Contents

Contributors xiii

Introduction xvii

Section I Clinical Engineering 1

Introduction Raymond P. Zambuto

1. **Clinical Engineering: Evolution of a Discipline 3**
Joseph D. Bronzino
2. **History of Engineering and Technology in Health Care 7**
Malcolm G. Ridgway, George I. Johnston, and Joseph P. McClain
3. **The Health Care Environment 11**
Lee O. Welter
4. **Enhancing Patient Safety: The Role of Clinical Engineering 14**
American College of Clinical Engineering
5. **A Model Clinical Engineering Department 16**
Caroline A. Campbell
6. **Clinical Engineering in an Academic Medical Center 18**
Ira Soller
7. **Regional Clinical Engineering Shared Services and Cooperatives 26**
J. Tobey Clark
8. **Nationwide Clinical Engineering System 28**
Diego Bravar and Teresa dell'Aquila
9. **Clinical Engineering and Biomedical Maintenance in the United States Military 34**
Joseph P. McClain
10. **Careers, Roles, and Responsibilities 36**
Nicholas Cram
11. **Clinical Engineering at the Bedside 39**
Saul Miodownik
12. **The Clinical Engineer as Consultant 41**
J. Sam Miller

13. **The Clinical Engineer as Investigator and Expert Witness 43**

Jerome T. Anderson

14. **Careers in Facilities 49**

Bruce Hyndman

Section II Worldwide Clinical Engineering Practice 51

Introduction Enrico Nunziata

15. **World Clinical Engineering Survey 53**
Mariana Glouhova and Nicolas Pallikarakis
16. **Clinical Engineering in the United Kingdom 58**
Stuart J. Meldrum
17. **Clinical Engineering in Canada 62**
William M. Gentles
18. **Clinical Engineering in Estonia 65**
Siim Aid and Ole Golubjatnikov
19. **Clinical Engineering in Germany 67**
Vera Dammann
20. **Clinical Engineering in Brazil 69**
Lúcio Flávio de Magalhães Brito
21. **Clinical Engineering in Colombia 72**
Jorge Enrique Villamil Gutiérrez
22. **Clinical Engineering in Ecuador 78**
Juan Gomez
23. **Clinical Engineering in Mexico 80**
Adriana Velásquez
24. **Clinical Engineering in Paraguay 84**
Pedro Galvan
25. **Clinical Engineering in Peru 87**
Luis Vilcahuaman and Javier Brandán
26. **Clinical Engineering in Venezuela 89**
Ricardo Silva and Luis Lara-Estrella
27. **Clinical Engineering in Japan 91**
Hiroshi Kanai

28. Clinical Engineering in Mozambique 93

Enrico Nunziata and Momade Sumalgy

29. Clinical Engineering in the Middle East 97

Hashem O. Al-Fadel

Section III Health Technology Management 99

Introduction Thomas M. Judd

30. Introduction to Medical Technology Management Practices 101

Yadin David, Thomas M. Judd, and Raymond P. Zambuto

31. Good Management Practice for Medical Equipment 108

Michael Cheng and Joseph F. Dyro

32. Health Care Strategic Planning Utilizing Technology Assessment 110

Nicholas Cram

33. Technology Evaluation 114

Gary H. Harding and Alice L. Epstein

34. Technology Procurement 118

Gary H. Harding and Alice L. Epstein

35. Equipment Control and Asset Management 122

Matthew F. Baretich

36. Computerized Maintenance Management Systems 124

Ted Cohen and Nicholas Cram

37. Maintenance and Repair of Medical Devices 130

James McCauley

38. A Strategy to Maintain Essential Medical Equipment in Developing Countries 133

Michael Cheng

39. Outsourcing Clinical Engineering Service 135

Peter Smithson and David Dickey

40. New Strategic Directions in Acquiring and Outsourcing High-Tech Services by Hospitals and Implications for Clinical Engineering Organizations and ISOs 137

Donald F. Blumberg

41. Vendor and Service Management 147

Joseph F. Dyro

42. Health Care Technology Replacement Planning 153

J. Tobey Clark

43. Donation of Medical Device Technologies 155

Joseph F. Dyro

44. National Health Technology Policy 159

Thomas M. Judd

45. The Essential Health Care Technology Package 163

Peter Heimann, Andrei Issakov, and S. Yunkap Kwankam

46. Impact Analysis 171

Thomas M. Judd

Section IV Management 179

Introduction Alfred M. Dolan

47. Industrial/Management Engineering in Healthcare 181

George Seaman

48. Financial Management of Clinical Engineering Services 188

Binseng Wang

49. Cost-Effectiveness and Productivity 199

Larry Fennigkoh

50. Clinical Engineering Program Indicators 202

Dennis Autio

51. Personnel Management 206

James O. Wear

52. Skills Identification 212

Nicholas Cram

53. Management Styles and Human Resource Development 213

Alice L. Epstein and Gary H. Harding

54. Quality 219

Thomas M. Judd

Section V Safety 225

Introduction Marvin Shepherd

55. Patient Safety and the Clinical Engineer 227

Bryanne Patail

56. Risk Management 235

Alice L. Epstein and Gary H. Harding

57. Patient Safety Best Practices Model 241

Paul Vegoda and Carl Abramson

58. Hospital Safety Programs 243

Matthew F. Baretich

59. Systems Approach to Medical Device Safety 246

Marvin Shepherd

60. Interactions Between Medical Devices 249

Saul Miodownik

61. Single Use Injection Devices 251

Michael Cheng

62. Electromagnetic Interference with Medical Devices: *In Vitro* Laboratory Studies and Electromagnetic Compatibility Standards 254

Kok-Swang Tan and Irwin Hinberg

63. Electromagnetic Interference in the Hospital 263

W. David Paperman, Yadin David, and James Hibbetts

64. Accident Investigation 269

Joseph F. Dyro

65. The Great Debate on Electrical Safety—In Retrospect 281

Malcolm G. Ridgway

Section VI Education and Training 285

Introduction James O. Wear

66. Academic Programs in North America 287

Tim Baker

67. Clinical Engineering Education in Germany 294

Vera Dammann

68. Clinical Engineering Internship 297

Izabella A. Gieras and Frank R. Painter

69. Biomedical Engineering Technology Program 299

Bruce J. Morgan

70. Advanced Clinical Engineering Workshops 301

Joseph F. Dyro, Thomas M. Judd, and James O. Wear

71. Advanced Health Technology Management Workshop 305

Thomas M. Judd, Joseph F. Dyro, and James O. Wear

72. Distance Education 309

James O. Wear and Alan Levenson

73. Emerging Technologies: Internet and Interactive Video conferencing 312

Albert Lozano-Nieto

74. In-Service Education 315

James O. Wear

75. Technical Service Schools 317

Manny Roman

76. Clinical Engineering and Nursing 321

Thomas J. Bauld III, Joseph F. Dyro, and Stephen L. Grimes

77. Retraining Programs 328

James Gilchrist

78. Techno-Bio-Psycho-Socio-Medical Approach to Health Care 332

T. G. Krishnamurthy

Section VII Medical Devices: Design, Manufacturing, Evaluation, and Control 337

Introduction Gary H. Harding and Alice L. Epstein

79. Evolution of Medical Device Technology 339

Nandor Richter

80. Technology in Health Care 342

Jonathan A. Gaev

81. Medical Device Design and Control in the Hospital 346

Joel R. Canlas, Jay W. Hall, and Pam Shuck-Holmes

82. Medical Device Research and Design 350

P. Åke Öberg

83. Human Factors: Environment 353

William A. Hyman and Valory Wangler

84. Medical Devices: Failure Modes, Accidents, and Liability 355

Leslie A. Geddes

85. Medical Device Software Development 359

Richard C. Fries and Andre E. Bloesch

86. Comparative Evaluations of Medical Devices 366

James P. Keller

87. Evaluating Investigational Devices for Institutional Review Boards 369

Salil D. Balar

Section VIII Medical Devices: Utilization and Service 371

Introduction Joseph F. Dyro

88. Intensive Care 373

Saul Miodownik

89. Operating Room 376

Chad J. Smith, Raj Rane, and Luis Melendez

Introduction

Joseph F. Dyro

Editor-in-Chief
Setauket, NY

Clinical Engineering: A Definition

The American College of Clinical Engineering defines a clinical engineer (CE) as: “a professional who supports and advances patient care by applying engineering and managerial skills to health care technology.” Clinical engineering is a subset of biomedical engineering. Whereas biomedical engineering is practiced primarily in academic institutions, the research laboratory, and manufacturing, clinical engineering is practiced in hospitals and other environments where medical device technologies are utilized. The purpose of the *Clinical Engineering Handbook* is to provide a central core of knowledge and essential information the clinical engineer needs to practice the profession.

Health Care and Clinical Engineering

Clinical engineering emerged as a discipline in the latter half of the twentieth century as increasing numbers of complex electronic and mechanical medical devices entered the health care environment for preventive, therapeutic, diagnostic and restorative applications. Within the complex environment of the modern hospital, clinical engineering is concerned primarily with devices but recognizes that interactions between drugs, procedures, and devices commonly occur and must be understood and managed to ensure safe and effective patient care. Clinical engineering, first practiced in the hospital, has extended its sphere of influence as medical devices are utilized increasingly in extended care facilities and in the home. Career mobility and diversity has increased as manufacturers and regulatory agencies have recognized the important role clinical engineers play in the research, development, manufacturing and regulation of medical devices. Clinical engineers apply their talents in all areas of health care including the following:

- Medical device industry
- Government regulatory agencies
- Standards organizations
- Hospitals, clinics, extended care and long-term care facilities
- Regional and national service organizations
- Consultancies for litigation support, regulatory compliance, program evaluation, and research
- Academic institutions
- Technical training schools

Engineers who are active in the health care sector have great opportunities to contribute to long-term quality enhancement by developing new techniques or improving existing ones. By working daily with commercially available medical devices and observing how products are used in practice, the CE gains valuable knowledge that, when coupled with keen insight and creativity, can lead to ways to improve existing techniques or to solve long-standing problems. The CE has a perspective on developmental requirements, an extremely valuable attribute in order to function as an innovator. Furthermore, the CE's proximity to the point of health care delivery provides ample opportunities for the testing and trial of new products in the end-user environment. In the pursuit of improvements in health care, many with expertise in the medical sciences, doctors, nurses, therapists, collaborate well with engineers; for they understand the engineer's gifted ability to analyze problems and synthesize solutions. The beneficial result of such analysis and synthesis, the warp and weft of the engineer's mantle, is invention, the creation of something useful, an object, a machine, or a technique, that did not exist before.

Clinical engineering was born from the concept elaborated by Cesar Caceres over two decades ago, that engineering attributes, i.e., analysis and synthesis, are relevant and necessary to improve health care. Over the last two decades, however, the engineering aspects of the profession were eroded as hospital administrators and engineers themselves viewed the primary clinical engineering activity as medical device inspection, maintenance and repair. Today, the original concept of clinical engineering has reemerged, largely in response to the driving forces of cost-control, utilization optimization, regulatory require-

ments, patient safety and human error awareness, and increasing complexity of the technological environment. For example, among the forces of change were the revelations of inadequacies in the so-called *health care delivery system* contained in the Institute of Medicine's year 2000 report entitled *To Err is Human*. Systemic ailments in this *system* cry out for reengineering. No longer can clinical engineering be content with following routine maintenance and repair procedures when the need is so great for making engineering changes in the healthcare arena that will support and advance patient care. The Handbook contains many illustrations of the benefits of practicing the engineering aspects of the profession.

The enormous potential of highly competent, well-educated, talented, and skilled clinical engineers is now tapped for inventions, technical development, and systems analysis. Through the advocacy and public policy efforts of the American College of Clinical Engineering (ACCE) and the ACCE Healthcare Technology Foundation, the value of clinical engineering to the health care community is clearly recognized and enthusiastically embraced. Clinical support, engineering at the bedside, health care delivery process improvement, enhanced technology utilization and patient care, and device design are at the core of the clinical engineering discipline. The listing of the many facets of the discipline of clinical engineering is shown in the accompanying figure. Clinical engineering will continue to adapt as technology advances. Engineering in primary health care is but one example of how clinical engineering can proactively influence the quality of life by disease prevention and health improvement at a reasonable cost.

This Handbook will serve as an instructional tool in clinical engineering academic programs and a desk reference for all clinical engineers and others involved with health care technologies. The author, with experience as a faculty member of many ACCE Advanced Clinical Engineering Workshops, a practicing clinical engineer, and a university educator, is keenly aware of the educational requirements of the clinical engineer. This Handbook incorporates all the essential elements of clinical engineering and will serve as a solid platform upon which to build the management and technical skills of the profession. It includes all the subjects that are necessary for a comprehensive educational curriculum for clinical engineers and others who manage medical device technologies

Within each Handbook section can be found an elaboration upon each of the facets of the discipline of clinical engineering, which are summarized in the accompanying figure.

Safety and Efficacy of Medical Device Technology

The methodology for making the patient environment safer is described in the section on Safety. Clinical engineering response to the patient safety movement involves active participation in risk management, hospital safety programs, and accident investigation. The complex interactions involving patient, devices, users, facilities, and the environment require a systems approach to medical device safety. For example, the emergence of a wide variety of wireless technologies and the proliferation of devices that produce and are receptive to electromagnetic energy has drawn attention to deleterious effects of interference caused by this energy. Means for assessing and managing the risks posed by EMI are presented. A historical account of the emergence of, reaction to, and effect of the electrical safety scare of the 1970s puts electrical safety in clear perspective *vis-à-vis* other more significant safety issues and demonstrates the folly of unreasonable assumptions and wild extrapolations that are not well-grounded in scientific fact.

Medical Devices

The different phases in the medical device technology life cycle, such as research, design, manufacture, evaluation, control, utilization, service, standards, regulations, and law are addressed in several sections: Medical Devices: Design, Manufacture, Evaluation and Control; Medical Devices: Utilization and Service; and Standards, Regulations, and the Law. The evolution of medical technology from the earliest recorded history to the present day clearly demonstrates the contributions of engineering to the advancement of health care. Development of medical devices must involve research, design, clinical test-

ing, and good manufacturing practices. Human factors, failure mode analysis, and software development are discussed as they affect device performance and safety. Medical device utilization is described in the hospital. In addition to general hospital devices, specialty devices are described that are utilized in the following selected areas and services of the hospital: intensive care, operating room, anesthesiology, imaging, perinatology, and cardiovascular services. Standards and regulations applicable to medical devices and clinical engineering are presented. International and national perspectives on standards are addressed including those promulgated by the Joint Commission on Accreditation of Healthcare Organizations, United States Food and Drug Administration, International Standards Organization, the American National Standards Institute, and the Association for the Advancement of Medical Instrumentation.

Health Care Technology Management

Health care technology management is a core clinical engineering discipline entailing assessment, strategic planning, evaluation, acquisition, utilization, maintenance, asset control, replacement planning, and quality assurance. The first chapter, Introduction to Medical Technology Management Practices, is followed by chapters on strategic planning, evaluation, procurement, asset management, management systems, maintenance, sources of service and service management, and replacement planning. The chapters on national health technology policy, impact analysis, donations, good management practice for medical equipment, strategies to maintain essential medical equipment and essential healthcare technology package are of particular significance to countries with developing and emerging economies.

Management

Several chapters describe the management skills required for effective clinical engineering practice including utilization analysis, financial management, cost-effectiveness and productivity measurement, personnel management, and quality assessment and improvement.

Professionalism and Ethics

Advocacy efforts, certification programs, and active participation in professional societies are discussed in the section on Professionalism and Ethics. The American College of Clinical Engineering, the first organization in the world founded to represent solely the interest of clinical engineers, is described in detail. In addition, examples of local and regional clinical engineering organizations are presented in order that they may serve as models of organizations for countries and regions where clinical engineering is developing.

Information

The section on Information reveals the effect that the explosion of information technology (i.e., computers and methods for utilizing information to advance patient care) has had upon clinical engineering. Following the chapter on Information Systems Management, chapters address Physiological Monitoring and Clinical Information Systems, Advanced Diagnostics and Artificial Intelligence, Real-Time Executive Dashboards and Virtual Instrumentation, Telemedicine, Picture Archiving and Communication Systems, Wireless Medical Telemetry, Health Insurance Portability and Accountability Act, Y2K and Clinical Engineering, and The Integration and Convergence of Medical and Information Technologies.

Facilities and the Clinical Environment

The safe and effective operation of medical devices and systems depends to a great extent on the physical plant and its utilities and support systems such as heating, venti-

lation, and air conditioning, electrical distribution systems, medical gas systems, sanitation systems, and water supply. Radiation safety, facilities design and construction, and disaster preparedness are all issues with which the clinical engineer must knowledgeable as they directly relate to the medical devices utilized within a health care institution.

Education

Many journal articles and several textbooks have been written over the years on the subject of clinical engineering. These have served well to educate generations of clinical engineers. The author owes a debt of gratitude to those who have contributed to the literature with books on clinical engineering including Barry Feinberg, Cesar Caceres, Joseph Bronzino, John Webster, and Albert Cook. In the course of discussions with colleagues at national and international clinical engineering conferences, colleagues recognized the need for a comprehensive text that encompasses all aspects of clinical engineering. This Handbook is built on the solid foundation of information presented over the years by experts in the field. The section on Education includes chapters on Academic Programs in North America, Advanced Clinical Engineering Workshops, Distance Learning, In-Service Education, Technical Training Schools, Retraining Programs, and Clinical Engineering Internship. Educational programs in Germany and India are described.

Worldwide Clinical Engineering Practice

Clinical engineering is practiced around the globe in countries at all stages of economic development. The lead chapter of the section on Worldwide Clinical Engineering Practice is World Clinical Engineering Survey. This is followed by descriptions of the practice of clinical engineering in fifteen countries throughout different regions of the world. Developing countries and emerging economies, whose resources tend to be scarce and where lack of effective technology management is keenly felt, have relatively more to gain from the implementation of clinical engineering than economically advanced nations.

The Future

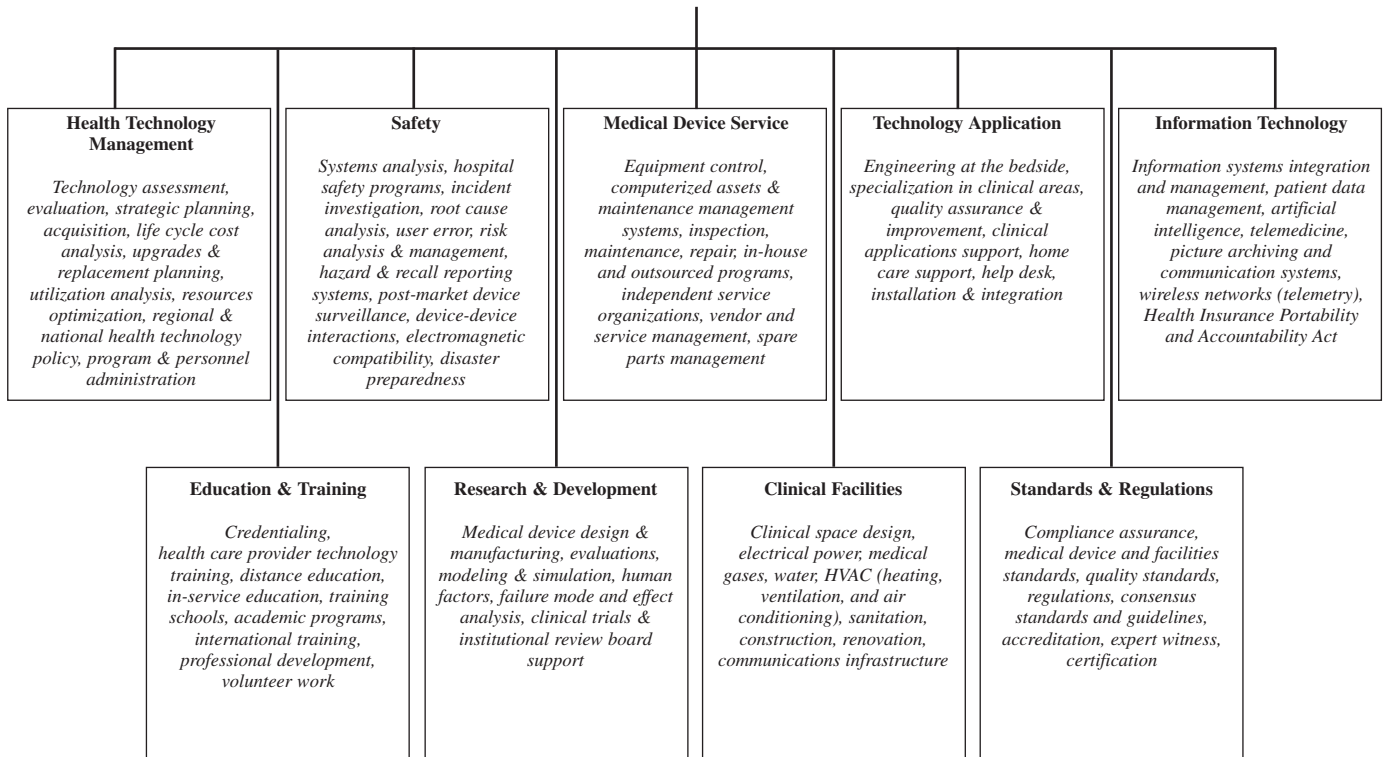

As systems and methods of addressing the well-being of the inhabitants of this planet change, so too will the discipline of clinical engineering. The section on The Future leads the reader one step in that direction by suggesting ways by which clinical engineering can contribute to improvement in health care. It is this editor's hope that those entering the field of clinical engineering today will one day be among those that write the next edition of this Handbook.

Acknowledgments

I thank my friend and colleague, Joseph D. Bronzino, for recommending to the publisher that I undertake the task of editing the *Clinical Engineering Handbook*. He told me at a meeting several years ago that when we leave this earth the knowledge in our brain is lost forever. So, write! I heeded that advice and urge all others to do likewise. I thank all authors from across the globe who contributed their time and energy to write section introductions and chapters. I thank the following members of the Handbook Advisory Board for their review of and comment on the initial table of contents: Matthew Baretich, Joseph D. Bronzino, Andrei Issakov, Bruce J. Morgan, Robert Morris, Åke Öberg, Jennifer C. Ott, Frank R. Painter, Nicolas Pallikarakis, Nandor Richter, Malcolm G. Ridgway, Binseng Wang, and Raymond P. Zambuto. Their comments and suggestions helped refine the Handbook's scope and content.

I give special thanks to my kind and understanding wife, Betsy, for her patience, forbearance, encouragement, and support throughout my long hours at the keyboard.

The Discipline of Clinical Engineering

Section I

Clinical Engineering

Raymond P. Zambuto

CEO, Technology in Medicine, Inc.
Holliston, MA

The place is Olduvai Gorge. The time is 2 million BC. Homo habilis, “handy man,” uses a sharpened stone to remove a splinter. Fast forward to the twenty-first century. The place is Boston, Massachusetts. A cardiologist evaluates a child in distress in São Paulo, Brazil using real-time video teleconferencing with the child’s physician.

Human beings have used tools in their medical care from the beginning. Like people, those tools have evolved over the ages. The sharpened stones have become complex instrumentation- and technology-based clinical systems of care. As medical “tools” became more sophisticated, the technologies that they employed grew apart from the core competencies of the users. Today, medical technology is rooted in science, designed using engineering, and applied interactively in a demanding environment. Furthermore, clinical systems go beyond the technology to include policies, procedures, and protocol that ensure safety, security, and privacy as well as efficacy. This is the realm of clinical engineering.

Clinical engineering began with the application of engineering principles to the economic solution of clinical problems. It relied heavily on a body of knowledge that drew on electrical and mechanical engineering, physiology, human factors, and chemistry.

The clinical engineer was envisioned to be the professional who would bridge the communications gaps among medical, administrative, and engineering personnel in hospitals, thus playing a direct role in the improvement of care by leveraging technological solutions to patient diagnosis and therapy. Employment opportunities were seen in research and design as well as in the clinical environment. As such, the clinical engineer was required to possess specialized knowledge, such as medical terminology and sterile technique, that was not provided in the traditional engineering curriculum.

Today, as in the past, in typical practice the engineering foundation gives the clinical engineer analytical tools to solve problems from the perspective of an “outsider,” while the specialized knowledge makes the clinical engineer a member of the health care team. For example, the engineering education tells the clinical engineer that an intensive care room is properly sized to hold the patient, equipment, and personnel. Human factors training might reveal that the room does not give adequate space for the staff to work in an emergency.

As an interdisciplinary practitioner, the clinical engineer is something of a chameleon. To one person, the clinical engineer is an advisor on technology selection; to another, an incident investigator or patient-safety expert; to a third person, a partner in clinical studies. Clinical engineers are everywhere on the health scene, often in jobs that parallel the work of other professionals, including medical physicists, biomedical equipment managers, and information-technology specialists.

This combination of diverse training with varied job experiences can confuse the casual observer who wishes to “define” a clinical engineer in the same way that one would identify a doctor, nurse, or accountant. As clinical engineering has evolved and matured as a unique field, its members have applied their professional skills to an ever-changing panorama of applications, driven by the changing landscape of the health care industry.

When the first formally trained clinical engineers came into the work force, the industrialized world was in the midst of a post-war health care boom. That boom eventually ended as the cost of health care reached the point where businesses and governments sought to control it. The result has been a plethora of systems including state-sponsored health care, single-payer systems, Health Maintenance Organization (HMO)-based care, capitated payment schemes, systems of hospitals, both for- and nonprofit, and in some cases, rationed care.

While all of these changes were occurring, the developing world was struggling against poverty, basic diseases, and AIDS, all the while hindered by insufficient resources for care. While one part of the world began to shut down excess capacity by closing and merging hospitals, another part was still building its health care infrastructure. Clinical engineers have been called upon to apply their skills in each of these situations, always looking for economic solutions to technology-based problems. The technology may be high or low, but the quality-of-care-vs.-cost tightrope is always being walked.

While economic forces continue to shape health care, another external factor that is rising in influence is the growth of electronic data processing and communications. Health care systems are establishing enterprise-wide data processing, storage, and transfer, and are bringing complex clinical systems on line. In tomorrow’s environment, information management will continue to play a wider role in the management of health care and its cost and therefore will shape many aspects of equipment design and technology manage-

ment. The implementation of smarter technology in clinical equipment, as well as distributed technologies such as telemedicine and remote diagnosis, will create new applications for clinical engineers in terms of deployment, economics, efficacy, and security.

This wide range and rapid change in clinical engineering practice is atypical for a relatively young profession. While the more mature engineering disciplines saw major changes in their practice as their “body of knowledge” expanded, those changes occurred over many decades or even centuries. Clinical engineering, however, being born in the second half of the twentieth century, has been impacted from the start by the most prolific growth in medical discovery and technology advance in history. And yet, the basic elements of the profession have remained the same through all of the diverse ways that those elements are applied.

Clinical engineers are, particularly in the industrialized nations, commonly perceived primarily as managers of the biomedical equipment maintenance function. While this job is often filled by a clinical engineer, the stereotype does a disservice to both the clinical engineering and the biomedical equipment technician fields. Management of the maintenance shop can be a career path for the management-oriented technician as well as for the engineer.

While these perceptions reflect the most visible application of clinical engineering’s skill set, they exclude much of what a clinical engineer brings to the workplace. For example, in the mid-1970s, clinical engineers were intimately involved in health care industry issues unrelated to biomedical department management, including: electrical safety of invasive medical equipment, incident investigations, design of medical equipment, isolated power in the operating room, fire hazards in oxygen-rich atmospheres, patient-connection standards and interlocks, infection control, in-service education, electromagnetic interference with instrumentation, codes and standards writing-and-interpretation, and assessment of new technologies. At the same time, clinical engineers also participated in the development of equipment-related systems for assuring the safety and efficacy through planned maintenance.

