173, 189, 199, 202, 205, 207-209, 220-221, 223, 237-240, 244-245, 249, 252, 267, 282, 297-300, 305, 307-309, 311-312, 315, 318, 339, 343, 347, 354, 368, 383, 412, 414, 436, 480, 497, 506, 528, 542, 567, 569, 572, 575, 581, 601, 608, 613, 625, 635, 637, 648, 658
 Manufacturers, 3, 8, 10, 15, 19-21, 23-25, 28, 31, 35, 38, 41-42, 59-60, 79, 84, 86, 91, 97, 107, 109, 111, 123-124, 126-127, 130, 132, 135, 137, 148, 151-152, 154, 156, 158, 171, 173, 188, 207, 221, 237-240, 251, 261, 267, 282, 308, 312-313, 315, 324-325, 347, 349, 354, 366, 368, 412, 414, 436, 480, 497, 507, 542, 552, 555, 557, 567, 573, 575, 581, 612, 615, 625, 648
 Manufacturing, 2, 10, 20, 77, 107-108, 148, 160, 199, 335, 349, 480, 506, 557, 567, 612, 633
 Operators, 15, 25, 80, 84, 109, 111, 124, 148, 155-156, 158, 249, 312, 315, 324, 355, 436, 446, 506, 567, 635, 646, 648
 Purchasing, 4, 10, 19-21, 23-24, 26-27, 29-30, 35-36, 38, 42, 59, 65, 71, 80-82, 91, 97, 103-104, 107, 109-112, 124-127, 135, 148, 151-152, 154-155, 158, 160, 164, 166, 171-173, 176, 189, 193, 221, 237-238, 261, 282, 300, 307-308, 347, 366, 368, 383, 414, 507, 552, 575, 624, 646

- Recalls, 19-21, 23-24, 79, 107, 124-126, 154-156, 220-221, 223, 237, 239, 307, 316, 343, 625
- Regulations, 15, 26-27, 29, 42, 79-80, 82, 84, 91, 93, 108, 110, 123, 125, 130, 134-135, 148, 151, 154, 159-160, 176, 219, 221, 237-240, 243, 245, 251, 282, 307, 313, 318, 343, 354, 480, 497, 528, 555, 557, 567, 581, 624-625, 648
- Repair, 1, 4, 8, 15, 19-21, 24-25, 27, 29, 34-36, 38-39, 41, 49, 59-60, 73-74, 79-80, 86-87, 89, 91, 93, 97, 103-104, 107, 109, 113, 124-127, 130-135, 137, 148, 151, 155-156, 158-159, 170, 173, 183, 189, 193, 199, 202, 205, 207-209, 220-221, 223, 237-239, 297, 299-300, 305, 309, 312, 324-325, 349, 368, 383, 414, 436, 446, 471, 480, 507, 552, 557, 575, 601, 608, 613, 617, 625, 635, 637, 646
- Testing, 4, 18-21, 23-26, 28-30, 34, 36, 38-39, 42, 49, 79, 104, 107, 109, 125-126, 130-132, 135, 148, 151, 158, 170, 175, 183, 189, 199, 202, 208-209, 221, 223, 237-240, 243, 245, 249, 261-262, 267, 282, 297-300, 316, 318, 324-325, 335, 347, 368, 412, 414, 436, 446, 497, 506, 552, 557, 569, 572-573, 575, 608, 617, 624-625, 635, 646, 658
- Tracking, 9, 19-20, 24, 39, 107, 122, 124, 202, 221, 223, 307, 497, 552, 567, 572, 625
- Users, 1, 3, 9, 15, 19-21, 24-27, 30, 38, 49, 60, 75, 80, 82, 86, 97, 103-104, 107-109, 111-112, 122-127, 131-132, 135, 137, 148, 151-152, 154-156, 158, 162, 164, 166, 170, 173, 183, 189, 202, 207, 220, 223, 238, 244, 249, 252, 261, 298, 307-308, 312-313, 315-316, 324-325, 343, 347, 349, 354-355, 366, 368, 383, 446, 471, 480, 497, 506, 552, 569, 572, 575, 581, 625, 633, 635, 637, 648, 658
- Medical errors, 2, 10, 14, 43, 51, 227, 235, 237, 240-241, 245-246, 269, 353-354, 566, 603, 608, 624