More recently, these same clinical engineers are confronting issues that range from acquisition and installation of Picture Archiving and Communications Systems (PACS) to standards for the refurbishing of medical equipment. Taken in the aggregate, these applications cover a broad, ever-changing body of knowledge.

Every profession possesses a unique body of knowledge consisting of a basic skill set plus derivative knowledge based on current practices and applications. The derivative knowledge is often the more visible trait, but it is also the more volatile. The underpinnings of the profession are the basic skills, and they remain constant.

For clinical engineering, the basic skill set is the combination of classical engineering education supplemented with life-science and management course work such as physiology, human factors, psychology, and economics. With those basic tools, the clinical engineer is prepared to address a variety of issues.

Despite this broad education, in the real world clinical engineering work often entails decisions that must be made without knowing all of the facts, and with no crystal ball regarding the outcome or consequences. In some situations, such as the investigation of an incident, the need to use one’s judgment is apparent. In other situations, such as the balancing of equipment maintenance schedules, the clinical engineer must consider a variety of sometimes conflicting factors such as accreditation requirements, real need, budget, and potential harm to the patient. The use of professional judgment is more transparent in this type of situation. Similarly, the “repair or replace” decision can be complicated by staff capability, the hospital’s census, and the strategic medical plan of the institution, not just factors of cost and budget.

The common denominator for clinical engineers is the patient, regardless of job description or employer. The fundamental drive to put their talents to a better purpose is what usually drives engineers to choose health care over a more lucrative career in the defense or computer industries. That fundamental drive to improve patient care through the use of engineering can be exercised in many venues. It might be by finding economic solutions to problems, managing medical equipment to ensure its safe operation and continuous availability, or designing the next generation of technology into that equipment. In every situation, however, the patient is always seen as the ultimate customer.

This focus on the patient is the centerpiece of the clinical engineer’s professional ethics. In addition to ensuring the individual patient’s right to safe and efficacious equipment, clinical engineers also function in applications that more broadly impact patient

welfare and the public good. These applications include: incident investigations, design of medical equipment, infection control, in-service education, electromagnetic interference with equipment function, codes and standards interpretation, and assessment of new technologies. In each of these areas, clinical engineers are working to improve safety, to reduce costs, and to continuously improve the health care system.

Additionally, non-hospital-based clinical engineers, such as those in clinical research, education, forensics, consulting, and manufacturing, often play a direct role in situations that directly impact the public good. These clinical engineers work different applications, but their expertise is brought to bear directly on patient outcomes, clinician performance, and hospital management.

The result of this ethical commitment by clinical engineers is the engendering of a public trust. That public trust in turn imputes a degree of personal responsibility for the actions or omissions of the clinical engineer, thus completing the picture of the professional. This mindset, shaped in the educational process and reinforced by professional groups such as the American College of Clinical Engineering, gives the clinical engineer a special identification with the good of the patient. As a result, clinical engineers, while generally protected by the corporate shield of the hospital or another employer, will make every effort to ensure that the decisions they make, and the actions they take, are thoroughly investigated and based on firm foundations.

Today, clinical engineering continues to mature as a profession. Its earlier over-identification with equipment maintenance is gradually giving way to an understanding of the broader tools that the clinical engineer brings to the table. One of the primary drivers behind this effect is the financial pressure on hospitals and the need to improve utilization. As a result, equipment and system design is being driven to more complexity and automation. This increased complexity ties the technology to the financial performance of the institution, as well as to patient diagnosis and treatment. The management of health

care continues to become intertwined with higher levels of technology and more complex systems, placing increased demands for the skills of the clinical engineer, while the recognition that properly engineered technology solutions are more cost-effective has improved the visibility of clinical engineering to the management structure.

As technology continues to assume a greater role in care, its management will continue to be elevated in stature. The cross-linking of medical technology with communications and data processing technologies, will foster the development of a central management function to span the "technology bundle" as the medical equipment of today becomes the "front end" of tomorrow's clinical information system. This "chief technology officer" will need to interface with the medical, administrative, and engineering disciplines of the future. Eventually, another final shift will occur from a focus on the technology to a focus on the information itself. This will create a new set of challenges and opportunities for clinical engineering.

In the nine chapters that comprise this first section of the *Handbook of Clinical Engineering*, a team of authors unparalleled in the industry critically and expertly defines the profession. Covering a range of topics, they examine the origins of the profession, career paths, work environments, and topics concerning clinical engineers' relation to health care and to technology in health care.

The section also includes practical accounts of the daily activities of clinical engineers and a detailed exploration of the expanding role of the clinical engineer in an important activity that benefits the public good, that of process improvement for the reduction of medical errors.

Information on the need for and practice of clinical engineering around the world will be emphasized here, including a chapter that exclusively concerns World Health Organization (WHO) technology guidelines. These chapters demonstrate the differences and the wide range of opportunities that exist for the future of a profession that looks very bright, indeed.

1

Clinical Engineering: Evolution of a Discipline

Joseph D. Bronzino

Vernon Roosa Professor of Applied Science,
Department of Engineering
Trinity College
Hartford, CT

Technological innovation has continually reshaped the field of medicine and the delivery of health care services. Throughout history, advances in medical technology have provided a wide range of positive diagnostic, therapeutic, and rehabilitative tools. With the dramatic role that technology has played in shaping medical care during the latter part of the 20th century, engineering professionals have become intimately involved in many medical ventures. As a result, the discipline of biomedical engineering has emerged as an integrating medium for two dynamic professions: medicine and engineering. Today, biomedical engineers assist in the struggle against illness and disease by providing materials, tools, and techniques (such as medical imaging and artificial intelligence) that can be utilized for research, diagnosis, and treatment by health care professionals. In addition, one subset of the biomedical engineering community, namely clinical engineers, has become an integral part of the health care delivery team by managing the use of medical equipment within the hospital environment. The purpose of this chapter is to discuss the evolution of clinical engineering, to define the role played by clinical engineers, and to present the status of the professionalization of the discipline and to reflect upon its future.

What Is Clinical Engineering?

Many of the problems confronting health care professionals today are of extreme interest to engineers because they involve the design and practical application of medical devices and systems—processes that are fundamental to engineering practice. These medically related problems can range from very complex, large-scale constructs, such as the design and implementation of automated clinical laboratories, multiphasic screening facilities, and hospital information systems, to the creation of relatively small and “simple” devices, such as recording electrodes and biosensors that are used to monitor the activity of specific physiological processes in a clinical setting. Furthermore, these problems often involve addressing the many complexities found in specific clinical areas, such as emergency vehicles, operating rooms, and intensive care units.

The field of biomedical engineering, as it has evolved, now involves applying the concepts, knowledge, and approaches of virtually all engineering disciplines (e.g., electrical, mechanical, and chemical engineering) to solve specific health care-related problems (Bronzino, 1995, 2000). When biomedical engineers work within a hospital or clinical environment, they are more properly called clinical engineers.

But what exactly is the definition of a “clinical engineer”? Over the years, a number of organizations have attempted to provide an appropriate definition (Schaffer and Schaffer, 1992). For example, the AHA defines a clinical engineer as:

- “a person who adapts, maintains, and improves the safe use of equipment and instruments in the hospital,” (AHA, 1986).

The American College of Clinical Engineering defines a clinical engineer as:

- “a professional who supports and advances patient care by applying engineering and managerial skills to health care technology,” (Bauld, 1991).

The definition that the AAMI originally applied to board certified practitioners describes a clinical engineer as:

- “a professional who brings to health care facilities a level of education, experience, and accomplishment which will enable him to responsibly, effectively, and safely manage and interface with medical devices, instruments, and systems and the user thereof during patient care...” (Goodman, 1989).

For the purpose of certification, the Board of Examiners for Clinical Engineering Certification considers a clinical engineer to be:

- “an engineer whose professional focus is on patient-device interfacing; one who applies engineering principles in managing medical systems and devices in the patient setting. (ICC, 1991).

The *Journal of Clinical Engineering* has defined the distinction between a biomedical engineer and a clinical engineer by suggesting that the biomedical engineer:

- “applies a wide spectrum of engineering level knowledge and principles to the understanding, modification or control of human or animal biological systems (Pacela, 1991).

Finally, in the book “Management of Medical Technology,” a clinical engineer was defined as:

- “an engineer who has graduated from an accredited academic program in engineering or who is licensed as a professional engineer or engineer-in-training and is engaged in the application of scientific and technological knowledge developed through engineering education and subsequent professional experience within the health care environment in support of clinical activities (Bronzino, 1992).

It is important to emphasize that one of the major features of these definitions is the clinical environment (i.e., that portion of the health care system in which patient care is delivered). Clinical activities include direct patient care, research, teaching, and management activities that are intended to enhance patient care.

Engineers were first encouraged to enter the clinical scene during the late 1960s in response to concerns about patient safety as well as the rapid proliferation of clinical equipment, especially in academic medical centers. In the process, a new engineering discipline—clinical engineering—evolved to provide the technological support that was necessary to meet these new needs. During the 1970s, a major expansion of clinical engineering occurred, primarily due to the following events (Bronzino and Hayes, 1988; Bronzino, 1992):

- The Veterans’ Administration (VA), convinced that clinical engineers were vital to the overall operation of the VA hospital system, divided the country into biomedical engineering districts, with a chief biomedical engineer overseeing all engineering activities in the hospitals in a district.
- Throughout the United States, clinical engineering departments were established in most large medical centers and hospitals and in some smaller clinical facilities with at least 300 beds.
- Clinical engineers were hired in increasing numbers to help these facilities to use existing technology and to incorporate new technology.

Having entered the hospital environment, routine electrical safety inspections exposed the clinical engineer to all types of patient equipment that were not being properly maintained. It soon became obvious that electrical safety failures represented only a small part of the overall problem posed by the presence of medical equipment in the clinical environment. This equipment was neither totally understood nor properly maintained. Simple visual inspections often revealed broken knobs, frayed wires, and even evidence of liquid spills. Investigating further, it was found that many devices did not perform in accordance with manufacturers’ specifications and were not maintained in accordance with manufacturers’ recommendations. In short, electrical safety problems were only the tip of the iceberg. By the mid-1970s, complete performance inspections before and after use became the norm, and sensible inspection procedures were developed (Newhouse et al., 1989). Clinical engineering departments became the logical support center for all medical technologies. As a result, clinical engineers assumed additional responsibilities, including the management of high-technology instruments and systems used in hospitals, the training of medical personnel in equipment use and safety, and the design, selection, and use of technology to deliver safe and effective health care.

In the process, hospitals and major medical centers formally established clinical engineering departments to address these new technical responsibilities and to train and supervise biomedical engineering technicians to carry out these tasks. Hospitals that established centralized clinical engineering departments to meet these responsibilities used clinical engineers to provide the hospital administration with an objective opinion of equipment function, purchase, application, overall system analysis, and preventive maintenance policies. With the in-house availability of such talent and expertise, the hospital was in a far better position to make more effective use of its technological resources (Jacobs, 1975; Bronzino, 1977; 1986; 1992). It is also important to note that competent clinical engineers, as part of the health care system, also created a more unified and predictable market for biomedical equipment. By providing health care professionals with needed assurance of safety, reliability, and efficiency in using new and innovative equipment, clinical engineers identified poor quality and ineffective equipment much more readily. These activities, in turn, led to a faster, more appropriate utilization of new medical equipment and provided a natural incentive for greater industrial involvement—a step that is an essential prerequisite to widespread use of any technology (Newhouse et al., 1989, Bronzino, 1992). Thus, the presence of clinical engineers not only ensured the establishment of a safer environment, but also facilitated the use of modern medical technology to make patient care more efficient and effective.

Today, clinical engineers are an integral part of the health care delivery team. In fact, their role is multifaceted. Figure 1-1 illustrates the multifaceted role played by clinical engineers. They must successfully interface with clinical staff, hospital administrators and regulatory agencies to ensure that the medical equipment within the hospital is safely and effectively used.

To further illustrate the diversity of their tasks, some typical pursuits of clinical engineers are provided below:

- Supervision of a hospital clinical engineering department that includes clinical engineers and biomedical equipment technicians (BMETs)
- Pre-purchase evaluation and planning for new medical technology
- Design, modification, or repair of sophisticated medical instruments or systems
- Cost-effective management of a medical equipment calibration and repair service
- Safety and performance testing of medical equipment by BMETs
- Inspection of all incoming equipment (new and returning repairs)
- Establishment of performance benchmarks for all equipment
- Medical equipment inventory control
- Coordination of outside services and vendors
- Training of medical personnel in the safe and effective use of medical devices and systems
- Clinical applications engineering, such as custom modification of medical devices for clinical research or evaluation of new noninvasive monitoring systems
- Biomedical computer support
- Input to the design of clinical facilities where medical technology is used (e.g., operating rooms (ORs) or intensive-care units).
- Development and implementation of documentation protocols required by external accreditation and licensing agencies

Clinical engineers thereby provide extensive engineering services for the clinical staff and, in recent years, physicians, nurses, and other clinical professionals have increasingly accepted them as valuable team members. The acceptance of clinical engineers in the hospital setting has led to different types of engineering-medicine interactions, which in turn have improved health care delivery. Furthermore, clinical engineers serve as a significant resource for the entire hospital. Since they possess in-depth knowledge regarding available in-house technological capabilities and the technical resources available from outside firms, the hospital is able to make more effective and efficient use of all of its technological resources.

The Role of Clinical Engineering Within the Hospital Organization

Over the years, management organization within hospitals has evolved into a diffuse authority structure that is commonly referred to as the “triad model.” The three primary components are the governing board (trustees), hospital administration (CEO and administrative staff), and the medical staff organization.

Clinical Engineering Program

In many hospitals, administrators have established clinical engineering departments to manage effectively all the technological resources, especially those relating to medical equipment, that are necessary for providing patient care. The primary objective of these departments is to provide a broad-based engineering program that addresses all aspects of medical instrumentation and systems support.

Figure 1-2 illustrates the organizational chart of the medical support services division of a typical major medical facility. Note that within this organizational structure, the director of clinical engineering reports directly to the vice president of medical support services. This administrative relationship is extremely important because it recognizes the important role that clinical engineering departments play in delivering quality care. It should be noted, however, that in other organizational structures, clinical engineering services fall under the category of “facilities,” “materials management,” or even simply “support services.”

In practice, there is an alternative capacity in which clinical engineers can function. They can work directly with clinical departments, thereby bypassing much of the hospital hierarchy. In this situation, clinical departments can offer the clinical engineer both the chance for intense specialization and, at the same time, the opportunity to develop a personal relationship with specific clinicians based on mutual concerns and interests (Wald, 1989). What is important today is the presence of clinical engineering at the appropriate point in the organizational structure for it to have a maximum impact on the proper use and management of modern medical technology (Bronzino, 1992; 1995; 2000).

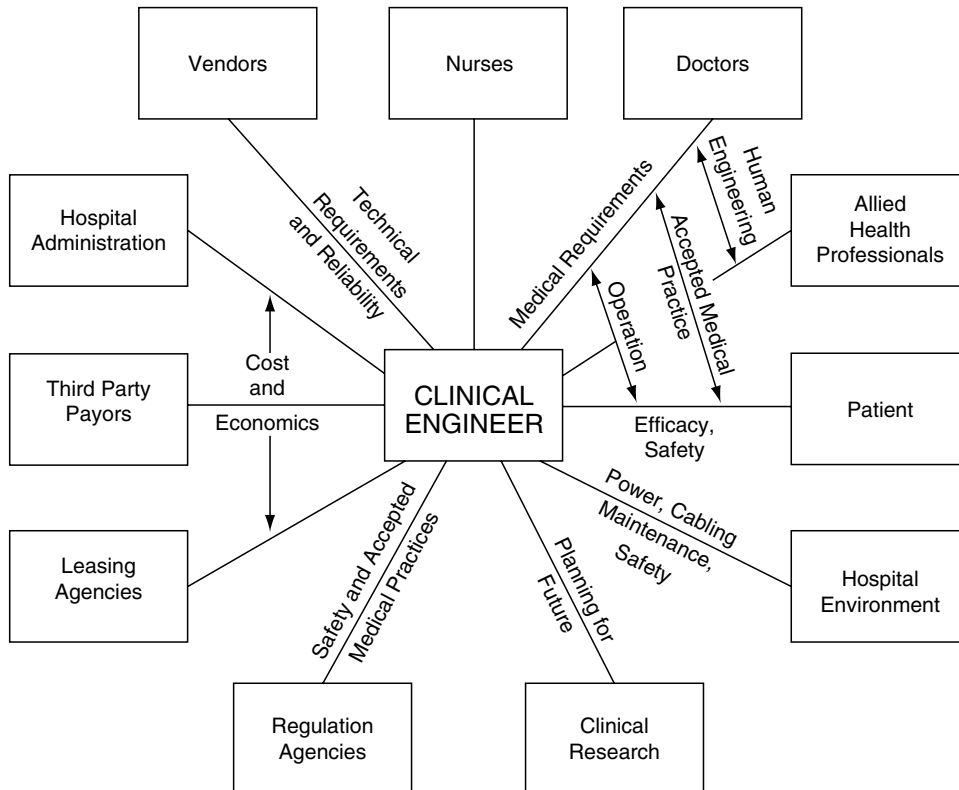

Figure 1-1 Diagram illustrating the range of interactions in which a clinical engineer might be required to engage in a hospital setting.

MEDICAL SUPPORT SERVICES DIVISION

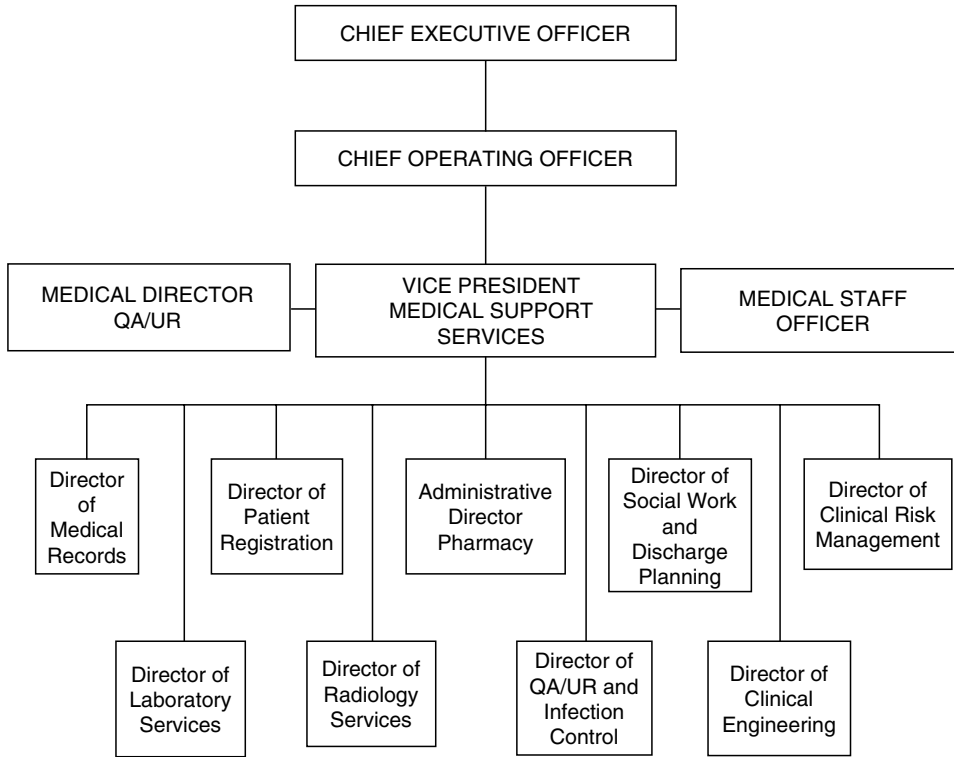

Figure 1-2 Organizational chart of medical support services division for a typical, major medical facility. This organizational structure points out the critical interrelationship between the clinical engineering department and the other primary services provided by the medical facility.

Major Functions of a Clinical Engineering Department

The role of the clinical engineer in today's hospital can be both challenging and gratifying because the care of patients requires a greater partnership between medical staff and modern technology. As previously discussed, this interchange has led to a close working relationship between the clinical engineer and many members of the medical and hospital staff. The team approach is key to the successful operation of any clinical engineering program. Figure 1-3 illustrates the degree of teamwork and interdependence that is required in order to maintain constructive interrelationships. In this matrix presentation, it is important to note that the health care team approach to the delivery of patient care creates both vertical and lateral reporting relationships. Although clinical engineers report hierarchically to their hospital administrator, they also interact with hospital staff to meet patients' requirements.

As a result of the wide-ranging scope of interrelationships within the medical setting, the duties and responsibilities of clinical engineering directors continue to be extremely diversified. Yet, a common thread is provided by the very nature of the technology that they manage. Directors of clinical engineering departments are usually involved in the following areas:

- Developing, implementing, and directing equipment management programs. Specific tasks include evaluating and selecting new technology, accepting and installing new equipment, and managing the inventory of medical instrumentation, all in keeping with the responsibilities and duties defined by the hospital administration. The clinical engineering director advises the administrator of the budgetary, personnel, space, and test equipment requirements that are necessary to support this equipment management program.
- Advising administration and medical and nursing staffs in areas such as safety, the purchase of new medical instrumentation and equipment, and the design of new clinical facilities
- Evaluating and taking appropriate action on incidents attributed to equipment malfunction or misuse. The clinical engineering director summarizes the technological significance of each incident and documents the findings of the investigation, subsequently submitting a report to the appropriate hospital authority and, according to the Safe Medical Devices Act of 1990, to the device manufacturer and/or the Food and Drug Administration (FDA).
- Selecting departmental staff and training them to perform their functions in a professional manner
- Establishing departmental priorities, developing and enforcing departmental policies and procedures, and supervising and directing departmental activities. The clinical engineering director takes an active role in leading the department to achieve its overall technical goals.

Therefore, the core functions of a clinical engineering department can be summarized as follows:

1. Technology management
2. Risk management

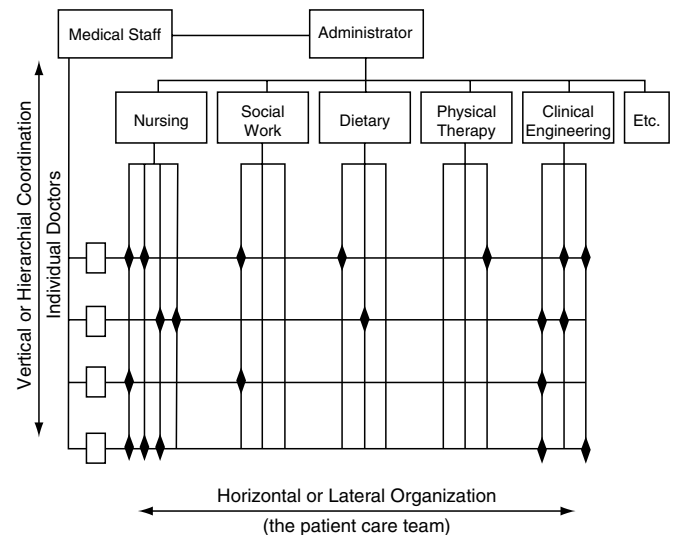

Figure 1-3 Matrix diagram illustrating the bi-directional interdependence and degree of teamwork required to maintain effective interaction between the members of the health care delivery team.

3. Technology assessment
4. Facilities design and project management
5. Quality assurance
6. Training

Professional Status of Clinical Engineering

Upon careful review of our definition of clinical engineering and the responsibilities and functions that clinical engineers assume within the hospital, it is clear that the term

clinical engineer must be associated with individuals who can provide engineering services, not simply technical services. Clinical engineers, therefore, must be individuals who have a minimum of a four-year bachelor's degree in an engineering discipline. They must be well versed in the design, modification, and testing of medical instrumentation—skills that fall predominantly in the field of engineering practice. Only with an engineering background can clinical engineers assume their proper role working with other health professionals to use available technological resources effectively and to improve health care delivery.

By clearly linking clinical engineering to the engineering profession, a number of important objectives are achieved. First, it enables hospital administrators to identify qualified individuals to serve as clinical engineers within their institutions and to understand better the wide range of functions that clinical engineers can perform, while making it clear that technicians cannot assume this role. Second, from this foundation, it is possible for the profession of clinical engineering to continue to mature. It has been pointed out that professional activities exist if "a cluster of roles in which the incumbents perform certain functions valued in the society in general" can be identified (Parsons, 1954; Courter, 1980; Goodman, 1989). Clearly, this goal has been achieved for the clinical engineer.

One can determine the status of professionalization by noting the occurrence of six crucial events: (1) the first training school; (2) the first university school; (3) the first local professional association; (4) the first national professional association; (5) the first state license law; and (6) the first formal code of ethics (Wilensky, 1964; Goodman, 1989).

Now let us consider the present status of professionalism of clinical engineering. Consider the following: (1) there is continued discussion about the educational needs of existing, as well as beginning, professionals; (2) there is a professional society, the American College of Clinical Engineering, which is effective in establishing the knowledge base on which the profession is to develop; (3) there exists a credentials process that reflects the needs of this new profession; and (4) there is a code of ethics, which the American College of Clinical Engineering has developed for use by all in the profession.

This process toward professionalization will certainly continue in the years ahead as this new professional society continues to seek to define and control certification activities, to define the educational process that is required for these new professionals, and to promote the status of clinical engineering to hospital administrators and society as a whole.

Future of Clinical Engineering

From its early days—when electrical safety testing and basic preventive maintenance were the primary concerns—to the present, the practice of clinical engineering has changed enormously. Yet, it is appropriate to use the cliché, "The more things change, the more they stay the same." Today, hospital-based clinical engineers still have the following as their primary concerns: patient safety and good hospital equipment management. However, these basic concerns are being supplemented by new areas of responsibility, making the clinical engineer not only the chief technology officer but also an integral part of the hospital management team.

In large part, these demands are due to the economic pressures that hospitals face. State-of-the-art, highly complex instruments, such as MRI systems, surgical lasers, and other sophisticated devices, are now used as a matter of course in patient care. Because of the high cost and complexity of such instrumentation, the institution needs to plan carefully—at both a technical and a managerial level—for the assessment, acquisition, and use of this new technology.

With these needs in mind, hospital administrators have begun to turn to their clinical engineering staffs for assistance in operational areas. Clinical engineers now provide assistance in the application and management of many other technologies that support patient care (e.g., computer support, telecommunications, facilities operations, and strategic planning).

Computer Support

The use of personal computers (PCs) has grown enormously in the past decade. PCs are now commonplace in every facet of hospital operations, including data analysis for research, use as a teaching tool, and many administrative tasks. PCs are also increasingly used as integral parts of local area networks (LANs) and hospital information systems.

Because of their technical training and experience with computerized patient record systems and inventory and equipment management programs, many clinical engineers have extended their scope of activities to include personal computer support. In the process, the hospital has accrued several benefits from this involvement of clinical engineering in computer servicing. The first is time: Whenever computers are used in direct clinical applications or in administrative work, downtime is expensive. In-house servicing can provide faster and often more dependable repairs than an outside group can. Second, with in-house service, there is no need to send a computer out for service, thus reducing the possibility that computer equipment will be damaged or lost. Finally, in-house service reduces costs by permitting the hospital to avoid expensive service contracts for computers and peripheral equipment.

With all of these benefits, it might seem that every clinical engineering department should carry out computer servicing. However, the picture is not so simple. At the most basic level, the clinical engineering program must be sure that it has the staff, money, and space to do the job well. To assist in making this determination, several questions should be asked: Will computer repair take too much time away from the department's primary goal of patient care instrumentation? Is there enough money and space to stock needed parts, replacement boards, diagnostic software, and peripheral devices? For those hospitals that do commit the resources needed to support computer repair, clinical engineers have found that their departments can provide these services very efficiently, and they subsequently receive added recognition and visibility within the hospital.

Telecommunications

Another area of increased clinical engineering involvement is hospital-based telecommunications. In the modern health care institution, telecommunications covers many important activities, the most visible of which is telephone service. Broadly speaking, however, telecommunications today includes many other capabilities.

Until the 1970s, telephone systems were basically electromechanical, using switches, relays, and other analog circuitry. During the 1970s, digital equipment began to appear. This development allowed the introduction of innovations such as touch tone dialing, call forwarding, conference calling, improved call transferring, and other advanced services. The breakup of the Bell System also changed the telecommunications field enormously by opening it to competition and diversification of services.

Data transmission capability allows the hospital to send scans and reports to physicians at their offices or at other remote locations. Data, such as patient ECGs, can be transmitted from the hospital to a data analysis system at another location, and the results can be transmitted back. Hospitals are also making increased use of facsimile (fax) transmission. This equipment allows documents, such as patient charts, to be sent via telephone line from a remote location and reconstructed at the receiving site in a matter of minutes.

Modern telecommunications equipment also allows the hospital to conduct educational conferences through microwave links that allow video transmission of a conference taking place at a separate site. Some newer equipment allows pictorial information, such as patient slides, to be digitally transmitted via a phone line and then electronically reassembled to produce a video image.

Clinical engineers can play an important role in helping the hospital administrators to develop plans for a continually evolving telecommunications system. They can provide technical support during the planning stage, can assist in the development of requests for proposals for a new system, and can help to resolve any physical plant issues associated with installing the new system. Thereafter, the clinical engineer can assist in reviewing responses to the hospital's requests for quotations and can lend a hand during installation of the system.

Facilities Operations

Recently, some hospital administrators have begun to tap the high-level technical skills that are available within their clinical engineering departments to assist in other operational areas. One of these is facilities operations, which includes heating, ventilation, and air conditioning (HVAC), electrical supply and distribution (including isolated power), central gas supply and vacuum systems, and other physical plant equipment (Newhouse et al., 1989). This trend has occurred for a number of reasons. First, the modern physical plant contains microprocessor-driven control circuits, sophisticated circuitry, and other high-level technology. In many instances, facilities personnel lack the necessary training to understand the engineering theory underlying these systems. Thus, clinical engineers can effectively work in a consultation role to help correct malfunctions in the hospital's physical plant systems. Another reason is cost; the hospital might be able to avoid expensive service contracts by performing this work in-house.

Clinical engineers can assist in facilities operations in other ways. For example, they can lend assistance when compressed gas or vacuum delivery systems need to be upgraded or replaced. While the work is taking place, the clinical engineer can serve as the administration's technical arm, ensuring that the job is done properly, that it is in compliance with code, and that it is done with minimal disruption.

Strategic Planning

Today's emphasis on health care cost control requires that clinical engineers assist in containing costs associated with the use of modern medical technology. To accomplish this objective, clinical engineers are increasingly becoming involved in strategic planning, technology assessment, and purchase review. During assessment and purchase review, the clinical engineer studies a request to buy a new system or device and ensures that the purchase request includes (1) needed accessories; (2) warranty information; and (3) user and service training. This review process ensures that the device is, in fact, needed (or whether there exists a less costly unit that meets the clinician's requirements) and that it will be properly integrated into the hospital's existing equipment and physical environment.

Clinical engineers can provide valuable assistance during the planning for, and financial analysis of, potential new services. If one considers the steps that are involved in planning for a new patient-care area, many design questions immediately come to mind: What is the best layout for the new area? What equipment will be used there? How many suction, air, oxygen, and electrical outlets will be needed? Is there a need to provide for special facilities, such as those that are required for hemodialysis treatment at the bedside? With their knowledge of instrumentation and user needs, clinical engineers can help select reliable, cost-effective equipment to help ensure that the hospital obtains the best possible plan.

In the future, clinical engineering departments will need to concentrate even more heavily on management issues by emphasizing the goals of increased productivity and reduced costs. By continually expanding their horizons, clinical engineers can be major players in ensuring high-quality patient care at a reasonable cost.

Modern medical care is centered upon the use of a broad range of equipment and medical devices, resulting in an increasing demand for workers with technological expertise. This chapter emphasizes the interdependence of medical device technology and those who manage that technology. Highlighting the significant milestones in medical device development over the past century serves to illustrate the increasing symbiotic relationship between medical device technology and those who must support that technology, the clinical engineers, biomedical equipment technicians, physicists, and equipment maintenance personnel.

The Early 1900s

A minor hospital building boom significantly increased the number of hospitals in the United States. However, the principal means of providing health care was still physicians making house calls and carrying their "little black bags." In general, physicians seemed to be in short supply, but so was the demand for their services. Many of the services that the physician provided also could be obtained from experienced amateurs in the community. The home was typically the site for treatment and recuperation, and relatives and neighbors constituted an able and willing nursing staff. At the time, the average life expectancy was 47 years, and 95% of all births were in the home, although only 15% of the homes had a bathtub. The leading causes of death were pneumonia, influenza, tuberculosis, and dysentery, followed by heart disease and stroke.

The first X-ray machines were introduced following Roentgen's discovery of X rays in 1895. Early radiographs involved large doses of radiation. An image of the human head could require up to 11 minutes of exposure time. The first use of contrast media occurred between 1906 and 1912. Dutch physiologist Willem Einthoven introduced the first ECG recording device, a string galvanometer, in 1901. Because it used a very large magnet, it was large and heavy, weighing about 600 lbs. The first "telegardiogram" was recorded on

March 22, 1905, when Einthoven transmitted ECG signals from a healthy volunteer in a hospital to the galvanometer in his laboratory, 1.5 kilometers away by way of pole-mounted telephone cables. The volunteer's elevated R-waves were attributed to his cycling from the laboratory to the hospital for the recording. The latest technology at that time was the radio which, following Marconi's first successful transmissions in 1895, was used primarily for ship-to-ship communications.

Pre-1940

During the period between World Wars I and II (1919-1939), the development of medical instrumentation benefited from electronic amplification and the adaptation of technologies that had been developed for other applications.

The use of X rays for diagnosis continued to progress during this period, as did the use of radium needles for the treatment of tumors. Hospitals where radiation treatments were performed began to employ physicists to assist in the treatment planning and safe use of the radiation sources. The development of instruments and devices for diagnosis or medical research was generally undertaken through the collaboration of physicians and private entrepreneurs.

The use of electronic amplification techniques developed following Lee de Forest's invention of the triode valve in 1906 led to more compact ECG machines. Sanborn and Cambridge Instruments were early manufacturers of these table- or cart-mounted devices. In 1928, Frank Sanborn's company (later acquired by Hewlett-Packard) converted its table model ECG machine into its first portable version, which weighed 50 lbs. and was powered by a six-volt automobile battery. Al Grass contributed to the development of electroencephalography by adapting a low-frequency, high-gain recorder that he had first used to monitor seismic events to charting very small EEG potentials. Arnold Beckman adapted a pH-sensing electrode, which he had developed as a "ripeness indicator" for the

citrus industry in southern California, to medical uses in the clinical laboratory. In a slightly different type of collaboration, W.T. Bovie, a physicist employed by the Harvard Cancer Clinic, developed a spark-gap electro-surgical machine that was first used in 1925 by prominent neurosurgeon Harvey Cushing.

Other medical devices commonly found at that time in the hospital included instrument sterilizers and, after 1927, large pressure chamber-type respirators known as “iron lungs” that were used to keep chest-paralyzed polio patients alive. The inventors, Harvard medical researchers Philip Drinker and Louis Shaw, used an iron box and two vacuum cleaners to create the device, which was about the length of a subcompact car. At that time, maintenance of these devices was largely in the hands of the facility’s on-site plant engineer and the equipment manufacturer. The United States army had one of the first centrally managed groups of hospitals and was certainly the first on record to take an intelligent interest in maintaining its equipment. On July 11, 1919, the surgeon general of the army sent a letter to the quartermaster general stating:

“It is believed to be better policy to have a central repair establishment in the medical department to which surgical instruments and delicate laboratory equipment can be sent for repairs.”

In 1922, the army established a central maintenance facility at its St. Louis Medical Depot, presumably to provide a more proficient capability to repair the more delicate instruments. Later, during the early years of World War II, the army’s hospital managers recognized a need for an organized training program, and on January 10, 1943, the surgeon general authorized a three-month biomedical equipment technician training course and requested the adjutant general to publish quotas for a school to be conducted at the St. Louis Medical Depot. This was the beginning of the army’s Biomedical Equipment Training Program, the first such program in the United States with the requirement to cover a wide variety of medical equipment.

In 1918, a worldwide flu epidemic killed 20 million people, including 500,000 Americans. The battle against infectious diseases was aided considerably during the latter part of this period by the development in Germany of the sulfa class of drugs, which became the first pharmaceutical tools for use against infectious diseases. Although British bacteriologist Alexander Fleming discovered penicillin in 1928, that drug’s potential for use as an antibiotic was not immediately recognized, and the drug was not produced in quantity and made generally available until after World War II. The passage of the Food, Drug and Cosmetic Act in 1938 initiated the requirement that all drugs be approved by the FDA prior to being marketed in the United States.

The 1940s and 1950s

The post-World War II years (1945–1959) can be described best as the “golden age of medical electronics.” Innovation was spurred by new technologies that had been developed for military applications and by medical electronics advances that had been pioneered in university-based research-and-development (R&D) labs. The teaching hospital-based model shops, often associated with a medical physics department, collaborated with creative, research-oriented physicians to develop many new aids and began to expand their area of interest beyond mechanical gadgets and toward electronic devices.

In 1947, the Hill-Burton Act ignited another hospital building boom. Over the next 25 years, the federal government subsidized state building programs with more than \$3.7 billion. Hospital budgets were also fattened by a growing number of employer-paid group insurance programs. The first group program was provided by the Montgomery Ward retail chain in 1910, and the first Blue Cross plan was established for municipal employees in Dallas in 1929.

Several new, military-developed technologies provided a boost to this new area of medical electronics. Anti-submarine sonar countermeasures gave birth in Japan to A-scan ultrasound, and the development of microwave radar technology accelerated the formation of innovative electronic design teams in the U.S. McGraw-Hill published a series of textbooks called the *Radiation Laboratory* series, in which many clever pulse, waveform, and amplifier circuits were described.

In the larger medical institutions, medical physics departments were staffed by physicists and technicians who assisted with radiotherapy and dispensing isotopes for both therapy and treatment. In these departments, small R&D groups were formed to assist research-oriented physicians with the fabrication of specialized research tools. Initially, these R&D projects were mechanically oriented, with some of these efforts resulting in successful prototypes of devices such as dialysis machines and artificial heart valves. During the post-war years, these groups diversified into electronic gadgeteering, focusing at first on recording bioelectric signals such as nerve- and muscle-action potentials, and then analyzing them using various electronic techniques. Interesting work was published on topics such as vectorcardiography and ballistocardiography. In 1950, at the University of Manitoba in Canada, electrical engineer John Hopps unexpectedly invented the first external cardiac pacemaker while conducting research on hyperthermia and experimenting with radio-frequency heating to restore body temperature.

In time, more advanced technology allowed for the development of instrumentation to study intracellular activity. Publication of these designs further stimulated this activity and resulted in a small commercial market. Grundfest was known for his physiological amplifier that was fabricated on a Plexiglas chassis to minimize ground currents and suspended by springs to minimize microphonics. Tony Bak marketed a negative capacitance, unity gain microelectrode amplifier as well as glass microelectrodes (micropipettes). Earl Sandbek began marketing ear oximeters, hand-machined and -wired in his home basement shop. Harry Johnson produced a two-beam oscilloscope using Dumont’s pioneer two-gun cathode ray tube, the first such oscilloscope available other than Dumont’s until Tektronix introduced its Model 565, which is still a research staple today.

On the diagnostic imaging side, the subspecialty of angiography followed the introduction of the first image intensifier and the cut-film changer around 1955. Radionuclide scanning, the precursor to nuclear medicine, was first performed during the 1950s using special gamma cameras.

The prestigious Institute for Radio Engineers (IRE) which had formed special-interest groups to address such diverse applications as antennas, audio, and microwaves, formed a Professional Group on Medical Electronics and, in collaboration with the Instrument Society of America, initiated a regular series of annual conferences in 1948. The 1958 Conference on the Topic of Computers in Medicine and Biology drew more than 300 attendees to hear more than 70 papers. In 1961, the attendance exceeded 3000, and over 250 papers were presented. At the 1968 conference, 478 abstracts were presented. The multisociety Alliance that organized these meetings also published detailed proceedings that helped to disseminate this information further.

New leadership sprang up in the electrical engineering departments of many academic centers. One particularly noteworthy example was R. Stuart Mackay, a professor of electrical engineering at the University of California at Berkeley who, in 1951, established an R&D laboratory at what is now the University of California San Francisco Medical Center. He was primarily responsible for a prolific series of advances in electron microscopy, medical telemetry, closed-chest ventricular fibrillation, guard-ring tonometry, the application of ultrasound to the study of diver decompression, and early work on color displays for X-ray information.

On the therapeutic side, Dutch physician Willem Kolff introduced the first artificial organ (an artificial kidney) at the end of World War II. Kolff had developed the prototype units in his native land during the time of German occupation, using readily available natural sausage skins as the dialyzing membrane. At this time, the first organ transplants were being performed, and the surgical teams were wrestling with the practical nursing difficulties that resulted from the need to virtually destroy the body’s natural immune system, leaving a “defenseless” patient who needed to be kept in near-total aseptic isolation. Interestingly, one of the earliest forms of patient monitoring was the “barrier nursing” systems that were constructed during this period to enable the nursing staff to measure the standard bedside indicators of temperature, pulse rate, and respiration from the nonsterile side of a window in the isolation barrier.

In 1948, Brattain and Bardeen, working under William Shockley at Bell Labs, codiscovered the physical phenomenon that led to the development of the transistor. In 1951, the Joint Commission on Accreditation of Hospitals (JCAH), the predecessor to today’s JCAHO, was established. In 1955, Jonas Salk’s oral vaccine for poliomyelitis became generally available, as did the birth-control pill. The first patient was treated using a heart-lung machine. Cournand, Richards, and Forssman shared a Nobel Prize in 1956 for their contributions to the advancement of cardiac catheterization. Werner Forssman had passed a urological catheter from a vein in his right arm into his right atrium when he was a surgical intern in 1929 to first demonstrate the feasibility of this technique. In 1956, heart-lung bypass technology received a significant boost with the development of the membrane oxygenator, which allowed extracorporeal circulation of the blood for days, or even weeks, without toxicity or hemolysis. In 1958, physician-engineer Forrest Bird introduced his Universal Medical Respirator, a little, green box known far and wide as “the Bird.” It was the world’s first highly reliable, low-cost, mass-produced medical respirator. The “Baby Bird” respirator, introduced in 1970, would quickly reduce worldwide mortality for babies with respiratory problems from 70% to 10%.

The 1960s

During the 1960s, the era of the first “medical arms race,” hospitals scrambled to be the first to have the most glamorous new equipment and could not get enough of it. The amazing promise of transistorized electronics ignited research into a whole new range of medical devices. Dr. William Chardack, assisted by electrical engineer Wilson Greatbatch, implanted the first internal cardiac pacemaker. The battery life for these early units was only 12–18 months. Other, well publicized “medical marvels” included ingestible endoradiosondes that radioed diagnostic information from the human alimentary tract and fetal heart monitors that promised to reduce or eliminate many of the risks to the unborn child. In 1964, Dr. Bernard Lown introduced the DC defibrillator to replace the less effective AC defibrillator that first had been used by Zoll in 1956.

In 1961, the nation’s growing “Medical Technology Imperative” was given a boost by President John F. Kennedy’s call for the U.S. to put a man on the moon before the end of the decade. Creation of a federally funded (National Heart Institute) Artificial Heart program in 1964 drew upon the strong technological capabilities of the nation’s aerospace contractors. Controversy over the relative promise of artificial organs and transplanted organs continued long after this funding was cut off in the 1980s.

Initiation of the federally funded National Institutes of Health Program of Grants to Universities for Biomedical Engineering Training in 1965 was supplemented by a series of nationwide conferences on a wide variety of biomedical engineering topics such as “multiphasic screening, sponsored by the National Academy of Engineering (NAE). During this period, there was also a considerable amount of activity in many academic centers in areas more related to biophysics and biomathematics. The leaders of this research often had credentials in medicine as well as engineering. According to articles written at the time, there were more than 255 biomedical engineering projects that were supported by research grants from the National Institutes of Health. The Institute of Radio Engineers (IRE) changed the name of the Professional Group on Medical Electronics (PGME) to the Professional Group on Biomedical Engineering (PGBME).

The specialty of clinical engineering arose in the late sixties. It was intended to differentiate the new device safety-related activities from the maintenance and repair activities of in-house biomedical engineering groups.

At this time an amazingly broad range of projects was underway in in-house biomedical engineering R&D laboratories. The contents of a textbook on advances in biomedical engineering, published in 1967, listed such diverse topics as lasers in medicine, dialyzers, hyperbaric oxygen therapy, cardiopulmonary resuscitation, cryogenic surgery, orthopedic prostheses, silicone encapsulation for implants, heart valves, pacemakers, echocardiography, medical telemetry, medical thermography, fiber-optics for endoscopes, fetal heart monitoring, and medical computing. In-house biomedical engineering groups were also beginning to provide limited, on-request, maintenance services for many of the items in

the proliferating inventories of medical instruments. They did not provide the elaborate documentation of these services that would be required later. Some in-house groups even provided repair services to equipment manufacturers.

The first multichannel clinical laboratory analyzers provided the opportunity for the hospital to profit from a medical device. Marketing materials provided with the equipment encouraged hospitals to invite the local press to witness and videotape the fascinating technology of bubbles moving through the multiple glass tubes of the new Technicon multichannel auto analyzers. This footage of a medical marvel would then be presented on the local six o'clock news. The financial arrangements were also attractively structured, in a manner similar to a Coke machine lease. The hospital paid for the analyzer on a simple pay-per-use basis and added a fee to guarantee excellent profitability. The more tests the hospital did, the more money the hospital made!

In 1968, the nation's first investor-owned hospital was opened in Nashville by the Hospital Corporation of America (HCA), the company that eventually, under the leadership of Rick Scott, would own more than 800 of the nation's hospitals. Other for-profit hospital companies soon followed HCA's lead. Other events taking place in the background during this period included the following:

- 1964: Dr. Michael DeBakey performed the first coronary artery bypass (CAB) operation
- Mid-to-late 60s: Preliminary work was already being performed on the risk of fibrillation to patients undergoing cardiac catheterization
- 1967: Christian Barnard performed the first human whole-heart transplant in Cape Town, South Africa.
- 1968: Dr. Denton Cooley implanted a short-lived, non-FDA-approved artificial heart.
- 1969: A four-university network of large computers, known as the Advanced Research Projects Area Net (Arpanet) was created by the Department of Defense. This would later expand and develop into the Internet.

The 1970s

Around the beginning of the 1970s, an ingenious and plausible, but only theoretical, electrical safety scare jump-started a new specialty called "clinical engineering." AAMI had already established a certification program for biomedical equipment technicians in 1970 and in response to these widely publicized electrical safety concerns, decided in 1973 to create a similar certification program for this new type of specialist who was being called a "clinical engineer."

Community hospitals boomed during this period. The number of hospitals across the nation peaked during this decade at 5875, about 16% higher than the number of hospitals existing today. There was a concerted effort to establish networks of specially equipped trauma centers in the major metropolitan areas. There also was growing concern about the runaway cost of health care and a variety of new restraining concepts were introduced, including Regional Medical Programs (RMPs), Certificate of Need (CON) requirements, and the increasing use of Health Maintenance Organizations (HMOs).

A series of professional meetings was held to discuss increasing concern about the theoretical possibility that catheterized patients who have external pacing leads or other conductive pathways directly to the inner wall of the heart are, theoretically at least, vulnerable to potentially lethal ventricular fibrillation induced by the very small "leakage" currents that are sometimes present in the various pieces of equipment that often surround them in the intensive care areas of the hospital. Consumer activist Ralph Nader dramatically described this possibility in an article in the 1971 issue of the *Ladies Home Journal*. He quoted several authoritative sources from the various preceding professional meetings, but in the article extended Dr. Carl Walter's original estimate of the number of deaths per year actually occurring from this theoretical scenario from 1200 to 5000.

Largely as a result of this adverse publicity, a proposal to amend the National Electric Code was presented at the Annual Meeting of the National Fire Protection Association (NFPA) in San Francisco in 1972. This proposal would have required that all power provided within a health care facility be provided by way of special, expensive isolated power systems (IPSS). The proposal is voted down in a dramatic showdown on the floor of the meeting after a concerted effort was made to rally opposition to the proposal by a coalition of representatives of the American Hospital Association, the staff of the newly active, not-for-profit Emergency Care Research Institute (ECRI), and a few biomedical engineers from several large teaching hospitals. The intense debate about the real value of isolated power systems would drag on for six or seven more years before it was finally laid to rest by a ruling from the board of directors of the NFPA. In the meantime the originally-thought-to-be-vulnerable catheterized patients were effectively protected by the simple expedient of shielding the exposed ends of the external conductors. A byproduct of this episode, however, was the discovery that the existing quality of the maintenance of the typical hospital's continually expanding inventory of electronic equipment was inadequate. As a result, a new high-intensity focus on equipment maintenance and safety checking was born.

Although the electrical safety scare was quickly shown to be only theoretical, new regulations addressing this potential threat appeared. In 1974, the JCAH issued new standards that prescribed quarterly documented electrical safety tests for all of the facility's patient care equipment. In California, the Department of Health issued new requirements as part of its new Title 22 regulations introducing the soon-to-be-obsolete concept of the "electrically susceptible" patient, and a host of related tests. Several other jurisdictions followed suit. The California regulation and many of the others created at that time persist today and are still enforced in only slightly modified form. This issue created the new specialty of documented electrical safety testing which, in turn, led to the establishment of several new independent biomedical service organizations.

This same issue did not immediately lead to the widespread creation of more in-house biomedical engineering groups in the smaller hospitals, but it did prompt the W.K. Kellogg Foundation to award a series of seed money grants which over the next five or six years resulted in the formation of about 20 not-for-profit clinical engineering shared

service programs. The shared service concept is based on time sharing a critical mass of trained technical staff among a geographical cluster of the smaller community hospitals that otherwise would not be able to afford an onsite technical capability.

The 1970s also saw the beginning of the widespread introduction of the so-called high-tech (i.e., digital, computer-controlled) medical devices. Tomographic scanning had been a part of basic nuclear medicine for some time when the British company EMI introduced the first commercial tomographic scanners for radiography in 1972. Gordon Hounsfield's original computed tomography (CT) scan took hours to acquire a single slice of image data and more than 24 hours to reconstruct these data back into a single image. CT scanners were quickly recognized as an enormous step forward in the area of radiographic imaging and by 1977, when the General Electric Company introduced its line of CT scanners, every hospital wanted one, in spite of the \$1 million-plus price tag.

Other examples of new technologies that were being incorporated in a more or less continuous stream to the hospital's continually expanding clinical equipment inventory during this period included anesthesia machines that had been revolutionized by the incorporation of electronic monitors and more reliable vaporizers, more sensitive image intensifiers (developed for use in the jungles of Vietnam) that allowed smaller exposure levels during fluoroscopy examinations, and long-life nuclear batteries for use in implantable cardiac pacemakers.

Other events taking place in the background during this period included the passage in 1973 of the Williams-Steiger Act creating the Occupational Safety and Health Administration (OSHA); the Medical Device Amendments of 1976 to the Food, Drug and Cosmetics Act, which extended the FDA's jurisdiction to medical devices and led to the formation of the Bureau of Medical Devices; and in 1977 the first *in-vitro* fertilization which resulted in the birth of Louise Brown in 1978. The end of this decade also saw the availability of the first commercial, off-the-shelf personal computers.

The 1980s

During the 1980s, the widespread adoption of high-tech medical devices accelerated and collided with increased pressure to control health care costs. In-house programs encounter the outsourcing challenge. A landslide election victory for the Republicans in 1981 signaled a more determined effort to control runaway health care costs, and the federal government introduced the concept of fixed-price reimbursement for Medicare and Medicaid patients. The capitation arrangement used a complex price list that is related to the diagnostic-related group (DRG) associated with the patient's complaint when admitted to the hospital. In spite of this effort health care cost inflation continued and insurance premiums rose by 90% between 1981 and 1984.

Hospitals that had purchased high-tech devices such as CT scanners began to experience "repair-ticket shock" as they had to replace high-cost parts such as array processors. The manufacturers began to push fixed-price, full-service contracts as a way of "insuring" against these financial risks. They typically portrayed the high cost of these contracts as good value relative to the revenue lost when the device goes "down."

U.S. Counseling Services introduced "maintenance insurance" in 1982 as a lower-cost alternative to manufacturer full service contracts. The cost was typically at least 20% less than a comparable manufacturer contract. Similar offerings by other insurance companies quickly follow. This concept would bring about significant changes in the medical equipment-maintenance aftermarket.

The "time and materials" feature of maintenance insurance, which unlocked the user from using the services of a predetermined service provider, also opened up a significant market opportunity for independent (i.e., non-manufacturer) service. Several companies specializing in maintaining the high-cost, high-tech devices – particularly CT scanners – were formed and quickly became nationwide competitors to the manufacturers.

During this period, more and more hospitals followed a general nationwide business trend and turn to "outsourcing" contractors for many of their nonclinical services. A number of service companies began to offer hospitals resident on-site clinical engineering services on a contract basis, which is perceived by existing in-house clinical engineering groups as a significant threat. Methods of measuring and enhancing productivity subsequently became a major topic of discussion at professional meetings.

On another front, growing concerns about the environment gave rise to ever more zealous regulations concerning the possible overexposure of health care workers to workplace chemicals such as ethylene oxide, formaldehyde, and several other disinfecting agents. In California, the passage of Proposition 65 extended this concern to the possible exposure to these substances of communities adjacent to hospitals, and all hospitals were finally driven to installing emissions-control devices on their exhaust fans. In New Jersey, the discovery of used syringes and other discarded injection paraphernalia on a local beach resulted in the Medical Waste Tracking Act of 1988. Even though the beach debris was eventually attributed to illegal drug users, hospitals remained saddled with elaborate and costly requirements for the packaging, transporting, and offsite disposal of their infectious waste.

Most health care providers experienced financial difficulties throughout this decade. HMOs were the exception and were growing in a spectacular manner. Hospital closures reached an all-time peak in 1988, during which 88 hospitals closed their doors. Medical insurance premiums rose again in the four-year period between 1988 and 1992 by 74%. Nevertheless, the pace of medical technology acquisitions continued. Prototype magnetic resonance imaging (MRI) machines, which had been pioneered by Dr. Raymond Damadian, founder of Fonar, were cleared by the FDA and introduced to the hospital marketplace in 1984. They received the same favorable response that CT scanners had received earlier. Other high-tech devices also continued to be well received. Even though the release of Cyclosporin, the anti-rejection wonder drug, in 1983 put new life into the organ transplant programs, the artificial heart program continued. A new model, the Jarvik 7, had been implanted in 1982 by Dr. William DeVries.

In 1985, Dr. Sam Maslak, working with the Acuson Corporation, developed the 128-channel computed sonography platform which quickly became the "gold standard" for a growing list of ultrasound applications. Later advances during the 1990s dramatically improved the quality and diagnostic value of ultrasound images.

The 1990s

In the early 1990s, the American College of Clinical Engineering (ACCE) was founded [see Chapter 130]. It was then, and remains today, the only professional organization devoted solely to representing the interests of clinical engineers. Its mission statement reads as follows:

1. To *establish* a standard of competence and to promote excellence in Clinical Engineering Practice.
2. To *promote* safe and effective application of Science and Technology to patient care.
3. To *define* the body of knowledge on which the profession is based.
4. To *represent* the professional interests of Clinical Engineers.

During the 1990s, hospitals begin to look at information technology and technology management in general, but continued pressure to reduce labor costs eliminated many of the middle managers who would have been instrumental in making these strategic decisions. Marvelous new, but expensive, prescription drugs began to consume even more of the health care budget. Doing more with less continued to be the dominant theme in hospitals.

In 1993, health care reform became an important political issue but the process stumbled badly and the plan conceived by Hillary Clinton, the wife of then-President William Clinton, never came to fruition. Other "political" factors came into play. There is a widespread public outcry against HMO-related denials of service. Many of the alliances among hospitals began to fall apart because of disappointing cost-saving benefits. Erosion of working conditions in stressed hospitals contributed to shortages of skilled staff.

The assimilation of glamorous new technologies such as PET scanners, SPECT scanners, "Gamma Knives," and PACS networks continued unabated. Few hospitals appeared willing to change their past practices and institute realistic technology assessments or to create an authoritative "technology manager" or "chief technology officer." The acceptance of some cost-saving technologies, such as endoscopic surgery and telemedicine, reduced the pressure somewhat.

The general trend to outsourcing continued and was reinforced in the clinical engineering area by Columbia's decision to outsource its large corporate in-house clinical engineering program to GE Medical. Some salesperson in one of the national outsourcing companies coined the indefinable term "asset management" and created yet another level of confusion in the marketplace and the clinical engineering community.

After many years of hostility to independent service organizations based on an assertion that only the manufacturer can adequately service high-tech medical devices, several of the manufacturers of medical imaging equipment declared themselves to be in the "multivendor service" business and offered contracts to service other manufacturers' products.

Significant consolidation took place in the independent service marketplace, resulting in fewer choices in some local areas and regions. Consolidation in the medical equipment manufacturing industry also began to accelerate, reducing the hospital's competitive choices and further diminishing the probability that the manufacturers will be willing to sell parts and technical information to their competitors in the after-sale-maintenance marketplace.

Toward the end of the decade, the prescription-drug manufacturers launch an effective campaign of advertising their new "wonder" drugs directly to the consumer. Their success in this area put further pressure on health care costs.

The FDA expressed concern about the quality of refurbished medical devices and in 1997 issued an advanced notice of proposed rulemaking that reveals some confusion about their understanding of the role of equipment maintainers. It was rumored that this action was precipitated by the equipment manufacturers' desire to further handicap their independent competitors for the after-sale-maintenance business. The FDA stated that it intend to encourage an alternative voluntary registration program that would enable purchasers of used medical devices to clearly differentiate properly restored devices from those in the "spray and pray" category.

The Twenty-First Century

The public's perception of the health care system appears to be at an all-time low. There has been an extended round of whistle-blower suits that have resulted in a number of health care executives being convicted of defrauding the government's Medicare program. The number of Americans who have no medical insurance coverage is at an all-time high in spite of the fact that the nation's expenditures on health care as a percentage of the country's gross domestic product is also at an all-time high. This trend shows absolutely no promise of a change in direction.

The health care industry has recently been rocked by two devastating reports from the Institute of Medicine that are extremely critical of the overall quality of the health care services delivered by the industry, and its failure to date to incorporate modern business methods. Allegations of very high death rates and associated additional costs estimated to be as high as \$29 billion per year resulting from avoidable medical errors are very troubling. At the same time, the public is being bombarded with promises of a medical revolution based on almost unbelievable technological breakthroughs such as diagnostic DNA chips, surgical robots, and a revolutionary, new class of clinical-information systems. The FDA has recently approved a completely self-contained artificial heart that will reportedly cost no more than \$25,000 when manufactured in quantity and an ingestible capsule that will transmit back pictures of the patient's entire, intact digestive system.

While there still are important contributions to make in the traditional areas of medical physics, biophysics, bioengineering, biomedical engineering, clinical engineering, and maintenance of the medical equipment and devices, there are clearly major opportunities to contribute by creating a new specialty area that might be called "clinical systems engineering."

The experts tell us that a large percentage of medical errors occur because the systems that we have in place to deliver the various segments of health care are too complicated. We need help from professionals who have interdisciplinary skills and some kind of training in systems analysis. We also need technology that will simplify these systems rather than make them more complex. Both of these needs seem to represent a major opportunity for the technological disciplines to continue to make significant contributions.

The Health Care Environment

Lee O. Welter

Health Care Consultant
Sacramento, CA

The health care environment can be viewed from multiple perspectives. A historical perspective and philosophical approach improves our sense of intellectual balance and helps us to progress without recreating many mistakes of the past.

A quote from Sir William Osler's *Aequanimitas and Other Addresses* is cited in the preface to Richard Gordon's book, *The Alarming History of Medicine* (Gordon, 1993):

"The philosophies of one age have become the absurdities of the next, and the foolishness of yesterday has become the wisdom of tomorrow, through long ages which were slowly learning what we are hurrying to forget, amid all the changes and chances of twenty-five centuries, the profession has never lacked men who have lived up to the Greek ideals." Despite dramatic changes in the science of medicine, the ethics and art of medicine have been largely sustained.

Ancient and Prehistoric Medicine

Evidence of primitive medical care extends as far back as our knowledge of human existence. Ice-Age cave drawings depicted witch doctors. A body from that era, found frozen in a receding glacier, was carrying pouches of medicinal herbs. Stone Age skulls revealed healed trephine holes (Duin and Sutcliffe, 1992).

King Asoka of Buddhist India, of several centuries BC, established medical schools and hospitals, even a veterinary hospital. Hospitals were first evidenced in ancient Egypt, with this practice later adopted by the Greeks the Romans, whose military hospitals ultimately came to be used for the destitute. A standard of professional ethics that currently applies was developed by Hippocrates, "the father of medicine." In ancient Greece, medical science tended to displace magic and witchcraft. Religion has continued to be a factor in medical practice.

Around 335 AD, the Church and its nursing orders took up this enterprise. Hotel Dieu in Paris, founded in 660 A.D., still survives and reveals architectural attention to vital features such as lighting and ventilation, ease of cleaning, and the placement of patients for ready nursing observation beyond the view of other patients. Early Arabic hospitals provided good nutrition, music, and even storytellers, as well as nurses and physicians. Bladder stones had been surgically treated by the ancient Arabs and Hindus. Due to the lack of adequate anesthesia and perioperative care, these and other surgeries were performed only when urgently needed. Until well into the nineteenth century, such operations were similarly conducted as speedily as possible since only about one third of those patients survived the stress and pain. After general anesthesia came into use, about two-thirds of anesthetized surgery patients survived.

Science Struggles Against Superstition and Tradition

Advocating a scientific basis for medicine, rather than traditional dogma, Roger Bacon, physician and scientist, was not well received by those in power. Among his many ideas was the development of corrective lenses (eyeglasses) to aid persons suffering presbyopia. He envisioned the invention of the powerboat, the flying machine, the mechanical hoist, and the horseless carriage. For his heresy, Bacon was punished by the Dominicans of the Inquisition with imprisonment for nearly the rest of his life. From the mid-fourteenth through the mid-eighteenth centuries, such persecution reigned, finally fading after 1836, when a young woman was drowned for practicing witchcraft. However, the attitudes and underlying human behavior that prompted and condoned these witch hunts have remained part of the human condition.

Social and political issues have remained prominent throughout the ages. Having discovered oxygen, Joseph Priestly had been experimenting with the potential of nitrous oxide gas as an anesthetic approximately a century before it was widely adopted for that purpose. His English neighbors, intolerant of such radical behavior and his unorthodox religious views, torched his home laboratory and forced him to flee in 1791 for the United

States, where he became interested in Benjamin Franklin's experiments with electricity and neglected his medical developments.

Resistance to Change Is Human Nature

Resistance to change remains a constant of human nature. This has been particularly dramatic in the sphere of medicine. One striking example was the English discovery in 1601 of citrus fruit (containing vitamin C) to prevent scurvy, which had been killing the majority aboard long sea voyages. Rediscovered in 1747, this practice was not instituted by the British navy until 1795 and by its merchant marine in 1865. To this day, resistance to change is a factor that must be considered in every attempt to progress in practically every human endeavor.

Science and Humanity Gain Ground on Ignorance and Superstition

During the nineteenth century, the world and its medical domain began its accelerating progress. Treatment of the mentally ill, previously by torture to drive out the evil spirits, gradually became more humane. Johann Peter Frank wrote about the concepts of disease prevention and public health welfare near the beginning of the nineteenth century. Around that time, Edward Jenner fostered the innovation of vaccination to prevent smallpox. Xavier Bichat discovered the tissues of which the body is composed, and he recognized the unique characteristics of physiology. Physical diagnosis was advanced by Leopold Auenbrugger and Jean Nicolas Corvisart, and further extended by Rene Theophile Hyacinthe Laennec's development of the stethoscope and its clinical application.

Public Health versus Contagion

Public health regulations were introduced in Great Britain during the mid-nineteenth century. Dr. John Snow served a dramatic and vital public health need during the 1854 "Broad Street Pump Outbreak" cholera epidemic by identifying a particular public well as an infection source. He broke off the well's handle to prevent its use and published *On the Mode of Communication of Cholera* the following year. Around the same time, New York and Massachusetts made similar public-health and urban-planning recommendations. These initiatives considered fundamental physiologic and psychological needs and protection from contagion and accidents. Many of these recommendations had been advocated over many centuries as essentials for a healthful life.

The inflammatory and infectious nature of many diseases began to be recognized. Ignaz Philipp Semmelweis recognized the contagious basis for puerperal fever and advocated that handwashing by clinicians could largely prevent this deadly scourge. Embarrassed by Semmelweis, his contemporaries terminated his employment. Progress was often not cheerfully received.

Medical Science and Technology Progress Despite Opposition

For example, in the last half of that century, even though adequate anesthesia was available for surgery, some surgery continued to be performed without it. When Harvey Cushing advocated the routine use of blood-pressure measurement during anesthesia and surgery, the Harvard Medical School study committee concluded that it was unnecessary. Fortunately, anesthesia practitioners readily adopted Cushing's innovation. Other medical technology, such as the microscope, permitted further research and advances. Louis Pasteur discovered the existence of cells and developed the germ theory of disease. Joseph Lister extended this theory into the practice of antiseptics for surgery, acknowledging Semmelweis's contribution. Johannes Mueller, a professor at Berlin's University, promoted extensive medical research, encouraging many others to pursue such development in physiology, histology, pathology, the extensive application of the microscope, and the invention of the ophthalmoscope. His colleagues and successors advanced the scientific basis of medicine. From there, later devices such as the electron microscope and

recording kymograph permitted advances in laboratory and medical science. Ultimately, the disciplines of genetics, immunology, antibiotic and pharmaceutical therapy, endocrinology, neurophysiology, neurology, and psychiatry evolved.

Special surgical tools represent the earliest medical instruments. Their initially primitive nature was matched by the relative crudeness and poor success of early surgery, which had prompted physicians to distance themselves from the practitioners of surgery. This gap between physicians (i.e., internal medicine) and surgeons gradually dissolved as the science and accomplishments of surgery advanced.

By the early nineteenth century, thermometers, anesthesia and blood pressure measurement devices, surgical instruments and furniture, and sterilizers were in use. More complex instruments such as the electrocardiograph were developed and gradually introduced to clinical practice. The finger-on-the-pulse technique was extended by devices for measuring and for displaying the pulse wave-form. Refined microscopes and further laboratory measurement techniques promoted the development of clinical pathology and laboratory medicine. The power and importance of accurate, reliable medical instruments was emphasized in an 1890 *JAMA* editorial: "successful medical practice (requires) precision in diagnosis," which is dependent upon medical instruments. Instruments that were not easy to use did not become popular.

Hospitals Become Medical Technology Resources

Another powerful innovation evolved as progress in their science led surgeons to be accorded equal status to physicians (internists). Rather than remaining merely a place for sick people waiting to die, the hospital became a focus of medical technology and increasingly specialized practitioners. Joel D. Howell's book, *Technology in the Hospital – Transforming Patient Care in the Early Twentieth Century*, offers the following examples and comments (Howell, 1995). An apparently healthy patient with a broken leg was seen at the Pennsylvania Hospital in 1900, but no X ray was done, and the only laboratory test was a cursory urinalysis. Fifty-one days later, he was "cured" and left the hospital. His entire hospital record was a single page. About 25 years later, a similar patient required a hospital stay of only 21 days, but received an X-ray diagnosis and four urinalyses, and grew a chart eight pages long. This transformation in care is attributed to a greater belief in the scientific basis of medical practice and an attendant faith in objective data. In part, it reflected a greater social acceptance of the hospital's role in medical care.

Wilhelm Roentgen first described X-ray images in 1895, the same year that Frederick W. Taylor first published his writings about scientific management. Hospitals came to be recognized as candidates for the same improved management and information-handling systems as other businesses. Increasing patient loads led physicians to begin expecting payment for their hospital care. Hospitals also devised accounting methods.

Medical Informatics Is Initiated

Advances in hospital organization promoted such advances and triggered new ideas. Boston surgeon, Ernest Amory Codman, Harvey Cushing's medical school colleague, argued for outcomes studies to improve surgical management. Dr. John Shaw Billings, physician director of the Army Surgeon General's Library (later the National Library of Medicine) assisted with the 1880 and 1890 census. He encouraged Herman Hollerith to develop a machine for tabulating population and similar statistics. Invented in 1882, these machines processed the data for 62 million people in the 1890 census. Calculators and then Hollerith card systems were used initially in 1887 for health and vital statistics in Baltimore and New York City; then by the Surgeon General's Office. Hospitals began using this system for accounting and clinical data. Hollerith's Tabulating Machines company, started in 1886, later became International Business Machines (IBM).

Concurrently, the length and complexity of patient charts grew, with increased specialization and departmentalization leading to fragmented, discontinuous records. Subsequently, careful design of specialized forms and charts was undertaken. Other infrastructure improvements improved the availability of medical care: Improved transportation has permitted doctors to see ten times as many patients as they could 80 years ago. The patients could now travel to the doctor (or hospital) rather than requiring the doctor to travel to the patients.

During the 1920s, life insurance companies began using blood pressure, spirometry, urinalysis, to supplement traditional medical assessments of risk. Standards were developed for such measurements and for the differentiation of normal-versus-abnormal values. The importance of precise measurement and documentation became recognized, and the concept of self care was promoted. The environmental and industrial contributions to disease gained recognition.

Medical and Hospital Management Evolve

The Mayo Clinic and Hospitals, in Rochester, Minnesota, which were founded in the late 1880s by Dr. William Worall Mayo and his two sons, became a prototype multispecialty clinic. Its fame is well deserved, with many firsts to its credit, including iodine treatment for goiter, the first blood bank, and the discovery of cortisone. Among other successes, it emphasizes quality of nursing care as well as educational programs for its staff.

The most dramatic changes occurred in surgery, for which hospital developments created an apt environment that internists also adopted. Even though medical care and surgery still could have been provided in patients' homes, hospitals provided good electric lighting and specialized equipment, as well as trained staff. These improvements promoted an increase in the volume of surgery. For example, tonsillectomy could be justified, sometimes "just because the tonsils were there."

Management guru Peter Drucker recognizes that, despite its shortcomings, the evolving hospital organization itself was an innovation that improved medical care (Drucker, 1980). The Great Depression gave management, or business management, a negative connotation, so that Raymond Sloan's study of hospital management led to the discipline called *hospital administration*. Drucker notes that the science of management cuts across

every enterprise (Drucker, 1999). He sees favorable evolution in this discipline, as outlined below.

Cost and Quality Issues Arise

During the 1930s, health care accounted for about 1% of the gross domestic product (GDP) in the United States; today that figure is about 15%. The hospitals of the 1940s were very labor-intensive, but hospitals now have tremendous investment in expensive high-tech equipment as well. They have become capital-intensive, but specialized personnel are needed to operate and manage these systems. Concentration on special skills is essential for performance improvement, but "only massive increases in hospital productivity can stem the health care cost explosion."

The United States' National Academy of Sciences publication, *Organizational Linkages – The Productivity Paradox*, examines the lack of improved productivity commensurate with the massive expenditures on information technology (IT) in the late twentieth century (Harris, 1994). One of its conclusions is that operations improvement is the most effective IT benefit. The greatest opportunity for this in medicine lies in streamlining the capture of data and in providing timely, relevant information to aid decisions at the point of care.

Medical care's focus upon fighting disease is shifting to the maintenance of physical and mental health. Accompanying this is a shift in emphasis on information technology from the technology to the information. The site of care is increasingly migrating outside of hospital walls.

Historically, our current Information Revolution is the most recent of four. The first was the invention of writing in Mesopotamia, more than 5000 years ago. The second was the invention of the written book in China, around 1300 BC, and in Greece, around 500 BC. The third, between 1450 and 1455, was the adoption of the printing press, engraving, and movable type.

Drucker's observations above are fascinating, but they neglect to mention one important factor. A popular assumption is that improving medical capabilities and quality must lead to increasing costs. Even though medical innovation may account for about a third of the large increase in the United States' medical expenditures, another major factor has not been realistically addressed.

Economic Consequences of Regulation and Good Intentions

During World War II, the U.S. Government imposed wage controls in an attempt to counteract the market forces of high labor demand and low supply. One loophole was that fringe benefits were not limited. Consequently, the practice of employer-provided prepaid medical benefits (with favored tax treatment) became widespread. Patients and doctors were consequently freed from cost constraints in delivering medical care. The inevitable economic consequences were only accelerated in the mid-1960s, when the introduction of Medicare and Medicaid further severed the direct link between consumption and payment.

Economic laws of supply and demand cannot be repealed; rationing is the alternative when price controls prevent supply from increasing in response to demand. This fundamental issue is still not being addressed realistically. In the United States, government and corporate payment intermediaries have been using clumsy forms of rationing since the mid-1980s. Regardless of the specific payment mechanisms, improved costs as well as improved quality must both continue to be sought because available resources are finite.

The Need for Modern Management

The lack of cost constraints had other adverse consequences. V. Clayton Sherman, a hospital management consultant, prefaces his book (Sherman, 1999): "in the early 1980s . . . Health care as an industry was in a time warp, notably behind the advance of the management profession and seemingly oblivious to its direction. . . . we're still catching up to the state of the management art. . . ." Unlike the growth era of the medical device industry from 1965 to 1976, current constraints, beginning in 1983 with limited payments, require new devices to improve costs and quality.

Some such constructive movements have already commenced. Hospitals and other businesses are "unbundling" noncore services. Outsourcing of noncore services is beneficial: The contractor can specialize, develop superior performance, and provide suitable career ladders for its employees. More clinical or core services are also being contracted. These include contracts with physician multi- and single-specialty groups, perfusion services, clinical engineering, and turnkey infusion systems.

Drucker writes, "innovation matters because ours is a knowledge-based society," and health care is heavily dependent upon information management (Drucker, 1999). His example of innovative hospital reengineering is that some hospitals are managing patients as they would emergency patients (who are unable to fill out lengthy forms) – eliminating most of the laborious and expensive admissions process.

Drucker notes that in order to increase knowledge-work productivity, the questions to ask are the following: "What is the task? What do we try to accomplish? Why do it at all?" The answers permit redefining the task and eliminating unnecessary work. Drucker credits the late Karl Bays, who made American Hospital Supply (later acquired by Baxter Labs) the industry leader in the 1970s by listening to customers and determining their needs.

Some institutions have already undertaken such efforts. American hospitals' claim of a "nursing shortage" ignores that over half of the nurses' time is spent with non-nursing tasks, such as paperwork for third-party payors. Some are relegating such tasks to ancillary personnel and are applying appropriate technology.

Medical Informatics Continues to Evolve

Gerhard Venzmer envisioned future extensions of medical informatics based upon his observation that ". . . in the Mayo Clinic . . . case histories of patients are . . . electroni-

cally assessed. . . . such a vast amount of data—there are forty thousand different diseases—that no doctor in the world could keep all their symptoms in his head (Venzmer, 1968). The computer, however, stores them all up.”

Dr. Morris Collen sketches the recent development of computer-based medical informatics (Collen, 1995). In 1946, the first electronic digital computer was produced at the University of Pennsylvania. Computer biomedical applications began in the late 1950s and have gradually become more pervasive. By the late 1960s, significant progress had been made in the development and availability of computers and of their medical applications. Hospital and office information systems, clinical support systems, automated patient monitoring, and computer-based consulting began.

A 1968 issue of *Bio-Medical Engineering* broached this topic in its *Comment—Can We Avoid Computers?*: “Here almost everything will be new, and only active participation by doctors can ensure that what is devised bears any resemblance to what is really wanted. . . . Whether we like it or not, doctors are going to be confronted by computers in the very near future. Responsibility for whether this confrontation leads to progress or to frustration for both doctors and patients rests largely with the medical profession.”

That challenge still applies. In 1991, the United States’ Institute of Medicine published *The Computer-Based Patient Record*, outlining the essential features of an ideal system and encouraging its widespread adoption (Dick, 1997). While this development has tremendous implications for the quality and cost of medical care, the general adoption of such a system is not occurring as quickly as had been hoped.

Specialization and Regulation Bring Progress and Complexity

Progress in the business of medicine and in improving its quality also have increased its complexity, as reflected in a couple of publications. *Medical and Health care Marketplace Guide* (1997-98), names approximately 5000 entities that sell products and services to health care institutions. The FDA has reportedly registered over 16,000 medical device companies. Government regulations may comprise an appreciable portion of development costs for new devices and for delivering health care. *Health care Standards* (2000) lists over 500 entities that produce standards, laws, and regulations for medical systems and care.

The Health Care Environment as an Ecological System

More recently, NASA has catalogued the vital needs of its self-contained space station environment, necessarily incorporating many of the same environmental requirements of health care institutions. Some exceptions are the considerations for microgravity, extreme accelerations and unusual atmospheres, as well as the implications of those factors for certain other activities.

Hospitals must confront many conflicting needs and paradoxes to achieve a productive, safe, and healthful environment. Patients might be incapacitated by the effects of age, disease, treatments, or disorientation in strange surroundings. Those with compromised immune function must be isolated from those who might harbor virulent disease organisms. Mechanical ventilation support of respiration could predispose patients to pneumonia. Surgical and traumatic wounds and skin punctures could permit the growth and entry of bacteria.

Patients are at risk of infectious diseases that once were thought to be totally under control. Antibiotic-resistant organisms and reservoirs with compromised immune function have created hazardous strains of micro-organisms. They can cause diseases such as tuberculosis, meningitis, pneumonia, and other devastating infections that do not respond readily to commonly used medications. Since the 1970s, some hospitals have been transient reservoirs of deadly organisms which are extremely difficult to treat. Commonplace international travel has served to spread some of these diseases worldwide.

Clinical Engineering Emerges from the Tradition of Bioengineering

Numerous successful medical inventions have arisen from the work of individual scientists, many of whom were physicians. Some fascinating accounts include the development of cardiopulmonary bypass by surgeon Dr. John H. Gibbon, Jr. and his wife Mary Hopkinson Gibbon; cardiac catheterization by Dr. Werner Forssmann, further developed by Drs. Dickinson Richards and Andre Courmand; artificial organ development by Dr. Willem Kolff and colleagues; Dr. Paul Zoll’s external cardiac pacemaker and its subsequent refinement for transvenous internal pacing. With the advances of science and enabling technologies in the late 20th century, engineers were more frequently a part of these developments.

While such inventions have continued to arise, another series of events influenced the role of engineering in medicine. A somewhat exaggerated fear of hospital electrocution arose during the 1960s, prompting hospitals to welcome knowledgeable engineers and technologists to help resolve this perceived institutional problem. In the process, additional benefits of including such personnel in the hospital management and medical care team came to be recognized. Many pioneer clinical engineers began to write their own job descriptions: This is an ongoing process with many opportunities and challenges to meet.

Effective Medical Systems Planning Requires Profound Knowledge

A sound knowledge of basic science and clinical concerns is essential to evaluating, planning, implementing, and maintaining medical diagnostic and therapeutic technologies effectively and safely. For example, despite thorough warnings, many individuals and

institutions have been surprised by the combination of extremely powerful magnetic resonance imaging (MRI) magnets and ferromagnetic objects in close proximity.

Specialized clinical facilities might have particular needs, such as the filtration, temperature and humidity, and high air flow of surgical suites. At times, regulations might be out of synchronization with realistic current needs. Many operating rooms reveal residuals from the time when flammable and explosive anesthetics required special equipment, furnishings, and supplies. The fairly recent adoption of convective patient heaters and other technology helps to protect surgical patients from hypothermia in the cool operating room. At the same room temperature, barrier gowns worn by the surgical team could cause the professionals to be uncomfortably or dangerously warm: A bead of sweat teeming with bacteria could drip into a wound.

Therapeutic oxygen or anesthetic gases could become contaminated or substituted by another gas in error. The stored energy of high-pressure gases could cause barotrauma or could be released explosively to create deadly projectiles. The “fire triangle” of fuel, oxidizer, and ignition source could combine unexpectedly with devastating consequences in health care environments.

The Surgery Suite is a Major Opportunity for Improved Systems

Other facets of the operating room environment need improvement. The typically high noise level of surgical suites is a source of stress and an impediment to clear communication. While lighting is important and generally adequate, further improvement would be welcome. Natural light is not sufficiently used. Most operating-room devices are not designed to fit compactly or to operate well in systems with the commonly found multitude of such equipment.

The disposal of wastes is a pressing environmental concern, especially when medical waste could harbor virulent disease organisms or toxic materials. Vermin and other pathogens can be particularly dangerous within a hospital or clinic.

Safety and Security are Increasingly Vital Issues

Hospital planning and personnel training must consider the special concerns of security and electrical and fire safety. All personnel must be alert to the vulnerability of patients to these hazards. Many such considerations are addressed in *Environmental Health and Safety in Health-Care Facilities* (Bond et al, 1973).

Current controversies include a concern for variations in the incidence of particular treatments or surgeries, and in outcomes. Inefficiencies and errors in medical records and treatment have prompted programs for studying and improving these problems.

Science and Humanity Continue to Battle Superstition and Tradition

John C. Burnham, in *How Superstition Won and Science Lost* (Burnham, 1987), recognizes that ignorance and even well-intentioned social influences can adversely affect the progress of science and medicine. He writes of the ongoing propaganda crusade that began during the nineteenth century: “Like the leaders of superstition in bygone centuries, they (the media) were attempting to assert their authority against the authority . . . of the popularizers of a reductionistic-rationalistic science.”

Ignorance, misinformation, and misconception will continue to be integral to the human condition, despite our best efforts and intentions. Often, superstition, ignorance, and intentional misinformation are used for unsavory purposes. The web site “Junkscience.com” and similar publications serve as helpful contemporary resources on this topic. Junkscience.com—“All the junk that’s fit to debunk”—debunks bad science that is used by personal injury lawyers, social and environmental activists, power-hungry government regulators, politicians, cutthroat businesses, and overly ambitious scientists.

Ongoing Challenges

Previous beneficial innovations have not been quickly adopted, and those now being promoted are likely to face similar obstacles. Among current challenges are those promoted in 1968 by Venzmer (1968), who concluded, “. . . the most urgent task confronting medical science . . . should be the application of the counterbalance to the increasingly unnatural mode of life to which modern man is condemned in this technological age. . . .” Our lifestyle and personal behavior choices are major determinants of health.

The identification of population disease trends can now be supplemented by increasingly detailed knowledge of individual genetic influences. The tremendous benefits to be gained by aggregating individual health data in data warehouses for analysis must be balanced with the need to protect individual privacy.

Mechanisms must be implemented to better link the demands for medical resources with their supply. Feedback mechanisms regarding consequences (or their likelihood) are needed so that individual can make behavior choices.

Conclusion

Regarding the conflicts among social needs, professional ethics, realistic economics, and political regulation, Gordon (1993) concluded his book fittingly: “The intelligent reader will have grasped that the potential of medicine is infinite, the demands on medicine must be unrestrained, but the resources for medicine are limited. Unless a fearless politician strikes a non-political compromise between all three, the history of medicine, like the history of the world in *1066 and All That*, will come to an abrupt end. The history of medicine will not come to an abrupt end, but, like most of our predecessors, we must continually face the challenge of obstacles to our bettering of the human condition.

Enhancing Patient Safety: The Role of Clinical Engineering

American College of Clinical Engineering
Plymouth Meeting, PA

Opportunities for enhancing patient safety exist within the health care delivery system. Individuals and groups throughout the system are actively pursuing these opportunities. The profession of clinical engineering has a unique role to play in enhancing patient safety, particularly with regard to medical technology as it is applied in our health care delivery system.

The American College of Clinical Engineering was established in 1990 to represent and advance the profession of clinical engineering. ACCE has prepared this white paper to share its vision of the role of clinical engineering in enhancing patient safety. We address it to our colleagues within the health care delivery system.

Our message is that clinical engineers, individually and collectively, will continue to work to improve patient safety. Our message is also that ACCE is taking a leadership role in pursuing opportunities for clinical engineering to contribute even more effectively in the area of patient safety. We seek the cooperation and active support of all our clinical, technical, and administrative colleagues in this pursuit.

Patient Safety

Over the past decade there has been steadily increasing concern regarding patient safety. Results from the *Harvard Medical Practice Study* focused attention on the incidence of adverse events in health care delivery (Brennan et al., 1991; Leape et al., 1991). Subsequent studies provided additional quantitative data (Thomas et al., 2000). In a landmark report, "To Err Is Human: Building a Safer Health System," the Institute of Medicine (2000) estimated that medical errors cause 44,000 to 98,000 deaths annually in U.S. hospitals.

One response to the concern for patient safety has been an effort to improve reporting systems for medical errors—including "near misses" in which errors could have caused death or injury but, fortunately, did not. The objectives are to learn from these errors and to find ways to prevent them from recurring. Such efforts have been hampered by controversies regarding mandatory (as opposed to voluntary) reporting, confidentiality of data, and professional liability.

Another response has been to identify existing knowledge and resources that can be applied to the problem. In some cases, the relevant knowledge and resources lie outside the health care delivery system. For example, past improvements in the safety of commercial aviation may serve as a model for health care delivery. In other cases, however, valuable knowledge and resources may be found within the health care delivery system

itself. In this regard, improved cooperation and coordination among health care professionals is considered vital.

Of immediate impact on hospitals and other components of the health care delivery system are new patient safety standards promulgated by the Joint Commission on Accreditation of Healthcare Organizations (2001). The new patient safety standards cut across disciplinary boundaries in an attempt to make safety a fundamental principle of patient care. These standards are linked to long-standing safety-related standards regarding infection control, the environment of care, and other disciplines.

In a follow-up to its earlier report, the Institute of Medicine (2001) has published "Crossing the Quality Chasm: A New Health System for the 21st Century." This report places patient safety within the broader context of quality and calls for a health care delivery system that is safe, effective, patient-centered, timely, efficient, and equitable. Underlying many of the report's specific recommendations is a concern that the health care delivery system is fragmented in ways that produce the opposite of these qualities.

What can be done now to enhance patient safety? First, we can improve our ability to learn from mistakes. Skillful investigation of incidents and responsible sharing of data will help us to identify the root causes of error. Second, we can improve our ability to anticipate mistakes. Cooperation among health care professionals of all disciplines will augment our capacity to probe the weaknesses in the system.

Finally, we can improve the health care delivery system itself. All of us within the health care delivery system can work with other stakeholders to reconfigure the structure of the system, to realign the incentives that guide the system, and to build the resources the system draws on to produce high quality patient care.

Medical Technology and Patient Safety

A defining characteristic of the modern health care delivery system is the ubiquitous use of medical technology. Broadly speaking, medical technology includes not only medical devices, drugs, and biologics, but also the medical and surgical procedures that they enable and the organizational and support systems within which they are used. Diagnosis, monitoring, treatment, and rehabilitation all rely on complex and sophisticated medical technologies.

In today's health care delivery system, the patient is at the center of an intricate network of clinicians, medical devices, and other elements of the system. Every interface

between a human being and a machine contains opportunities for error: Information might not be accurately acquired, recorded, or communicated; necessary actions might not be safely and effectively carried out; and adverse events might occur.

The health care delivery system has been criticized for its "culture of blame" in which culpability for failure has been attributed to the human elements of the system: People make errors; therefore people must change their behavior to reduce errors. However, numerous researchers (e.g., Bogner, 1994; Cook, 1998; Perrow, 1999) have found that human errors are more generally associated with latent causes that are hidden within systems and processes. Current thinking places the responsibility for "human error" squarely on the shoulders of latent (i.e., root) causes that can be prevented only by adjustments to systems and processes.

Simplistic models of adverse events involving medical technology have been based on a dichotomy between "device failure" and "user error." However, more sophisticated taxonomies have been developed that recognize numerous sources of error with the potential for complex interactions among them (ECRI, 1991). To emphasize the multifaceted nature of medical technology application some authors employ the term "use error" rather than "user error" (CDRH, 2000; Hyman, 1995). The critical point is that errors associated with the use of medical technology should not be automatically ascribed to the user. More importantly, efforts to eliminate such errors should not focus on the user in isolation from the system in which he or she works.

In a recent report to Congress (Gardner and Flack, 1999) the U.S. Food and Drug Administration (FDA) stated that under the requirements of the Safe Medical Devices Act medical device manufacturers reported a total of 980 device-related deaths in 1998. In a presentation to the Association for the Advancement of Medical Instrumentation (AAMI, 2000), a representative of the FDA Center for Devices and Radiological Health stated that one-third of the 80,000 incident reports that it receives annually might involve medical equipment "use error." Medical technology is an integral component of the health care delivery system. Efforts to improve patient safety and the quality of health care delivery must take into account the omnipresence of medical technology.

The Clinical Engineering Profession

The American College of Clinical Engineering defines a clinical engineer as "a professional who supports and advances patient care by applying engineering and management skills to health care technology." Clinical engineering became a distinct profession during the 1960s in response to increasing use of medical technology in health care delivery. Since that time, clinical engineering has become a vital component of the health care delivery system, providing leadership in the safe and effective application of medical technology.

Throughout its history, clinical engineering has focused on medical devices as they are used in health care delivery settings: acquiring the appropriate equipment; inspection, maintenance, and repair; regulatory compliance; and related technical issues. Over time, clinical engineering has assumed a leading role in management of medical equipment during its entire life span. As a result, clinical engineers have become deeply involved in quality-improvement and risk-management activities.

Clinical engineers are essential members of multidisciplinary hospital teams investigating incidents in which a medical device might have contributed to injury or death. The clinical engineering perspective can be instrumental in identifying root causes and solutions. An understanding of equipment design principles can produce insights that go beyond the standard behavior of the device in question. An understanding of equipment operation and maintenance can draw attention to likely failure modes and the effect of support systems of device performance. An understanding of systems theory and human-factors engineering can shed light on the interaction between machines and humans.

Clinical engineers have also made contributions to patient safety beyond their own institutions in fields as diverse as anesthesia mishaps (Cooper et al., 1984), radio-frequency interference with medical telemetry (American College of Clinical Engineering, 1998), and remarketing of medical devices (Hatem, 1999). Clinical engineers have advanced the literature of patient safety (Hyman, 1994; Shepherd, 2000) and incident investigation (Bruley, 1994; Dyro, 1998; Shepherd and Brown, 1992). Building on this history, clinical engineers have an important and unique role to play in efforts to improve patient safety.

In the future, individual clinical engineers will continue to act within their own health care facilities to enhance patient safety on a day-to-day basis. Beyond this, the clinical engineering profession will continue to work at all levels within the health care delivery system to improve patient safety and the quality of health care delivery.

The American College of Clinical Engineering

The American College of Clinical Engineering was established in 1990 to represent and advance the profession of clinical engineering, both in the United States and internationally. It has acted both independently and in cooperation with other organizations to achieve its objectives.

For example, ACCE has worked with the U.S. Federal Communications Commission and the American Hospital Association to resolve radio-frequency allocation conflicts that threatened the performance of medical telemetry. Similarly, ACCE has worked with the U.S. Food and Drug Administration and the Association for the Advancement of Medical Instrumentation to establish voluntary standards for the remarketing of medical devices.

Since 1991, ACCE has also conducted numerous Advanced Clinical Engineering Workshops to educate clinical engineers in developing countries on the fundamentals of

technology management. In addition, ACCE has recently assumed management of the clinical engineering certification program established in 1977 by the International Certification Commission on Clinical Engineering and Biomedical Technology.

The ACCE Board of Directors has established an ad hoc committee on patient safety. The committee advises the board of opportunities to advance patient safety in health care delivery. The board has identified several strategies that it will adopt as opportunities occur:

- To seek partnerships at national and international levels to pursue common goals for enhancing patient safety
- To provide formal endorsements of new strategies and methodologies designed to enhance patient safety
- To prepare a directory of publications and other resources for reference and application by health care professionals in enhancing patient safety
- To develop educational programs that improve the skills of health care professionals and their ability to participate in efforts to enhance patient safety
- To review the body of knowledge for clinical engineering certification for inclusion of human factors engineering, root-cause analysis, and other fields of study related to patient safety

The first tenet of the ACCE Code of Ethics calls upon clinical engineers "to strive to prevent a person from being placed at risk of injury due to dangerous or defective devices or procedures." The American College of Clinical Engineering pledges itself to that duty in the far-reaching context of patient safety and high-quality health care delivery.

A Model Clinical Engineering Department

Caroline A. Campbell
ARAMARK/Clarian Health Partners
Indianapolis, IN

Whether creating a clinical engineering department or managing an existing program, the clinical engineer must continuously consider and plan for the resources that are needed in order to perform the clinical equipment management services. Some of the resources that are fundamental to the clinical engineering department's success are staffing, space, test equipment, tools, communications equipment, training, and a computerized maintenance and management system. Because the ability to obtain some or all of these resources will likely be constrained, the clinical engineering manager must think creatively to fill the needs within those constraints. This chapter provides suggested approaches to these situations.

Staffing

The most critical of all resources is adequate and appropriate staffing. Unfortunately, a shortage of clinical engineers and biomedical equipment technicians has created a significant challenge for the clinical engineering managers. Enrollment in biomedical programs is down, and the sophistication of technology is up. These factors have created a high demand for a resource that is in short supply. To attract employees in this climate, the manager must survey the market to verify that the salaries and benefits being offered are competitive (Campbell, 2000). Several journals publish annual salary-survey data that can be useful in establishing appropriate salary structures for each position (Baker, 2000).

The exercise of staffing a clinical engineering department begins with the development of job descriptions, job titles, pay scales, and certification requirements (Pacela and Brush, 1993; Dyro, 1989a, b). Based on the job description, clinical engineering managers must determine the qualifications for the position. Next, the employer must find qualified applicants. The most common way to find qualified applicants is to use "outside" contacts, such as help-wanted advertising in newspapers, journals, web sites, specialized job-placement agencies, schools, colleges, military resources, regional biomedical societies, and nationwide societies. An "inside" search involves limited internal advertising of the position and the use of personal referrals for candidates. Finally, the clinical engineering manager must screen the applicants. Comparison of candidate qualifications to the position description is the obvious first step in this process, but there are other prescreening techniques such as employment testing. Interviewing is the most common way to screen candidates for job positions. Postinterview screening is a final step to help determine the best job-person match. It includes checking references and validating previous employment.

The mix and quantities of employees must be derived from the clinical engineering department's responsibilities. Typical clinical engineering departments employ clinical engineers (CEs), biomedical equipment technicians (BMETs), and administrative support staff. In departments where both CEs and BMETs are employed, the latter typically perform preventive and corrective maintenance, and the former performs pre-purchase evaluation, management of service contracts, risk management, quality control, education and training, and research and development (Glouhova et al., 2000). Administrative support staff is typically employed to answer telephones, bill for services, perform data entry, and maintain files. If the clinical engineering department has responsibilities related to radiation safety, employment of a medical physicist might be warranted. In general, one full-time equivalent is needed in order to support 590 clinical devices or \$2.5 million worth of equipment. Of course, applicability of these metrics depends on the experience level of the staff and the responsibilities of the department (Glouhova et al., 2000).

Training

Because of the tight labor market, the best job candidates will likely not be the perfect candidates. Therefore, the new employee's orientation and training program have become more important than ever. Additionally, provision of training has become an important staff-retention tool (Dyro, 1989).

Training can be negotiated into new equipment purchases to minimize the associated expense. It also can be obtained at cost from original equipment manufacturers or from independent training centers. Technical training seminars are also often offered in con-

junction with professional society meetings. Service manuals must be obtained in order for the training to be beneficial. Teleconferences and Internet-based training provide a cost-effective methodology for training on certain topics.

Space

Space is often a difficult resource to obtain. Successful health care facilities generally allocate the most square footage and the most attractive real estate to patient-care areas. Space may be allocated in one large footprint or scattered throughout the institution. Whatever the case, consciously planning for utilization of the available space will always result in a more efficient environment than will allowing a space plan to develop haphazardly.

Periodic review of the clinical engineering department's short- and long-term objectives is critical to the department's success. All goals need to be reviewed to determine the impact of the environment on the department's ability to fulfill the objectives. Long-term goals might be directly related to space, such as creating the ambience within the department of a world-class service. Other goals can be directly related to provision of a service but can have space implications. For example, a short-term objective of establishing internal support of portable radiology units will require consideration of the width of pathways that will be traveled to get to the point of service. Controls also will be needed in order to minimize unnecessary radiation exposure. These space considerations are integral to fulfilling the objective of establishing internal support of portable radiology units.

Space is not a limitless resource, and hence space planning can include redesign of work processes to better fit the existing space. For example, a shortfall in storage space can be addressed by eliminating hard-copy paper documentation through use of a computerized maintenance-management system (Rice, 1997). A shortage of workspace also might be addressed by pushing certain work out into the patient-care environment. For example, ultrasound scanners frequently can be inspected in patient-care areas after hours. Without this constant balancing of space resources with business practices, the space inevitably will become inadequate and subsequently will impact the efficiency and effectiveness of the department.

If funding permits, an architect should be engaged to help plan and design the clinical engineering space. Usually an architect will be engaged only for a major renovation of space. If an architect is not available, those individuals who are responsible for renovation of space within the institution can provide some guidance for approaching space design. For a successful design, the clinical engineering staff will think about the workflow in terms of its functional needs that are related to space. This will include an exhaustive listing of physical resources, such as gas and water, that are needed for various tasks, as well as quantification of space needed, such as the number of linear feet required for storage of equipment manuals and equipment files. Table 5-1 lists a number of suggested physical resources to be considered in this planning exercise. Using this approach, the space can be designed in a methodical manner to match the needs while fulfilling all applicable codes. For example, if there is only one water source in the department, that is the location where servicing of dialysis machines will take place unless funding is available for additional plumbing. Other equipment requiring a water source, such as humidifiers or lasers, will also be serviced in that location. The workspace surrounding that water source then can be designed around the needs of that same equipment, i.e., parts-storage area and counter space for appropriate test equipment.

Storage space must be designed to accommodate storage of chemicals and test gases, parts, equipment, office supplies, and service documentation. In considering space arrangement, think about what items are always used in one work location, and consider permanent storage of those items in that location. Also consider the items, such as office supplies, that essentially are utilized throughout the workspace. These items might be stored in a central storage depot or interspersed throughout the workspace. Some storage areas may need to be secured. For example, the department's practice may be to restrict access to service documentation. Storage space for staging equipment is necessary. Although not uncommon, the practice of storing pallets of new equipment in a hallway likely violates local fire safety codes. The equipment-staging area ideally will be supplied with ample power and will contain adjustable shelving.

Table 5-1 Infrastructure resource considerations

Equipment work area	Resources
Anesthesia/respiratory therapy	<ul style="list-style-type: none"> ● Phone and data outlet ● Ample power outlets ● Gas outlets (nitrous oxide, oxygen, air, vacuum) ● Large sink and cup sinks ● Parts storage
Dialysis	<ul style="list-style-type: none"> ● Phone and data outlet ● GFI outlets ● Compressed air ● Recessed water spigots with raised drains ● Parts storage ● Sealed-membrane floor with floor drain
Radiology	<ul style="list-style-type: none"> ● Phone and data outlet ● 50A, 220V single-phase power ● Portable lead shield, lead-lined doors ● 10-ft. ceiling ● Wide-access door (48 in.) ● Incandescent light on dimmer switch ● Beam and hoist with 1-ton load capacity ● Deep-utility sink ● "Room in Use" light ● Power for wall-mounted view box
General workbench	<ul style="list-style-type: none"> ● Ample power outlets ● Static mat ● Electrostatic-free outlet ● Durable countertop ● Lockable drawers ● Manometer mount ● Vacuum ● Air ● Phone and data outlet

Since the core work of the clinical engineering department takes place at the workbench, this area deserves the most investment of attention and resources. The workbench design optimally will incorporate sufficient countertop space, adequate storage space for test equipment and tools, and appropriate resources such as vacuum, grounding mats, and access to sufficient quantities of electrical outlets. To make efficient use of the workbench space, shared resources can be mobilized by mounting on a cart. For example, a mobile solder station can be conveniently brought to the workbench, where a device is already disassembled, instead of bringing printed circuit boards to the stationary solder station.

The needs of a reception area are distinctly different from the equipment service area. The reception area will be used to receive the customers and business partners of the clinical engineering department. Comfortable seating in good repair is needed to accommodate these guests. Because the prestige of the department is partly dependent on the impressions of these individuals, the reception area must be a more traditional office space that is shielded from the noise of drill presses and equipment alarms. The design of the reception area typically supports the administrative work processes of the department and hence typically includes such things as computers, printers, fax machines, copiers, filing cabinets, and desk furniture. Much of the office equipment can be hidden in well-designed closets that are opened as needed for access. In this manner, the clutter of the workspace is minimized while accommodating convenient access.

Critical staffing shortages are facing many clinical engineering departments, and the impact of the work environment on recruitment and retention therefore must be considered. Although a functional space design is necessary for a successful department, creation of the desired ambience must be woven into that functional design. Lighting is a critical factor in creating a desirable ambience. If funding is available, artwork can be very effective in humanizing a technical environment. Mounting of personalized name plates on the workbenches of employees is an example of an inexpensive approach to creating an environment of mutual respect. Personalization of workspace is also a work-satisfaction issue that can be accommodated easily. Provision of small bulletin boards for the posting of family pictures allows for this personalization while avoiding the taping and tacking of things such as pictures and calendars to the walls. No matter how much effort and money is invested in creating the ambience, a dirty environment will always be seen as a dirty environment. Therefore, making arrangements to clean equipment before entering the department and for maintaining order within the department is critical.

Computerized Maintenance and Management System

The foundation of the successful clinical engineering program is the computerized maintenance and management system (CMMS). This database will house the information that the clinical engineering staff will use to make informed decisions and recommendations relating to equipment management. Careful selection of a computerized maintenance and management system will permit access to this information using a variety of queries and the ability to format the information in a useful manner. The CMMS also has evolved into an important process tool for organizing the work of the department.

Although some clinical engineering systems develop their own CMMS, there is a variety of products available on the market. Some of these products are designed specifically for clinical engineering and interface with common test equipment; others are more

generic service-industry packages that can be adapted to suit the purposes of clinical engineering. At a minimum, the selected CMMS should permit keeping an equipment inventory with a variety of information including a unique numeric identifier, manufacturer, model number, and serial number, and it should have the capability to generate work orders on a scheduled basis and on demand. Other attractive features include the capability to track a parts inventory and parts utilization, financial tracking capability, and payroll functions. Often these various features are arranged in modules that interact with one another. A high degree of integration between modules is a desirable feature of a CMMS. For example, some systems contain a module for definition of device specific preventive maintenance procedures that can be married to specific devices in the inventory module. When a scheduled preventive maintenance work order for that specific device is generated, the appropriate preventive maintenance procedure appears in the work order module screen.

Access to the CMMS by the clinical engineering staff is desirable wherever work with equipment is performed. Therefore, transportability of the CMMS into the clinical care environment is also a desirable feature. This can be accomplished through connection to the hospital's backbone—wireless communications—or through upload/download of the database (or some portion) onto portable devices.

Test Equipment and Tools

The contents of the test equipment inventory will depend upon the kinds of clinical equipment supported by the clinical engineering department. However, every test equipment inventory will contain certain multipurpose items that will be used to support a variety of clinical equipment. At a minimum, the test equipment inventory will include a digital multimeter, oscilloscope, rheostat, electrical safety analyzer, and patient simulator with ECG and pressure capabilities. Large departments will find it necessary to acquire common test equipment such as multimeters and electrical safety analyzers for most, if not all, BMETs.

Many test devices are specific to clinical devices, e.g., electrosurgical unit tester, defibrillator output tester, and hence a thorough review of the clinical equipment inventory is required in order to determine the appropriate test-equipment inventory. Additionally, as clinical equipment is added to the support responsibilities of the department, a review of the requisite test equipment to fulfill those responsibilities is needed. Table 5-2 lists common test equipment that is needed to support various medical devices.

A set of hand tools also will be necessary to fulfill equipment-support responsibilities. Sharing of tools is not recommended as individuals tend to be particular about the order and condition of the tools that they use. Hence, the completeness and condition of the tool set tends to be a work satisfaction issue. The wise manager will budget annually for replacement of worn and lost tools. Specialized tools that are not frequently needed are more appropriate for sharing.

Communications Equipment

Communications is an integral part of every service industry (Maddock and Hertzler, 1999). The clinical engineering manager will be wise to make a list of the various types of communications that will occur, and then will incorporate appropriate communications equipment to facilitate that exchange. For example, telephone access at the workbench will facilitate conversation with a manufacturer's technical support group with the device under repair within easy reach. A wireless telephone will facilitate this same conversation for devices that cannot be removed from the clinical environment. Communications

Table 5-2 Suggested test equipment

	● Oscilloscope
General	<ul style="list-style-type: none"> ● Function generator ● Electrical safety analyzers ● Multimeters ● Capacitance meter ● Transistor tester ● Pressure gauges ● Tachometer ● Rheostat ● DC power supply ● Patient simulator ● Frequency counter ● Flowmeter ● Calibrated weights
Specialty	<ul style="list-style-type: none"> ● Ventilator tester ● Respirometer ● Gas analyzers ● Electrosurgical unit tester ● Defibrillator tester ● Spectrum analyzer and antennas ● Oxygen monitor ● Laser sensor and power meter ● Audiometric analyzer ● X-ray phantoms ● Radiation detector ● Collimator test tool ● Ion chambers ● Resolution test tool

devices that will be considered include telephones, fax machines, and computers with Internet access. In this electronic age, the clinical engineering manager also must remember that sharing hard-copy documents continues to play an integral role in communications and therefore will remember to provide bulletin boards and mailboxes.

Communications equipment also permits locating a particular staff member when there is an urgent need requiring that staff member's attention. This can be accomplished utilizing a pager, a two-way radio, or an intercom system. Each of these approaches has limitations including coverage area and contribution of noise (i.e., sound and/or electromagnetic energy) to the clinical environment.

Conclusion

Each clinical engineering department will require some customization based on the services that it will provide and the resources that will be provided to it. However, every clinical engineering manager will need to consider and incorporate staffing, space, test equipment, tools, communications equipment, training, and a computerized maintenance-management system into the department's plan. This chapter has provided a template for considering the resource needs of the clinical engineering department; however, the clinical engineering manager is encouraged to approach each of this with creativity. Other ideas for utilizing resources in the development and implementation of a clinical engineering department often can be obtained from the work of other clinical engineers (Dyro, 1993; Soller, 2000; Hughes, 1995; Gupte, 1994).

6

The State University of New York, Health Science Center at Brooklyn—widely known as Downstate Medical Center—is located in the heart of urban Brooklyn, New York. Downstate traces its roots back to 1860, when the nation's first hospital-based medical school, Long Island College Hospital (Collegiate Division), was founded in Brooklyn under a New York State-granted charter. For the first time, bedside teaching was included in the curriculum, forever changing the course of medical instruction. The school was renamed the Long Island College of Medicine in 1930, and in 1950 it merged with the State University of New York system and was called the College of Medicine at New York City. In 1985, the institution was renamed the State University of New York Health Science Center at Brooklyn (SUNY HSCB) (Guide to the Archives, 1966).

Today, Downstate is a multifaceted institution providing patient care, education, research, and community services. It serves as a regional resource for Brooklyn, Staten Island, and the surrounding vicinity. It is Brooklyn's premier center for the education of health professionals and one of the leading such centers in the New York metropolitan area.

Downstate is one of New York's leading centers of biomedical research. In 1998, it received worldwide recognition when Dr. Robert Furchgott, distinguished Professor Emeritus, was awarded the Nobel Prize in Medicine for his discovery of the role that nitric oxide plays in the contraction and dilation of blood vessels. Downstate is also well known for the development of magnetic resonance imaging (MRI) by Dr. Raymond Damadian (who produced the first human images in the world using MRI), as well as for the establishment of the nation's first federally funded dialysis program by Dr. Eli Friedman.

Downstate Medical Center consists of the following:

- College of Medicine
- School of Graduate Studies
- College of Nursing
- College of Health Related Professions
- University Hospital of Brooklyn
- Research Foundation

Clinical Engineering in an Academic Medical Center

Ira Soller

Director, Scientific and Medical Instrumentation
SUNY Health Science Center at Brooklyn
Brooklyn, NY

University Hospital of Brooklyn (UHB) is the teaching hospital of Downstate Medical Center. This comprehensive 376-bed facility with several primary-care satellite clinics provides a full range of services from primary and preventive services to tertiary care.

Scientific and Medical Instrumentation Center (SMIC)

History

The Biomedical/Clinical Engineering Department serving Downstate is one of the oldest clinical engineering programs in the nation. SMIC was established in 1963, under the leadership of Dr. Seymour Ben-Zvi (Ben-Zvi and Gottlieb, 1980), several years before Dr. Caceres coined the term "clinical engineering." SMIC's current Director, Ira Soller (Figure 6-1), appointed in 1993, has been on staff since 1977, previously serving as assistant, associate, and acting director.

SMIC has historically supported activities that include the design and development of equipment and devices (usually associated with biomedical engineering research, as well as involvement with medical equipment applied to patients in a clinical setting, a clinical engineering function). Having such versatility, SMIC is capable of providing services in support of all of the goals expressed in Downstate's mission statement, (i.e., patient care, education, research, and community service).

From its inception, SMIC was acknowledged to be one of the leading clinical engineering departments in the country. On April 22, 1970 the W.K. Kellogg Foundation awarded SMIC a \$129,216, three-year grant to develop and conduct the nation's first experimental in-house preventive maintenance (PM) program for hospital medical equipment, thus addressing the need to improve equipment maintenance throughout the industry. This PM program proved so successful that it served as a prototype for hospitals throughout the country. Interestingly, this award was made prior to Ralph Nader's article

Figure 6-1 Ira Soller, MSEE, PE, SMIC, Director of Biomedical Engineering.

in the *Ladies Home Journal* (March 1971) that raised national consciousness about accidents that could occur in hospitals as a result of poorly designed or faulty medical equipment, and recommended that hospitals hire engineers to eliminate these dangers. This helped to spur the growth of the clinical engineering profession (Curran et al., 1974; Soller, 1999).

Throughout the years to satisfy the needs of the dynamic Downstate environment, SMIC expanded its equipment-support capabilities to provide a diverse range of services to researchers and clinicians. Centralization of hospital equipment management and instrumentation technical services under one department made sense both economically and logistically. It has been demonstrated repeatedly that such services could be provided effectively and in a more timely fashion by in-house staff.

Creative Exposure

Life within a large academic institution, and a teaching hospital in particular, presents many challenges. One must be able to change focus and to prioritize as situations and emergencies dictate. This dynamic environment requires the delegation of tasks and necessitates supervisory clinical engineering staff to have the ability to make independent decisions.

Talented technical personnel are drawn to SMIC because of the Downstate environment, as it offers them exposure to the latest technologies and provides greater opportunity for professional growth than that offered in a nonteaching hospital setting. The depth and breadth of knowledge necessary to meet Downstate's challenges, however, requires SMIC clinical engineers to have expertise in a multitude of disciplines including the basic sciences (e.g., chemistry, physics, and optics), physiology, engineering (e.g., thermodynamics, electronics, and mechanics), and information technology, in addition to having knowledge of regulatory agency requirements, health care codes, and medical equipment standards.

Unique Involvement

Downstate's diverse academic medical center environment has allowed SMIC to have many unique involvements throughout the years. SMIC folklore includes fond tales of Dr. Damadian "scrounging" some parts from SMIC to assist in his development of an MRI machine at Downstate. Over the years, other researchers in addition to Dr. Furchgott have used SMIC services. These include Dr. Henri Begleiter, who studied the genetics of alcoholism, Dr. Mimi Halpern, who studied the sensory system in vertebrates, Dr. Alan Gintzler, who worked on pain perception and addiction (Baron et al., 1983), and Dr. Madu Rao, who developed direct calorimetry in preterm infants (Rao et al., 1995). Likewise, Dr. Randall Barbour requested SMIC's assistance in the development of a near infrared, clinical imaging system that has the potential of becoming as important as MRI (Barbour et al., 2000). As a result of these and other activities, several SMIC staff members have been acknowledged in clinicians' and researchers' technical papers and presentations and have received numerous awards.

SMIC Logo

SMIC's support services to the hospital, academic, and research communities were captured in SMIC's logo, designed by Ms. Tobey Soller, graphic designer, in 1993. The logo consists of a white circle (representing a medical or scientific instrument display screen) containing the green letters SMIC (representing the vitality of an ECG trace), all contained within a blue square (representing Downstate Medical Center and

Figure 6-2 Medical Equipment Management. Associate Directors, Leonard Klebanov and John Czap, are key players in SMIC's efforts to assure that safe, efficacious, medical equipment is acquired, properly tested, and cost-effectively maintained at UHB. Together they have more than 50 years of experience working in the clinical engineering field.

University Hospital of Brooklyn). Taken as a whole, the logo represents a dynamic biomedical/clinical engineering department providing diverse services to the Downstate community.

SMIC Program Services

A summary list of SMIC's biomedical/clinical engineering program services in support of Downstate's mission follows (Wilkow and Soller, 1995). These services are later discussed in detail.

Patient Care

- Acceptance testing (initial checkout, incoming inspection, incoming testing) of new equipment for safety, proper operation, and adherence to manufacturers technical specifications
- Bid evaluation for the purchase of medical equipment and related services
- Centralized patient care instrumentation history files
- Centralized instrumentation technical manuals library
- Clinical engineering consultation
- Clinical engineering participation on Hospital and Health Science Center committees
- Clinical engineering staff and departmental development activities
- Computerized medical equipment inventory
- Coordination of outside medical equipment repair/maintenance services
- Dedicated clinical engineering support to the cardiothoracic open-heart program
- Emergency clinical engineering support, all patient-care areas and operating rooms
- Expert witness testimony
- Hazard and recall alert notification
- Medical equipment asset management
- Medical equipment defect resolution
- Medical equipment evaluation library
- Medical equipment installation supervision and coordination.
- Medical equipment modification
- Medical equipment planning for clinical areas and new programs
- Medical equipment pre-purchase evaluation
- Medical equipment preventive maintenance (PM, scheduled maintenance)
- Medical equipment relocation (as patient areas are refurbished)
- Medical equipment repairs (unscheduled maintenance)
- Medical equipment upgrades
- Medical equipment user in-service education
- No fault found/user error/cannot locate, tracking
- On-call/recall support for critical-care areas and the operating rooms
- Oversight and evaluation of equipment-service contracts
- Patient-related equipment-incident investigation
- Preventive maintenance test procedure generation and update
- Purchase requisition review
- Quality assurance and risk management
- Regulatory agency inspection support (American Association of Blood Banks (AABB), College of American Pathologists (CAP), Department of Health (DOH), Food and Drug Administration (FDA), Joint Commission on Accreditation of Healthcare Organizations (JCAHO)

- Report generation to hospital administration (including clinical capital equipment purchase tracking), the safety committee, and other hospital committees
- Representation of the hospital on the University Healthcare Consortium (UHC) Clinical Engineering Council, and at Greater New York Hospital Association (GNYHA) meetings
- Representation of the hospital in the New York City Metropolitan Area Clinical Engineering Directors Group
- Request-for-quotation (RFQ) generation
- Technology assessment
- Testing of rental, loaner, demonstration, patient-owned, and physician-owned equipment for hospital use
- Vendor and manufacturer interface

Research

- Design, development and construction of specialized instrumentation and devices including electronic, electromechanical and mechanical
- Engineering consultation
- Institutional Review Board (IRB) approval assistance
- Laboratory measurement assistance
- Patent and grant-writing assistance
- Scientific equipment repairs, modification, and upgrade

Educational and Community Involvement

- BMET internship program
- Electrical Engineering Technology Advisory Committee (SUNY Farmingdale)
- Lectures (medical equipment-specific and safety issues)
- Volunteer training

SMIC Support for Patient Care

SMIC's primary focus, to which almost all of its resources are allocated on a day-in day-out basis, is in support of University Hospital of Brooklyn (UHB) and its patient population.

Environment of Patient Care

Providing engineering expertise to ensure that the environment of patient care is safe for both patient and clinician is at the heart of SMIC's clinical engineering program in support of UHB. Medical equipment used on or for patient care comprises a large part of this environment. It must be safe, efficacious (i.e., performing the function for which it was intended), and cost-effective. SMIC's clinical engineers provide technical-support services to ensure this, thus reducing risk to the institution, its patients, and staff. Their diverse body of knowledge and experience enables them to have a unique understanding of the ways that technology and patient care interact within the clinical setting (ECRI, 1989) and is vital when medical equipment is integrated into the environment of patient care. They are able to interface medical systems to the patient and to other medical systems including those that are used for patient data collection (Shaffer, 1997). Their knowledge has proven invaluable to UHB.

Medical Equipment Management

Scope

Medical equipment management (David and Judd, 1993), a cornerstone of SMIC's clinical engineering program, concerns not only equipment maintenance (PM and repair) but also encompasses services that cover the entire life cycle of the patient-care and patient-related medical instrumentation used at UHB. SMIC services start with the planning stages prior to equipment purchase and, as required by the equipment-tracking requirements of the Safe Medical Devices Act, conclude with the formalities of retirement and disposal of older units from service—after their usefulness (i.e., functional or technological) is over (Shepherd, 1996).

SMIC's medical equipment management program is compliant with JCAHO guidelines and regulatory requirements of the Department of Health (DOH), the College of American Pathologists (CAP), and the American Association of Blood Banks (AABB).

The program is involved with equipment acquisition including equipment assessment (pre-purchase evaluation), equipment specification, purchase requisition review, RFQ generation, bid analysis, and vendor selection (See Figure 6-2). It includes installation planning, acceptance testing, defect resolution, user in-service education, selection of service provider, product recall and alerts, incident investigation, and equipment replacement cost analysis and disposal. It strives to save money by reducing equipment downtime and resultant lost patient revenue, and it minimizes the need to pay for equipment rentals. It also allows equipment replacement decisions to be made based not only on equipment capabilities but on past equipment failures and expenses as well. Standardization of equipment and consumables is also encouraged (Cohen, 1994).

Device Responsibility

SMIC is responsible for approximately 10,000 active medical devices. The number changes daily as new equipment is acquired and older equipment is retired from service. The equipment runs the gamut from simple electronic thermometers to sophisticated ultrasound imaging systems, located throughout the institution. To bring order to this vast array of medical equipment and to simplify the gathering and distribution of data relating to these medical devices, SMIC follows the medical device classification nomenclature found in *Health Devices Sourcebook* and *Medical Device Register*. At present, 500 dif-

Figure 6-3 Administrative Support. SMIC's Administrator, Marcia Wilkow, tracks clinical capital equipment purchases and clinical engineering's purchases. She and SMIC secretary, Emma Johnson, are reviewing purchase requisition information.

ferent equipment nomenclatures are used to describe this equipment, the large number suggesting the breadth of knowledge that SMIC staff must have.

SMIC's mandate does not include X-ray or ionizing radiation devices, which are managed by the Radiation Physics Department, nor devices such as stretchers, hospital beds, and wheelchairs, which are maintained by the Facilities Management and Development Department.

Procurement of Medical Devices

UHB acquires medical equipment for a multitude of reasons. These range from the need to replace obsolete equipment to the acquisition of new technology and specialized equipment for new clinical programs, allowing enhanced services to be provided to the community.

SMIC plays a role in the acquisition process by providing input to hospital administration and the Clinical Capital Equipment Acquisitions Committee. Through a purchase requisition review process SMIC ensures that everything required (e.g., peripheral items and supplies) is ordered and that all items are compatible with each other and with existing equipment. This process also ensures that the physical plant is made ready to accept the new equipment, thus expediting equipment installation and use (Soller and Klebanov, 1992). SMIC's Administrator maintains a Clinical Capital Equipment Tracking Spreadsheet Report of all clinical capital equipment purchases, and SMIC works closely with Purchasing and Expenditures Processing to ensure that medical instrumentation is neither ordered unless the purchase requisition has been reviewed nor purchased until the device has successfully passed SMIC acceptance testing. (See Figure 6-3.)

SMIC is also involved in technology management issues relating to proposed new acquisitions. For example, SMIC served on an MRI Acquisitions Committee, visited the vendors manufacturing site, and generated reports for UHB's medical director concerning the acquisition of an Open-MRI device (AAMI, 1997).

New and Renovated Area Planning

SMIC's involvement extends to technical issues relating to medical equipment planning for renovated and new areas within the Hospital. SMIC provides assistance to the clinical staff in determining the location of the medical devices; guidance in connecting new systems to existing systems; and oversight of vendor or manufacturer equipment installation including adherence to contractual requirements (e.g., timeliness of installation). During renovation of existing areas, SMIC assists in safeguarding existing equipment to prevent damage.

Turnkey Installations

SMIC is called upon during request for quote (RFQ) generation, bid evaluation, purchase requisition generation, and acceptance testing for such systems. Although RFQ documents may include equipment and environmental specifications and legal requirements that address issues of noncompliance and penalties, it has been SMIC's experience that large turnkey systems require extensive vendor or clinical engineering interaction and problem solving as installation progresses as documentation for all contingencies is not always possible. Also, several layers of acceptance testing may be required; e.g., bench

Figure 6-4 Acceptance Testing. Senior biomedical engineers, George Martin and Semyon Ullis, verifying correct operation of a newly purchased microscope to ensure that it is safe for use and that it performs according to manufacturer specifications, and rectifying any defects prior to its being released for clinical use. Payment is not authorized until the unit has successfully passed the acceptance-testing process.

testing of components prior to, as well as after, inclusion in subsystems followed by final global acceptance testing.

Acceptance Testing of Medical Devices

SMIC staff perform acceptance testing, also known as “initial checkout” or “incoming inspection,” prior to new devices being placed into service. SMIC also performs an appropriate level of acceptance testing for physician-owned, rental, loaner, donated, or demonstration instrumentation prior to an item being placed into service.

Acceptance testing tends to be more in-depth than PM testing and entails more than just electrical safety testing, e.g., leakage current and grounding resistance. (See Figure 6-4.) This process ensures that all equipment to be used on or for patients functions properly and is safe, both for the clinical user and the patient. Acceptance testing uncovers equipment defects including those not readily apparent, allowing for correction prior to the equipment being placed into service, thus reducing liability to the institution. Sometimes design errors are uncovered as well. Acceptance testing also provides a practical training ground for SMIC’s staff, thus allowing people to become familiar with new equipment prior to the occurrence of an emergency clinical situation or patient incident involving this equipment that would require their assistance (Polaniecki, 1989).

Equipment Maintenance and Repair

Proper equipment maintenance and repair, a core element of equipment management, is paramount for an institution to be able to provide high-quality medical care. (See Figure 6-5.) A clinical engineering director must be flexible and fully aware of the skills of the clinical engineering staff and the budgetary constraints of the institution in order to select the proper cost-effective mix of services, the intent always being to provide quality service and to reduce overall costs (Gordon, 1995).

SMIC avails itself of several methods of providing equipment service. Although SMIC provides in-house maintenance and repair for a full range of sophisticated, state-of-the-art medical equipment, which includes anesthesia machines, ventilators, and dialysis units, outside OEM vendor repair and service support is sought out for specialized equipment, as required to supplement in-house capabilities; i.e., equipment that must be con-

Figure 6-5 Preventive Maintenance. Senior biomedical engineer, Lenworth Howe, performing preventive maintenance on a cell saver. Preventive maintenance can be more involved than just performance of a functional and safety test. Problems uncovered must be rectified, and some instrumentation requires that components be replaced due to wear or number of hours of use.

tinuously operational in order to minimize revenue loss to the institution and for which there is little or no back-up equipment. (See Figure 6-6.) SMIC monitors the outside services to ensure work quality, receipt of appropriate documentation for entry into the equipment history files and computerized system, and correct charges (Cohen, 1994).

Providing service to UHB’s off-campus facilities (i.e., three clinics, a dialysis center, and a school based clinic) presents challenges that require careful coordination, particularly in transporting equipment and staff between locations, exchanging equipment, and assisting in regulatory inspections.

Emergency Support

SMIC engineers provide on-site troubleshooting during normal working hours to all patient-care units, the operating rooms, and offsite facilities (See Figure 6-7). After hours, on weekends, and on holidays, SMIC provides on-call and recall support to the operating room and critical care areas. SMIC engineers also assist during physical plant emergencies (e.g., water leaks) to safeguard medical equipment.

Cardiothoracic Surgery

One unique SMIC service is the support of UHB’s Open Heart Cardiothoracic Surgical Team. A SMIC clinical engineer is dedicated to the team and is present during each case. (See Figure 6-8.) SMIC’s engineer assists in equipment setup prior to the operation, equipment troubleshooting during the surgical procedure, patient transport to an appropriate intensive care unit, and bedside physiological monitor connections (Soller, 2000).

Although SMIC clinical engineers assist in the operating room, they do not independently operate the medical equipment or select levels of treatment, e.g., time balloon pump inflation and deflation, prepare medications, heparinize saline solutions, or give fluids to or take fluids from patients by way of, for example, a cell saver or rapid infusion system. Trained clinical specialists, perfusionists, and licensed technicians perform these tasks. However, clinical engineers do provide instrumentation troubleshooting expertise during these procedures.

Risk Management

SMIC’s clinical engineering program provides an important oversight function whose purpose is to reduce risk of injury to patients and staff as well as liability to UHB. UHB’s Quality Assurance and Risk Management Departments routinely look to SMIC for assistance with regulatory issues, agency surveys (e.g., JCAHO, FDA, DOH, AABB, and CAP), patient- and equipment-incident investigation, and hazard and recall alerts. (See Figures 6-9 and 6-10.) SMIC staff also have been called upon to give testimony as expert witnesses. In addition, user error, equipment abuse, and no-fault-found occurrences are tracked to assist Risk Management in determining whether additional clinical staff in-service training is required.

Figure 6-6 Repair. Senior biomedical engineers, Simon Gerecht and Michael Salts, utilize their extensive electronic troubleshooting skills during repair of an infant warmer to ensure that the thermostat controls are functioning properly.

Clients/Committees/Meetings

SMIC's clinical engineers interface daily with staff from various departments and entities within our health care institution. All of them are considered to be clinical engineering clients and are treated as such. A partial list includes facilities engineering and planning, hospital administration, cardiothoracic surgery, central sterile, expenditures, contracts, risk management, OPD administration, clinics, clinical labs, ambulatory surgery, pharmacy, surgery, anesthesiology, ophthalmology, orthopedics, offsite satellite clinics, clinical areas, nursing units, personnel department, purchasing, and cardiology. Interaction between researchers and educators also occurs.

Such open interaction is essential for a successful clinical engineering program. SMIC maintains that clinical engineering departments must continuously prove themselves, especially as an institution's staff changes. New employees, both administrative and clinical, might be unfamiliar with the benefits of in-house clinical engineering services. Continuous advertising promotion, such as by means of flyers and bulletin boards and attendance at meetings, is required in order to educate them to clinical engineering's vital role within the institution. Report generation serves a similar public relations function.

Committee participation is particularly important. It enables clinical engineering to provide timely feedback to the clinical user on equipment-related issues and questions. This maintains and improves channels of communication between SMIC and its clients. It also allows trends to be spotted such as equipment that is inoperable but not yet reported to clinical engineering.

SMIC staff coordinated the Y2K process at the Hospital and Health Science Center, obviating the need for outside consultants and thus considerably reducing hospital expenditures. SMIC's involvement on various Y2K committees within the Greater NY Hospital Association and SUNY Central in Albany, NY, benefited the institution by raising conscience levels, which resulted in sound cost-effective business decisions for Downstate and University Hospital (Soller, 1999).

SMIC Support for Research

Research support includes consultation assistance in selection of experimental equipment, laboratory setup, measurement technique, grant writing, patent applications, and IRB approval. This support also entails the design, prototype development, and final construction of special-purpose devices that are not readily available commercially or that can be more cost-effectively built in-house.

Involvement in research and educational activities is beneficial. These challenging opportunities help to keep SMIC staff technically competent and involved at the forefront of technology. Such activity also brings prestige to the department, enhancing its professionalism and reputation. To be effective, a team with diverse expertise in electronics, mechanics, and physiology is often required.

SMIC Support for Education and Community Involvement

Education

SMIC supports the Continuing Education Department by coordinating in-service training for the clinical staff on specific medical instrumentation and provides tutorials on safety issues within the clinical environment. SMIC also presented a Post-Baccalaureate Medical Monitoring Course for Downstate's College of Health Related Professions Cardiovascular Perfusionist Program.

SMIC's involvement with SUNY Farmingdale's Electrical Engineering Technology Department led to the establishment of a Biomedical Engineering Technology Internship program. Recently, SMIC was requested by the City University of New York, New York City Technical College to advise in establishing a biomedical engineering technology program.

SMIC has also made clinical engineering presentations to outside institutions; e.g., Brooklyn Museum's *Big Adventure Program* for children; Columbia University's Bioengineering Conference; and Touro College's Levine School of Health Sciences. (See Figure 6-11.)

Community Involvement

Community involvement, provided through on-the-job training programs, has included UHB's volunteer program and the New York Association for New Americans (NYANA) internship program for newly arrived immigrants. When properly supervised, SMIC has found intern and volunteer interaction to be beneficial. For example, qualified volunteers were utilized when the department was faced with the task of multiple device equipment acceptance testing for 300 infusion pumps.

Staff

Overview

SMIC's Director, Ira Soller, MSEE, PE, a recipient of the SUNY Chancellor's Award for Excellence in Professional Service (SUNY Focus, 1996), plays an active role in the clinical engineering community. He presented at AAMI Expositions on clinical engineering legal testimony (Soller, 2001), the impact of health care changes on clinical engineering (Soller, 1996; Soller, 1999), clinical engineering department restructuring (Soller, 1997), and the philosophy of clinical engineering (Soller, 2001). He also contributed to the University Health care Consortium *Compendium of Cost Saving Projects* (UHC, 1995; UHC, 1997) and was an invited panel member at their benchmarking roundtable discussion (Soller, 1995). As a member of the Greater New York Hospital Association (GNYHA) Y2K Workgroup, he was active in defining appropriate policy. He is Coordinator of the

Figure 6-7 Emergency Support. SMIC plays a key role in providing emergency support to troubleshoot and answer questions relating to equipment operation and capability. Associate Director, Leonard Klebanov, is shown testing to ensure that a balloon pump is functioning properly. This device provides support to critically ill patients by reducing their heart's workload until it strengthens. Balloon-inflation and -deflation timing and mode of triggering ensure optimal patient assistance.

New York City Metropolitan Area Clinical Engineering Directors Group (see Chapter 132) and a representative to AAMI's Biomedical Organizations Committee (Soller, 1999d). Mr. Soller serves on SUNY Farmingdale's Electrical Engineering Technology Advisory Committee and served on its Biomedical Engineering Technology Advisory Committee assisting in establishing an internship program at SMIC. For several years he taught a post-baccalaureate medical monitoring course for Downstate's College of Health Related Profession's Cardiovascular Perfusionist Program and served on its Program and Curriculum Review Board. In 1999, Mr. Soller received an American College of Clinical Engineering Advocacy Award for authoring his article on clinical engineering that was published in the *Wiley Encyclopedia of Electrical and Electronics Engineering* (Soller, 1999). He has been called upon to serve as expert witness of patient incidents and is listed in Strathmore's *Who's Who* (1998-99).

Among SMIC's clerical and administrative support staff of 20 are the following individuals:

John Czap, associate director, has participated in seminars for OSHA and FEMA and has been involved with the New York City Mayor's Office of Emergency Management Special Needs Assessment Program. He is a member of the NYC Emergency Medical Services Council regional faculty. Mr. Czap is SMIC's lead person for patient incident investigations, regulatory agency inspections, and response to environmental emergencies that could affect UHB's medical equipment. His expertise in RF communications is invaluable in matters concerning electromagnetic interference (EMI).

Leonard Klebanov, associate director, is routinely involved in medical instrumentation issues including purchase requisition review for new sophisticated electronic equipment and systems, their acceptance testing, and coordination of installation activities. He oversees the replacement of the hospital-wide physiological monitoring equipment. Mr. Klebanov also supervises SMIC's on-call/recall team, including the support that it provides to cardiothoracic surgery, and serves on the IRB committee. Staff both within and outside SMIC rely on his expertise on technical issues requiring cost-effective solutions.

Administrator Marcia Wilkow adds financial and administrative expertise which is vital to department functioning. Her desk serves as command center, especially during times of crisis. Ms. Wilkow's responsibilities include personnel issues, management of data

Figure 6-8 Cardiothoracic Surgery Support. SMIC's specially trained engineer is available in the operating room to check the physiological monitoring equipment prior to patient connection as well as to troubleshoot equipment problems should any develop. Biomedical engineer, Boris Shamrakov, is shown checking a patient bedside monitoring setup in the Cardiothoracic Surgical Intensive Care Unit to ensure its functionality and rapid connection upon patient arrival following surgery.

Figure 6-9 Incident Investigation. Equipment-related incident investigation is conducted by SMIC whenever a medical device might have caused injury to a patient or clinician. SMIC staff also may anticipate and resolve equipment problems before they result in an incident. Associate Director, John Czap, is shown with an examination lamp bracket that did not meet original equipment-manufacturer (OEM) specifications, which could result in the lamp being easily dislodged and falling. The bracket manufacturer and supplier worked with SMIC to resolve the issue and supplied newly designed brackets.

Figure 6-10 Regulatory Inspection. SMIC staff provides technical assistance during regulatory and accrediting inspections. Here, Lab Supervisor, Sophia Zikherman, discusses an upcoming Department of Health inspection with senior biomedical engineer, Stanley Wei, and biomedical engineers, Yefim Brayman and Michel Chery.

collection and recordkeeping activities relating to SMIC's equipment management program, purchase order tracking, new capital equipment purchase tracking, documentation of SMIC policies and procedures, annual budget preparation, monthly financial analysis, report generation, and interaction with anyone who seeks SMIC services.

Lab supervisors, Luis Cornejo and Sophia Zikherman, contribute important technical expertise. Mr. Cornejo, an expert on sophisticated electromechanical equipment (e.g.,

ventilators, dialysis equipment, and anesthesia machines), reviews purchase requisitions for such devices and supervises their acceptance testing, PM, and repair. Ms. Zikherman supervises PM and repair services for electronic equipment and serves on SMIC's on-call/recall team.

Other SMIC staff members, with many valuable years of experience, contribute unique talents and expertise to the department. These include senior biomedical engineers Michael Doron, Simon Gerech, Lenworth Howe, George Martin, Michael Salts, Semyon Ullis, Stanley Wei; biomedical engineers Yefim Brayman, Michel Chery, Ruck Gilles, Boris Shamrokov; and precision machinist Randall Andronica. SMIC secretary Emma Johnson cheerfully keeps everyone on track.

Figure 6-11 Educational/Community Support. Senior biomedical engineer, Michael Doron, shown here constructing a test fixture, provided Brooklyn youth with a lecture on blood pressure monitoring as part of the Brooklyn Museum's *Big Adventure Program* for children, thus introducing them to the profession of clinical engineering.

Training

Continuing Education

The environment in which clinical engineering functions changes daily as new technologies such as telemedicine, robotics, and wireless-LAN are introduced into the clinical setting. In this dynamic field, continuing education is the rule. This is as true for SMIC's director (Soller, 2001) as it is for the most junior member of the technical staff. For this reason, SMIC staff are encouraged to participate in continuing education. Training is provided by SMIC (see Fig. 6-12), other departments within UHB, external sources such as independent companies, manufacturers, and vendors, in addition to self-study. When possible, supplemental funding is obtained through the union's continuing-education grants program.

Service Training

As new medical equipment is acquired, employee technical knowledge concerning operation, PM, and servicing must be updated. Whenever possible, service training is included in purchase requisitions and RFQs for new equipment. Service training benefits not only clinical engineering, the equipment maintainer, but also the equipment user each time SMIC is called to assist with equipment-related problems. SMIC staff also attend equipment-operator training provided by vendors for clinical users of medical equipment within the institution.

Safety Training

Employee right-to-know and safety training addressing the hazards encountered in the workplace is also provided. This subject matter includes bloodborne pathogens, hazardous materials, universal precautions (e.g., proper protection when entering patient-care areas, such as gloves and masks), environmental hazards, fire hazards, and a patient's bill of rights.

On-call/Recall Training

Formal on-call/recall training is provided. In addition, regular departmental meetings consider the latest operating-room practices and changes of which on-call staff must be aware to provide emergency services.

Figure 6-12 In-service Education. In-service education can be provided by manufacturers and vendors, as well as by clinical engineering staff. Here, Lab Supervisor, Luis Cornejo, provides training to other clinical engineers in the use of an automated ventilator tester. Such devices reduce the number of individual test instruments required by integrating several test functions into one device, thus reducing service time leading to more rapid equipment turnaround. Such education also helps to satisfy JCAHO training requirements for clinical engineering staff.

Facilities/Equipment

SMIC maintains electronic and electromechanical laboratories, a machine shop, an administrative area, and storage facilities. Adequate space is allocated for SMIC to perform its myriad functions and includes limited space to store new equipment, equipment awaiting servicing, equipment awaiting delivery back to the clinical user, and equipment sequestered because of suspected involvement in a patient incident.

SMIC's administrative area acts as the hub of activity. It directs visitors and clients to appropriate personnel, and houses all equipment-management files.

The laboratories for acceptance testing, PM, and repair, contain electrical power, suction, compressed air, secure gas tank storage, sinks, workbenches, test equipment, tools, and storage cabinets.

The machine shop, which is equipped with a drill, lathe, grinder and milling machine, and other useful devices, enables SMIC to perform emergency mechanical repair of damaged medical equipment; customize and modify equipment including crash carts (see Fig. 6-13); mount equipment, e.g., physiological monitors onto anesthesia carts; construct test fixtures; and provide research assistance.

Figure 6-13 Equipment Modification. Lab Supervisor, Luis Cornejo, and biomedical engineer, Ruck Gilles inspect a medication cart that SMIC modified to accept an electrical-outlet strip and retractable reel, oxygen cylinder, defibrillator, and an aspirator so that it can be used as a cardiac-arrest crash cart, which is brought to the patient's bedside for resuscitation during cardiac or respiratory emergencies.

SMIC is the central repository of all regulatory-related medical instrumentation history files, both active and inactive, for equipment that falls within its province. Its library maintains instrumentation technical manuals (e.g., operator, service, and applications) and equipment evaluations. Hence, SMIC is the first place to which one goes for information on patient care or patient-related equipment.

Ethics

SMIC adheres to the ethical code of the ACCE (see Chapter 130). Among other things, this code strives "to prevent a person from being placed at risk of injury due to dangerous or defective devices or procedures" to "work toward the containment of costs by the better utilization of technology"; and to "protect the confidentiality of information from any source." If it does not adhere to confidentiality, a department's credibility is soon lost. Confidentiality relates not only to patient information but also to medical equipment information.

Summary

The challenges of providing a full-service, in-house, clinical engineering program within a dynamic academic medical center and university teaching hospital setting such as that of Downstate Medical Center are formidable. The biomedical and clinical engineering services that are expected far exceed those of a nonacademic community hospital. To meet the challenges, sufficient clinical engineering and administrative staff who possess diverse expertise and flexibility must be available. The challenges are worthwhile and personally rewarding.

SMIC is proud of its past accomplishments, the example it sets, and the input it provides to the clinical engineering community at large. It looks forward to meeting future challenges within the exciting and stimulating environment of SUNY Downstate Medical Center and University Hospital of Brooklyn.

Acknowledgements

I wish to thank all members of SMIC's staff, both past and present, with whom I have worked over the past 24 years. It is through our daily interaction that the concepts presented here have been better defined.

In particular, thanks to: SMIC's associate directors John Czap (for his many years of dedicated service to Downstate) and Leonard Klebanov (for his expert technical consultation); SMIC's administrator Marcia Wilkow (who deserves special praise, often acting as a valued sounding board, and for suggestions to enrich publications such as this one); and SMIC's laboratory supervisors Luis Cornejo and Sophia Zikherman (for keeping SMIC running on a day-to-day basis despite the many challenges faced). By relying on each other over the years of our association, we have managed to push the boundary in the correct direction. I am proud to be part of their team.

Thanks also to: Senior associate administrator William Gerdes, who understands and values SMIC's services; Ernest A. Cuni, Biomedical Communications, SUNY Downstate Medical Center, for the photographs; my daughter Tobey for design of SMIC's Logo; and my wife Helaine for suggestions that improved the readability of this manuscript.

Regional Clinical Engineering Shared Services and Cooperatives

J. Tobey Clark

Director, Technical Services Program
University of Vermont
Burlington, VT

Regional shared service programs, which started in the 1970s, led to safer medical devices and health care technology application and lower support costs for small, community hospitals that did not have the volume to have an in-house department. Many of the clinical engineering programs in developing countries are being set up under the non-profit, shared services model which has proved to be an effective entry system for clinical engineering.

Although many of the programs evolved over time into for-profit companies or cooperatives in the United States, the general principles of sharing specialized services in a region still are practiced. Programs that continue to offer shared services have been successful because of proactive actions adapted to changes in the health care environment. The Technical Services Program (TSP) described in this chapter is one organization providing shared services as a nonprofit, independent organization. Features of this program are discussed in this chapter.

Introduction

The concept of sharing resources to serve health care in a state or region for the common good of the group fits in with the cooperative efforts that are necessary to provide patient-focused, integrated health care. A shared service is provided through the cooperation of

multiple institutions typically serving a certain geographic area. The purpose of shared service organizations is to meet the needs of the regional health care entities in the most cost-effective manner. Shared services allow the economy of scale that individual institutions might not have for low volume, large expense, or highly technical services (particularly regional rural-community hospitals). In the past, many specialty services have been administered in a shared service manner including laundry, blood banking, mobile imaging, and telemedicine technology.

A not-for-profit shared services entity may be part of a hospital cooperative, a hospital association, or university. For-profit shared services also exist. The for-profit kind can be truly a cooperative only when the profits go back to the members. Advantages of the not-for-profit is the enhanced credibility within the hospital community, achieved in part by the involvement of hospital administration via a governing board or advisory group that seeks improved quality and cost-effectiveness—not profits—as the motive.

Historical Perspective

Many factors led to the startup of regional shared service clinical engineering services. They included the electrical safety scare of the late 1960s; Joint Commission on Accreditation of Healthcare Organizations (JCAHO) standards changes; the general lack

of expertise of hospitals in the area of medical equipment safety and support; the prohibitive cost of developing full clinical engineering programs in most community hospitals; and the fragmentation of medical equipment support services.

Most importantly, clinical engineering is one area of health care services that are lucky enough to have a major benefactor to fund the start-up of cooperative programs across the United States. The W. K. Kellogg Foundation (Battle Creek, MI) funded regional clinical engineering shared services in the early to mid 1970s (Dodson and Latimer, 1975). The foundation was not new to funding shared hospital services as it had had success in funding management engineering programs in the past. The Foundation funded universities and hospital associations with grant money to start clinical engineering shared services in their state or region. Beginning in 1972, over \$3 million in funds were distributed, first to the Northwest Ohio Clinical Engineering Center (Toledo) and later to organizations in Arizona, California, Arizona, Hawaii, Illinois, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, North Carolina, Pennsylvania, Texas, and Vermont, along with the Emergency Care Research Institute (ECRI) in Plymouth Meeting, PA. Some of the early leaders of these programs include Burt Dodson of Carolinas Hospital Engineering Support Services, Malcolm Ridgway of Shared Biomedical Engineering Service, Frank Kane of Medical Instrumentation Systems, and Alex Schwan of Northwest Ohio Clinical Engineering Center. These programs primarily serve small to mid-sized hospitals. (See Figure 7-1.)

Other shared service programs developed from a variety of other funding sources. Initially, most programs were nonprofit tax-exempt corporations. The American Society for Hospital Engineering (ASHE) was the base for the Committee on Shared Clinical Engineering, which fostered networking between groups. Mike Brinkman of Hospital Maintenance Consultants was a primary coordinator who worked with the shared service organizations. Similar shared programs developed in Canada notably the Regional Clinical Engineering Service in Moncton, New Brunswick, which provided services for seven hospitals in the southeastern region of the province.

Today, clinical engineering programs starting in developing countries often model themselves after the shared service model. The Advanced Clinical Engineering Workshops (ACEW), conducted under the sponsorship of the Pan American Health Organization (PAHO) (see Chapter 70) and the World Health Organization (WHO), are presented by faculty from the American College of Clinical Engineering (ACCE) (see Chapter 130). Many of the participants in these programs are part of regional, multi-hospital or university-based shared service organizations in their countries.

Figure 7-1 Hospitals served by clinical engineering programs as categorized by bed size. From Dodson and Latimer, 1975.

Successful Implementation of Shared Service Clinical Engineering Programs

Although over 20 shared service clinical engineering programs were in existence in the 1970s, few remain, and almost none remains under its original charter. Some were turned into successful private companies. The shared service program organized under the Massachusetts Hospital Association is today Technology in Medicine <http://www.techmed.com/>. The Hospital Council of Southern California's Shared Biomedical Engineering Service is now MasterPlan, Inc. <http://www.masterplan-inc.com/>. Other programs ceased operating for a variety of reasons, and a few were bought out by biomedical maintenance companies.

New forms of shared programs operate as for-profit subsidiaries of health systems or cooperatives. Examples would include the following:

- Premier Inc., Clinical Technology Services <http://www.premierinc.com>, is collectively owned by more than 200 independent not-for-profit hospitals and health systems in the United States and operate under, or are affiliated with, more than 1,800 hospitals and other health care sites.
- Technical Dynamics, Inc. (TDI) <http://www.tdibiomed.com> provides biomedical and radiology equipment management, maintenance, repair, and clinical engineering support services in Virginia, Delaware, Maryland, and Washington, DC, operating under the auspices of Inova Health Systems.
- TriMedx Health Care Equipment Services <http://www.trimedx.com/> is part of Ascension Health, the largest not-for-profit health care system in the United States.

The shared service programs that remained were viable because of several key factors:

- A strong relationship with the state or regional health care organizations. Examples would include state hospital associations, hospital engineering societies, hospitals affiliated with tertiary care centers, and allied health groups;
- Regular communication with customers via meetings, educational events, contributions to nursing and other regional forums, and other interaction. Sponsoring and conducting seminars is one method. E-mail Listservs and Web-based newsletters are good tools to employ;
- Leadership to guide the programs through the hard economic times;
- Proactive program changes to embrace health care technology management—not just maintenance and safety. With the increased safety and reliability of equipment, limited reimbursement for health care services, and less prescriptive regulations, fewer resources could be allocated for maintenance and safety of biomedical devices. Clinical engineering shared service organizations needed to focus on assisting hospitals with the high-expenditure areas of procurement, technology planning, and liability;
- Focusing services on the areas where the dollars were spent in health care technology—radiology, clinical laboratory, and information technologies. A high percentage of the clinical equipment maintenance costs is devoted to expensive, high-tech imaging, laboratory, and clinical computer system);
- Adapting to fewer prescriptive requirements for inspections;
- Moving to fix price service in the age of managed care. Managed care contracts for health care services based on a fixed cost per patient. Many hospitals want the same

arrangement for their medical equipment service. Budgeting takes the risk and other unknowns out of financial planning;

- Justifying their existence and resources routinely and when large biomedical maintenance companies proposed to take over clinical engineering services. It was essential for shared services to know their costs on a unit/device basis, to be able to justify services, and to show cost savings for the institutions that they served; and
- The ability to use technology, creativity, and other resources to overcome the logistical problems associated with providing clinical engineering services in a typically rural region. Important elements include the availability of courier services for same-day shipping of parts and equipment, the use of the Internet for communications, interaction with the equipment-management database, education, and customer reporting, as well as specialty staffing such as imaging or dialysis service providers, clinical engineers and account managers located for fast response.

Technical Services Program

The Technical Services Program (TSP) <http://its.uvm.edu/> at the University of Vermont is the only shared service clinical engineering program that is still under the same governing body as it was when it was created by the Kellogg grant in 1973 (Clark, 1992). It operates as a nonprofit, independent organization. TSP, which is part of the Instrumentation & Technical Services Department at the University, is a group that is focused on providing community service through clinical engineering services and education—two key elements in the university's mission.

The program serves most hospitals in Vermont, 11 hospitals in northeastern New York, and four in northwestern New Hampshire through contractual arrangements. Many of these sites have resident biomedical equipment technicians who provide direct maintenance, service management, and communicate with users. A staff of three certified clinical engineers, 28 biomedical equipment technicians (BMETs) and additional specialists, managers, and support personnel make up the group. One clinical engineer (CE) supports the teaching hospital, Fletcher Allen Health Care; a second CE consults with community hospitals in New Hampshire and Vermont, and the third covers New York member hospitals. Twenty-two members of the BMET staff are in residence at hospital sites. A fleet of ten vehicles is used to travel to sites in a geographic radius 150 miles to the east, west, and south of the main office in Burlington. A Vermont Hospital Association-sponsored customer board oversees the program and meets quarterly to discuss services, costs, needs, issues, and future planning. This is a key element in the continued development of the program.

TSP has focused on all aspects of health care technology management. A strong effort is made to assist and participate with hospitals in the area of technology planning and acquisition to allow TSP to show its value as professionals assisting hospitals in assessing new technologies, providing guidance on equipment replacement, and in acquiring cost-effective and supportable equipment. In the latter function, TSP can provide significant input into including service training, tools, and documentation with purchase equipment to allow quality support regionally.

Another important element is education and communication with health care staff. Quarterly seminars (Figure 7-3), newsletters, educational participation in regional clinical and facilities engineering society meetings, and, of course, vocational training for university biomedical engineering students in the area of clinical engineering are important parts of continuation of this program (Figure 7-4).

Initiatives of TSP have included:

- Procuring a second grant from the Kellogg Foundation to develop the first IBM-PC-based equipment management system (Hospital Engineering Management System (HEMS));
- Partnership with local industry (Bio-Tek Instruments, now Fluke Biomedical) to develop biomedical test equipment;
- Using the service volume to develop contract-discounting and warranty service arrangements with major medical equipment manufacturers;
- Development of an independent, cost-capped maintenance insurance/group contract arm, Capital Asset Protection Partnership, for reining in service costs for imaging, laboratory, and other high-tech equipment; and
- Participating in a pilot program to replace the FDA's MedWatch reporting system with an Internet-based system.

Although the continued viability of TSP and other shared services depends upon the proactive measures the organizations take to adapt to the changing environment, the

8

In a modern hospital, most diagnostic, therapeutic, and rehabilitation activity is based on the extensive use of medical technologies. Between 1983 and 1987, in order to improve the quality of health care services, the Italian National Research Council (CNR) instituted a special project to develop new medical devices and new clinical engineering services. The project had three components, one of which, named ACMAGEST, concerned the assessment of in-house clinical engineering departments (CEDs) by means of the guidelines for their establishment (Donato and Bravar, 1987).

At the end of a widely coordinated activity, that over the years has interested a growing number of operating units (23), the analysis of clinical engineering services development was contradictory. In fact, if from one side, to the existing four services were added six more, from the other the implementation rate of CEDs in Italy was definitely too low to allow Italy to come alongside of the other developed countries. Moreover, when the subproject, ACMAGEST, was completed, CEDs implementation rate suffered another slowdown. Therefore, during the 1990s, because of a drastic financial cut requested by the Italian government, it was impossible to use the internal resources to optimize, the management of biomedical equipment. For this reason, outsourcing the management of the biomedical equipment to private companies became a viable alternative.

In spite of the events of the past, Italy is now slowly on the way to transforming clinical engineering from the sporadic, experimental, and episodic to a reality that will be numerically significant, consistent, and pervasive throughout the national health care scene. Although the number of Italian public hospital beds served by clinical engineering activities has been increasing over the last five years (+80.9%), the number of CE departments within Italian public hospitals has remained low. (Only 20% of total hospital beds are managed by CE.) Today, CE services performed by external private companies are increasing, and the amount of hospital beds served by internal CE departments are about 8%, as compared to 12% served by external private companies.

ITAL TBS activities in the National Health Care Service

ITAL TBS SPA is an independent, third-party service organization established in Italy in the early 1980s after the conclusion of the ACMAGEST subproject. Its main aim is to

regional, nonprofit shared services base of operation will always be an advantageous position for clinical engineering services.

Research Area of Trieste, CIVAB
ITAL TBS SPA
Trieste, Italy

provide and promote nationwide clinical engineering (CE) services in public and private health care organizations. The company has been ISO 9002- and EN 46002-certified since July 1998.

ITAL TBS began its activities in the Childrens Hospital IRCCS Burlo Garofolo of Trieste in 1992, assigning full-time technical personnel and giving qualified advice for procurement activities. Since then, the company has expanded its CE service throughout the Friuli-Venezia – Giulia Region. Since 1995, its activities have spread nationwide as it supplies CE services to more than 70 hospitals (Fig. 8-1) and manages over 80,000 medical devices.

The laboratories and headquarters of ITAL TBS are located in the Area Science Park of Trieste. The company's Center of Information and Evaluation of Biomedical Equipment (CIVAB) is located here and centers its activity on the collection and distribution of technical and financial information on biomedical technologies. The company has developed and enlarged the range of its offered services. It started with many contracts for the management of biomedical equipment in hospitals and it developed through the impetus of two projects funded by the Italian Ministry of Health. One project, carried out at the CIVAB Laboratories in Trieste, entailed the assessment of the costs of medical device technology. The other, called the SPERIGEST project, was done at the CREAS-IFC Hospital (which specializes in the field of cardiopulmonary care) of the Italian National Research Council (CNR) in Pisa. ITAL TBS always has cooperated in research project shifting the outcome of these in real services (Bravar et al, 1997).

To perform its technical services alone, ITAL TBS employs a staff of about 150 technicians with specific experience in the maintenance of biomedical equipment (Fig. 8-2). The staff is coordinated by 30 engineers, some of whom hold Ph.D.s in clinical engineering. In addition, about 50 technical and graduate personnel are employed in other sectors of the company.

In all hospitals where ITAL TBS operates, technical staff operates on a permanent basis inside the facility to ensure timely intervention and uninterrupted technical support of clinical work, which often is difficult or impossible to achieve with classical maintenance contracts with manufacturers or vendors of the technology. The company offers support services to improve the management of technology, either in terms of the safe operation of biomedical equipment already installed or in relation to aspects connected with the optimization of the maintenance and/or operating costs of these instruments. The range of services offered includes global maintenance of all biomedical equipment installed in

Diego Bravar and Teresa dell'Aquila

Figure 8-1 Geographical distribution of clinical engineering services, located inside hospitals, provided by ITAL TBS.

hospital facilities, assurance of compliance with safety regulations, acceptance testing of new devices, strategic planning with hospital administration for equipment acquisition, preparation of budget specifications for the procurement of biomedical technologies, equipment evaluation and selection, technical evaluation of contract bids, and analysis and monitoring of operating costs.

Preventive Maintenance. All maintenance is generally performed by ITAL TBS staff who are permanently based in the health care facilities involved in the service. Preventive-maintenance servicing is carried out on a regular basis according to the type of appliance and the specific servicing schedules drawn up by ITAL TBS, with extensions where the service and maintenance manuals require. The company technicians carry out planned maintenance according to a detailed schedule established upon acceptance of the equipment. The service is based on operational requirements of health care facilities using the same equipment and on tried and tested schedules.

Unscheduled Repair. Since this service is usually carried out by ITAL TBS technicians who are permanently based in health care facilities, it guarantees prompt interventions and the almost immediate correction of a large percentage of malfunctions, which minimizes machines' down time. Intervention is guaranteed to take place within four hours of the receipt of a service request (unless otherwise specified in the contract). The computerized management of spare parts provides a complete, updated picture of the situation in general and available parts in particular.

Electrical Safety Testing. Electrical safety testing consists of either visual inspection or measurements of biomedical electrical equipment to verify compliance with the requirements of the CEN/CENELEC European standards. The objective is to inspect all electrical equipment found at the client hospital or clinic.

Quality Control. Normal use of biomedical equipment can lead to perceptible deterioration in performance, caused by wear and tear on mechanical and electronic components or, more frequently, by improperly calibrated or aligned equipment components. From the acceptance test onward, it is therefore advisable to conduct a series of tests, based on standardized criteria, designed to ascertain the performance level of a medical device.

Inventory Management. Inventory management establishes the numerical and financial value of the stock of biomedical equipment held by the health care facility. Data are analyzed according to specific statistical processes, such as type of appliances installed, distribution per purchasing year, and obsolescence index.

The Clinical Engineering Consultation and Acquisition Plan. For local health services, the supply of medical equipment that is needed to benefit from the new technologies must be acquired on the basis of a careful analysis of the many factors involved in the use of the technologies themselves. This analysis ensures the correct allocation of resources and avoids the purchasing of unnecessary or even nonproductive equipment. To make cost-effective acquisitions for health care organizations, any new medical technology must be chosen based on the knowledge of its performance, value, and availability. The determining of the correct ratio of equipment stock is carried out by ITAL TBS S.P.A. by means of a specific operational procedure that involves the comparison of total equipment stock with that identified in other developed countries in terms of ratio of this to their respective gross domestic product (GDP). The analysis is also based on the preliminary gathering of specific technical, clinical, and administrative information regarding the requested equipment. In order to ensure the appropriateness and sustainability of the proposed

Figure 8-2 Personnel of ITAL TBS.

equipment, the selection of the make and model takes into consideration factors such as operating and running costs, system requirements connected with the installation of equipment, and analysis of alternatives.

Software for the Management of Biomedical Equipment

Since 1988, ITAL TBS S.p.A. has been producing information systems in the field of clinical engineering. Over the last ten years, the company has created a large database, from the activities it has monitored, which includes 80,000 medical devices, over 100,000 maintenance tasks, and about 40,000 electrical safety and quality assurance surveys. Starting with this large and valuable information base and utilizing the CIVAB coding system of medical devices that ITAL TBS S.p.A. developed for the Italian Ministry of Health, the company built an information system integrating technical, economic, and performance data.

ITAL TBS successfully built a complex information system that began operations in late 1998. Since then, it developed an installed base that now serves 30 sites, ranging from complex, multihospital public sites to medium-sized public and private clinics.

The databases are functionally and geographically separated according to the needs and communications costs constraints, while highly integrated by means of distributed and replicated database techniques, to fully achieve the goal of global activity management. The user has the ability to update and access local and global data with the most appropriate user interface ranging from a Windows-based client/server application for data entry to Internet-based data publishing for management at different levels and for customer analytical and synthetic reporting. All available legacy data was taken into account in order to build a system that would be able to supply useful steering and to control pieces of information from the beginning of operation.

The integrated informative system S²C (Figure 8-3) performs the following functions:

- The recording of each action of corrective maintenance. For each medical device, a computer version of the service manual is available.
- The recording of each action of preventive maintenance. For each medical device, the maintenance protocol is available, with information about the necessary instrumentation and the average time necessary for the action. The system promotes the preparation and performance of a plan of preventive maintenance for a given device.
- The management of the electrical safety tests according to the CE guidelines
- The management of the instrumentation calibration

The Italian Observatory of Medical Equipment and Devices

In order to improve the quality of health care services, the Regional Health Authority of Friuli-Venezia Giulia (a northeastern region of Italy) began an original, three-year program called "Observatory of Medical Devices" (ORT) in 1992. The program's aim was to assess and monitor the existing biomedical equipment in all regional hospitals and to monitor the flow and the expenditure for the most important categories of medical devices (e.g., diagnostic reagents and X-ray films). The ORT program was operated by the

CIVAB of ITAL TBS at the Area Science Park of Trieste (Bravar et al., 1995). Concurrently, some Italian regional hHealth authorities (Friuli-Venezia Giulia, Veneto, Emilia-Romagna, Lombardia, Lazio, Sicilia, Trento, and Bolzano) made an agreement with the Area Science Park of Trieste in order to offer advanced services in the field of biomedical technology to each of their public health structures.

In 1997, the Italian Ministry of Health financed a three-year project of the Regional Health Authority of Friuli-Venezia Giulia called "National Observatory of Prices and Technology" (OPT). The aim was to increase the available instruments to all public health structures providing technical and economic information for the more efficient management of medical devices (Bravar et al., 1997). The OPT program, which has been operated by ITAL TBS CIVAB in the framework of an agreement between the Regional Health Authority and the Area Science Park, has developed the following products:

1. Technical bulletins on 36 different categories of biomedical equipment available on the national market (18 issues/ per year)
2. A national database of medical equipment and devices and their suppliers, storing technical and commercial data
3. A national coding system (CIVAB Code) of medical equipment and devices, based on the standard ACMAGEST code
4. A monitoring system of medical equipment and devices purchase prices, based on data collected from a network of 20 Italian regions
5. Remote consultation (via the Internet) of technical information and purchase prices of medical devices in the National Health System

The device and supplies cost-monitoring system has been activated for some of the most important groups of medical devices: 40 different categories of biomedical equipment, representing more than 60% of the market of medical device products in Italy, including diagnostic reagents, X-ray films, hemodialysis filters, implantable pacemakers, angiographic catheters, and knee and hip joint prostheses.

At the end of the activity, the national coding system (CIVAB code) for medical devices and equipment and the 36 different technical bulletins of biomedical equipment, including a data sheet on more than 1500 models, has been sent out to about 350 Italian Public Administration of National Health Services. The national database of medical equipment and devices and their suppliers (Figure 8-4) consists of more than 26,000 different models of biomedical equipment, 35,000 different models of medical devices, and more than 3,500 addresses of suppliers. The OPT database contains technical and economic data for about 19,000 biomedical devices purchased in 40 Italian Public Hospitals. A password-protected web site, where OPT data and code and analysis of price data are available for all of the Italian Public Hospital Administration. At the end of the project, detailed and up-to-date information about technical and economical parameters of biomedical products is available via a network involving regions and their public health structures.

The Portal for E-Management of Medical Devices in Italy

ITAL TBS, thanks to its wide experiences as a Clinical Engineering Services Company and as manager of the Italian Observatory of Prices and Technologies, is developing a web portal to offer high-quality information about biomedical devices. The model of the "Electronic Office for Medical Devices Management and Procurement" is based on the transfer of the offline core competencies of ITALTBS in an online context: The customer will be able to obtain the technical specifications of equipment, after answering a set of questions about his clinical needs and, more generally, about his activity. In particular, the available services are free-access information, online consulting, and online auction. (See Figure 8-5.)

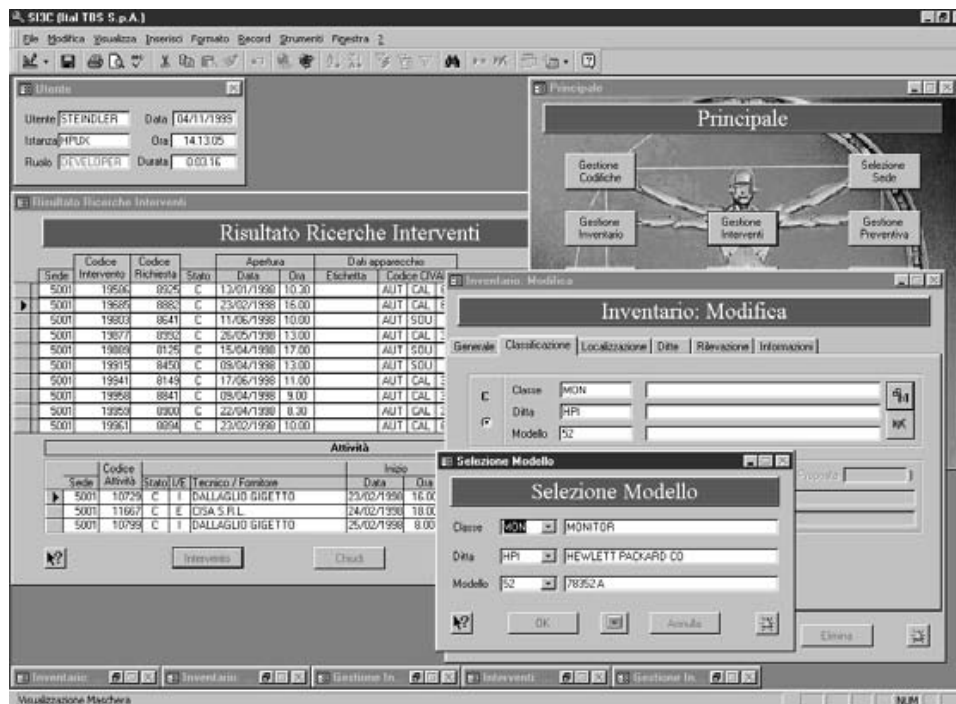

Figure 8-3 S²C main application user.

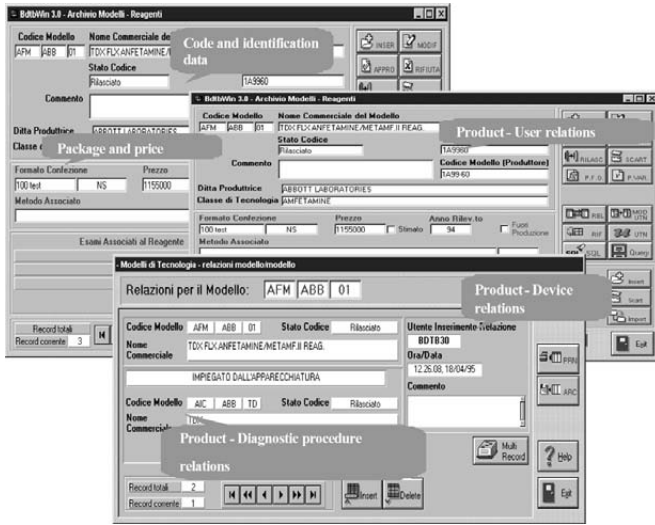

Figure 8-4 The national database of medical equipment and devices.

Available at the first level are the principles of operation for the most important medical equipment, the most interesting news from the health care field, discussion forums on topics of great interest in this field, workshop and congress, and news (product and actions) from manufacturers. To access the second level, the customer must be registered as a client. At this level, he finds detailed technical features and data for each product as well as informative sheets on biomedical equipment. He is guided by a list of questions to the technical specifications of the device needed. The portal shows all of the commercial products and the median price for a particular configuration, and it lists the minimum technical-specifications requirement. On demand, the specifications can be included in a specific document that is necessary for a tender of public administration.

The third level is the organization of inverse auctions, where the technical specifications could serve as a pre-qualification and the bidders could make their economic offers online, lowering the price in order to win the bids. The complete model of the web portal

for the “Electronic Office for Medical Devices Management and Procurement” is described in Figure 8-5.

The SPERIGEST Project of the CNR

Since 1995, within the activities of a research project called SPERIGEST of the Italian Ministry of Health and the Italian Authority of the Region Tuscany, the CNR Hospital of Pisa (CREAS-IFC), which is a Hospital Cardiovascular Institution (including the Clinical Physiology Institute of Pisa and the Apuano Pediatric Hospital), implemented the integrated management of its services. The goal of SPERIGEST was to establish the guidelines for the optimized management of a cardiovascular hospital by means of a new model for the management of biomedical equipment and the implementation of integrated software systems for the management of clinical data, signals, and images. Furthermore, in order to optimize the management of biomedical equipment and information systems belonging to the National Health Care Service, a subproject of SPERIGEST, dedicated to clinical engineering, had the goal of ensuring cost-effectiveness and safe and appropriate technology management of all equipment involved in the Hospital’s operation. The CREAS-IFC outsourced to ITAL TBS and to the software company INSIEL a subpart of the project including the clinical data, signals, and images; administrative data integration; and the management of biomedical equipment.

The Clinical Engineering subproject of “SPERIGEST.” It was a unique opportunity to define the rules within which private companies can promote the diffusion of clinical engineering services at the national level and to redefine the role of CE services in the field of information technology. To ensure cost-effectiveness, safe and appropriate technology management of all the equipment involved in hospital administration, during 1995 the CNR-IFC enlisted ITAL TBS to established CE services. Working out of 8 laboratories, it covers 11 hospitals located in Northern Tuscany for a total amount of nearly 2000 beds and 8000 devices with a capital value of about \$60 million.

The ITAL TBS staff of the SPERIGEST project included: 1 biomedical engineer as Project Director, 3 clinical engineers, 16 biomedical technicians, 1 biomedical engineer for economic analysis, 3 computer technicians, and 2 administrative and other biomedical engineers for medical computer science. During this period, the CNR budget for corrective maintenance (full risk) of biomedical equipment decreased from 7% of the substitution value of installed medical equipment in 1994 to 5% in 1998, mainly because of the clinical engineers intervention and extensive intervention to integrated information (Fig.8-6). SPERIGEST has been useful in analyzing the set of activities to be carried out by specialists working inside hospitals. Table 8-1 shows the percentage of effort dedicated to the various project tasks.

SPERIGEST has shown how a CE service can dramatically reduce the time for resolving problems with medical equipment, as shown in Figure 8-7.

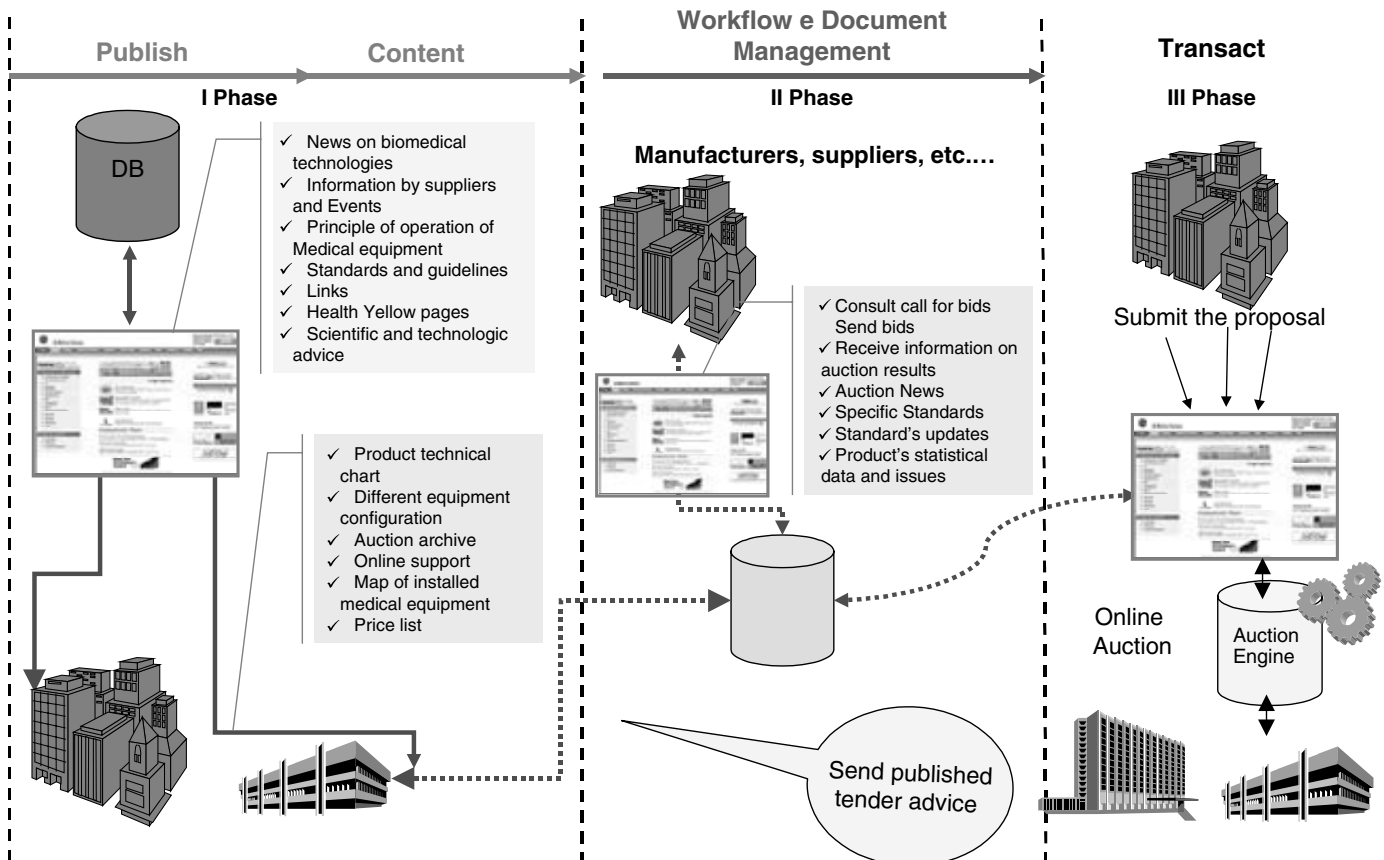

Figure 8-5 Electronic office for medical device management and procurement.

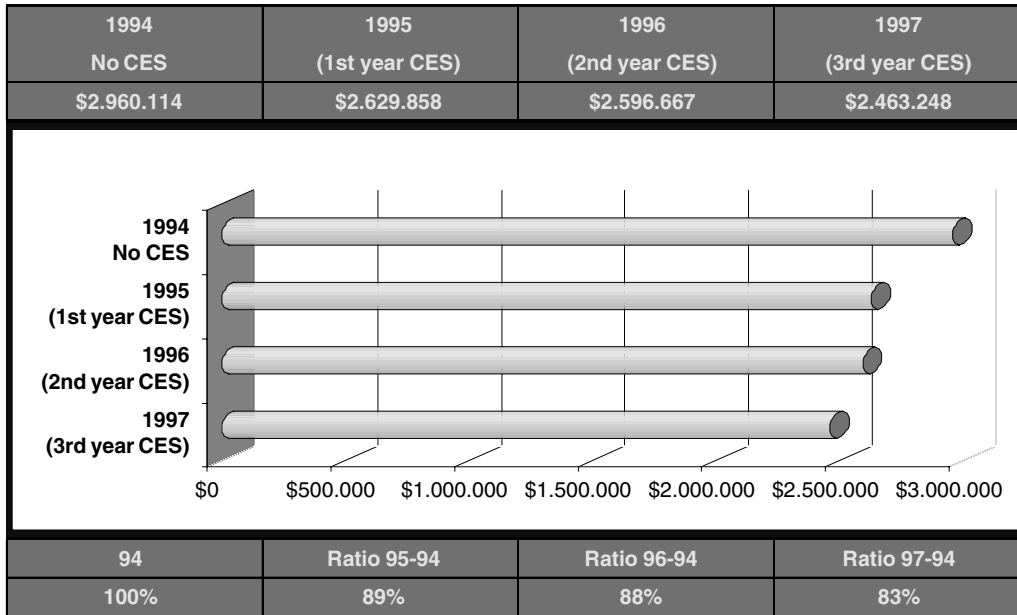

Figure 8-6 Budget for Italian CE service in SPERIGEST.

In conclusion, the outsourcing (total or partial) for clinical engineering services is the better solution for the health care system. The clinical engineering service company represents the better choice in terms of cost-benefit ratio.

“SPERIGEST” software for data, signal and image integration. The principle that has inspired the software-systems structure of SPERIGEST is the maximum integrability and flexibility with different networks and software. The data flow for the integration is based on 3 archiving levels: (1) administrative, (2) clinical, and (3) multiplicity of local archive named *functional island*. See Figure 8-8.

The first two are central. The functional island is a more defined subsection with its own archive and specific software for diagnostic laboratory as hemodynamic, nuclear medicine, CT scanners, Holter, and digital radiology. The integration of these archives is made by two different methods: middleware and Web. Using standard Internet browsers the web permits the view of clinical and administrative data. The total system connected 7 different sites (both clinic and administrative) managed by 14 nets (Ethernet, Token-Ring, MAN, Serial), 8 routers, and 60 clients.

Inside the SPERIGEST project, ITAL TBS has integrated the software of the cardiology departments of the Hospital (made by CREAS-IFC) with administrative software (made by INSIEL). This integration makes possible the online analysis of health care activities and their costs for each patient. At the end of the project, the SPERIGEST programs are working routinely for hospital admission and discharge, ambulatory reservation, Electronic Medical Record integrated with 6 different diagnostic laboratories and the administrative system, and web tools for hospital management.

Medical Information Technology and Telemedicine Project

ITAL TBS, in the Cardiovascular Hospital of the CNR of Pisa, by using the SPERIGEST project, data, signals, and images have been integrated only for the cardiology departments. Furthermore, ITAL TBS acquired the Austrian company PCS that has already developed and installed, in about 50 Austrian Hospitals, SW (PATIDOK™) for data, signals, and images integration for all hospital departments.

PATIDOK™ is a state-of-the-art hospital information management system that has proven its worth over the past 12 years as highly specialized, user-friendly software that can be configured to satisfy any individual requirement. As a universal program for processing the full range of internal and external workflow processes of health institutions, it embodies intelligent software with impressive gains in application. The clear and simple graphical user surface, the user-specific configuration/limitation of the system, and the tried-and-trusted user guide through the application of the system ensure short training times, a high degree of user acceptance, and the avoidance of application errors.

Many institutions, such as hospitals and clinics, want to organize their internal procedures and their communication with extramural institutions as efficiently as possible. IT

systems are meant to organize and accelerate procedures, to rapidly provide needed information, and to collect desired data completely and easily. The application of these systems should be as easy as possible, should guide the user, and should be perfectly adaptable to internal procedures.

PATIDOK™ meets all of these everyday organizational requirements. It is a workflow system that can be individually configured and thus has been able to control workflow difficulties in the health care sector for many years. Starting from the experience of the SPERIGEST project along with PCS’s experience in the Austrian market, ITAL TBS aims to develop integrated services of clinical engineering and medical information technology nationwide.

ITAL TBS founded the Second Opinion Italy, a telemedicine company in partnership with Second Opinion BV, a worldwide leader in these services. The service enables the reception of an additional medical opinion provided by specialist physicians in leading American hospitals such as Stanford University and UCSF (University of California San Francisco), just few days from the request.

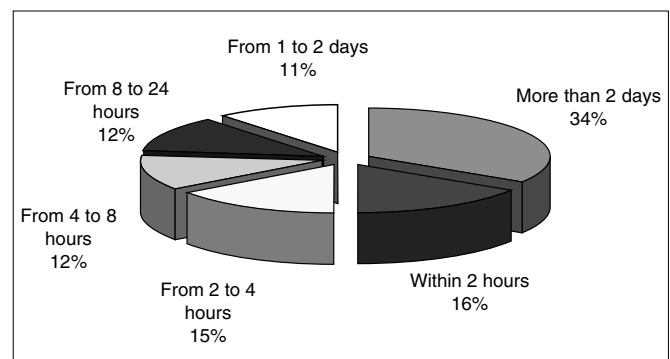

Figure 8-7 Resolution time for manufacturers (top) and for CE services (bottom).

Table 8-1 Distribution of workload dedicated to various project tasks

Compliance with safety standards	29%
Corrective maintenance	60%
Preventive maintenance	8%
Quality control	2%
Purchase consulting	1%

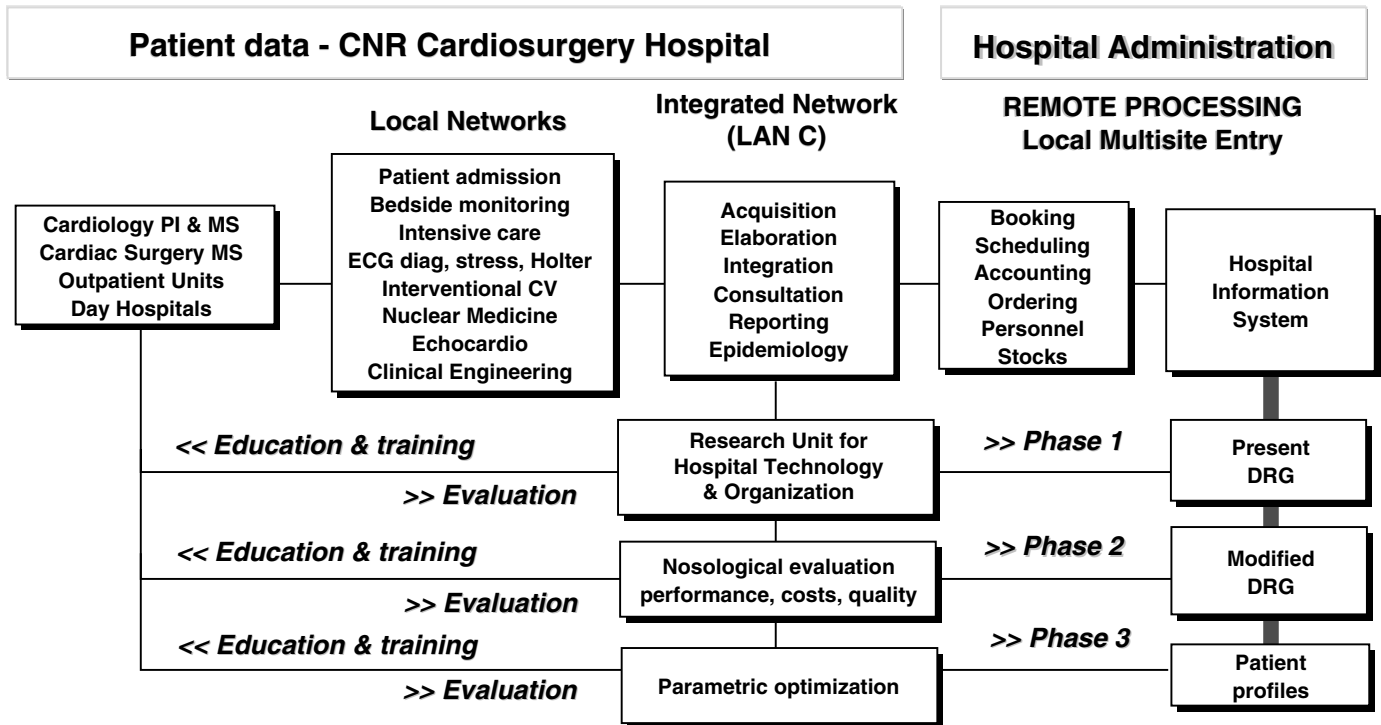

Figure 8-8 SPERIGEST: Clinical-Technical-Administrative integration of hospital resources.

In order to access the service, the user must forward just the medical record to the operational center, located in Milan. The record is digitalized there and forwarded to the specialist. With Second Opinion Italy, ITAL TBS aims to make available a very simple, but innovative, telemedicine service in order to deliver remote care to patients, combining communication technology along with medical expertise.

in this way. The Clinical Engineering Service Company represents the best choice in terms of cost/benefit ratio since the process of integration starts from the biomedical equipment. Then, it is possible to join the know-how and the expertise of clinical engineering with information technology expertise.

Conclusion

The quick evolution of biomedical equipment and information technology together with the raising need of integration of data, signals and images in the hospital produce the need of specialized expertise in computer science and clinical engineering. The health care process is complex. The management tools to make strategic decisions depend on the quality of information. The information for health care service management is generated from two different systems: the administrative system and health care medical record. Information technology should play a large part in the integration of these two systems. The partial outsourcing of the integration process and further operations, including clinical engineering services, is the solution of choice to let health care institutions deal with the more appropriate clinic activities only. A full custom solution can be easily achieved

Clinical Engineering and Biomedical Maintenance in the United States Military

Joseph P. McClain
Gilbert, AZ

The biomedical maintenance business area presents significant opportunities to reduce costs through regional cooperation and exploration of alternative maintenance management strategies. Maintenance activities present a substantial cost center for most medical facilities directly through labor and maintenance contract costs and indirectly through equipment acquisition and life-cycle management. Maintenance operations are predominantly facility oriented, with regional or area maintenance activities limited to within service (i.e., Army, Navy, Air Force, Marines, and Coast Guard) lines. Maintenance services that exceed in-house capabilities routinely are outsourced through local contracting.

A regional approach to biomedical maintenance services is consistent with other significant changes in this business area. Maintenance functions are being broadened and deepened into the discipline of clinical engineering. The field of technology assessment and management is being formalized and integrated as a core competency of clinical engineering. Clinical engineering and medical equipment management functions, systems, and processes are assuming renewed significance in the overall management of health care operations as the entire medical logistics field becomes more synergistic and complementary.

Opportunities for Regional Partnerships

Regional opportunities for clinical engineering and biomedical equipment management include the following:

- Shared services and expertise
- A unified approach to technology assessment and equipment life-cycle management
- A unified approach to levels of service
- Shared training;
- Regional contracting for maintenance services;
- Equipment standardization; and
- A unified approach to alternative maintenance strategies, such as risk-based maintenance and *Prime Maintainer* contracts.

These opportunities come with notable challenges. Previous efforts to standardize equipment at the military health services (MHS) level have not been successful in achieving clinical acceptance. Centralized contracting for maintenance services have had uneven success in reducing costs. Differences in service culture and business processes, as well as concerns over the effect of change of jobs and independence, present further challenges that need to be addressed.

TRICARE, the U.S. military's health care system, is patterned after civilian-sector health maintenance organizations, making it in effect the only nationwide managed care system in the U.S. Each TRICARE region or regional business office should establish a subcommittee or process action team of clinical engineering leaders to develop cooperation and business process improvements. Results of these team efforts should be tied directly to capital-equipment acquisition, developed and implemented by the command and local regional contracting. One approach is for teams to collect data on maintenance cost centers, identify high-cost activities, and develop management strategies to achieve the goals of the program. Typical high-cost centers include the following areas:

- X-ray systems
- Laboratory equipment
- Anesthesia equipment
- Patient-monitoring systems
- Fiber optic scopes
- Radiology Digital Imaging Network-Picture Archiving and Communications Systems (DINPACS) or Medical Diagnostic Information System (MDIS)
- Area maintenance support
- Training
- Annual maintenance contracts
- Repair parts

Regional Management Strategies

Regional clinical engineering offers various improvements over the current model of facility-centered maintenance operations. National trends indicate that savings are likely in the following three areas:

1. Consolidation of maintenance services into hub-and-spoke service relationships
2. Regional consolidation of contract maintenance services
3. Alternative approaches to traditional maintenance strategies

Some categories of regional opportunities are emerging as the Department of Defense (DoD) further refines its logistics-support capabilities. For example, Army, Navy, and Air Force activities across the MHS are beginning to share responsibilities for training and developing a tri-service cadre of biomedical equipment technicians. In some cases, Army and Navy activities are using Air Force assessment standards. This cross-pollination is strongly encouraged—it will build a stronger clinical engineering community and will enhance the contributions of that community to the MHS at large.

Regional/National Contracts

Contractor services are an essential adjunct to DoD's in-house maintenance capabilities. Contractors provide more specialized maintenance capability than DoD can affordably train and retain. Contractors allow DoD to acquire and support a broader range of equipment types than otherwise would be possible. Contractors permit increased flexibility in the types and frequencies of maintenance services. Not all contracted services are efficient, however. When separate maintenance contracts are negotiated and administered locally for each DoD treatment facility, service prices might be higher, contractor responsiveness may be reduced, and internal overhead pertaining to award-and-administer contracts is much greater. Individual facilities do not always have the expertise to develop, award, and administer the sophisticated contracts that are needed to obtain today's high-tech biomedical engineering services, but within most DoD TRICARE regions, the expertise does exist.

Maintenance service contracts are developed through statistical averages and expected mean time between service activities for particular equipment types. Regional contracts allow vendors to spread risks across a larger equipment pool and result in more cost-effectiveness than is the case with local contracts. Proven cost savings can range from 10% to 30%, according to prototype programs underway in DoD. Regional maintenance contracts also may allow consolidation of exchange items to provide float while services are performed and permit the consolidation of contractor-owned repair parts and test, measurement, and diagnostic equipment (TMDE) regionally.

Managing Levels of Service

Service response standards can be a significant contributor to maintenance contract costs. The cost of 4-hour service response 24 hours per day, 7 days per week will be significantly more expensive than more liberal standards. A regionally coordinated approach to service levels may reduce costs by providing a more sophisticated approach to the development of Statements of Work and applying a more analytical risk-benefit assessment for equipment to be covered. In other cases, additional risk may be tolerable in an area if equivalent services or equipment are available in the region. Opportunities may exist for shared or back-up support for first response, allowing contract-service-response requirements to be reduced.

Prime Maintainer Contract

Some service organizations are broadening their offerings to provide Prime Maintainer services in which they provide maintenance services that otherwise would be outsourced to multiple equipment maintainers. Under the Prime Maintainer concept, a single service organization provides turnkey support, usually under a negotiated fee schedule, prospective warranty program, or on a capitated basis. Prime Maintainer programs usually allow the in-house clinical engineering organization to enhance its own technical expertise by giving them first-look rights to service equipment or even an opportunity to be reimbursed by the Prime Maintainer for services provided in-house.

For remote sites with low equipment density or with little or no maintenance staff, credit cards, rather than in-house or annual contract support, may be a cost-effective solution. Credit card use must have well-defined controls, including maximum allowable ceilings, prohibitions on certain equipment items, and assurances that they will not be used when other services are available.

The most effective maintenance operation combines the benefits of regional consolidation with the flexibility and responsiveness that is available through other means. It is important to find the right balance among the various options on the maintenance continuum.

Time and Material versus Annual Contracts

As a variation of the Prime Maintainer concept, the in-house management of preventive maintenance and repair services on a time-and-materials (T/M) basis (rather than an annual service contract) may provide cost savings. This approach may be advantageous particularly when there is potential for in-house maintenance support from elsewhere in the region, or when the equipment or service is available.

Risk-Based Preventive Maintenance

Significant savings can be achieved by accepting fewer preventive maintenance or calibration services than are traditionally used. This approach is supported by guidance that indicates health care systems may reduce preventive services by evaluating each generic type of equipment, performing a risk analysis, and matching an appropriate maintenance response. Risk analysis is ongoing and involves continuing adjustment of maintenance frequency, based on gradually accumulating maintenance experience, changing maintenance practices, and technology insertions and improvements. Much of today's equipment is highly reliable and engineered for increased time between preventive services and inspections. In addition, self-diagnostic or remotely diagnosable equipment permits diagnostics or repairs to equipment components without on-site service. Preventive maintenance services—risk adjustment requires more detailed analysis than simple scheduled services. Preventive maintenance is enhanced when equipment density is sufficiently high to spread risk across a larger number of equipment items.

Department of Veterans' Affairs Repair Services

Some DoD facilities (Walter Reed Army Medical Center (WRAMC) in particular) have realized significant savings by using the Department of Veterans' Affairs (DVA) repair facility in Chicago to repair fiber-optic endoscopes. These devices traditionally have been sent to their original equipment manufacturers (OEMs) for repair to ensure quality. Clinicians at WRAMC have been unable to discern a difference between repairs performed by the DVA and the OEM. The DVA cost has been 30% less, with excellent service turnaround times. Regional economics may provide even more advantage for such services. In this example, fiber optic scopes account for a large amount of costs. A regional evaluation of alternative sources, or a regional approach to contracting for such services, can bring these costs down. Another factor that affects costs for scope repair is the cyclic arrival of new medical students or residents in larger facilities. Experience has shown that specific training targeted to these individuals can significantly reduce damage to these instruments, thereby reducing repair costs.

Walter Reed completed a pilot program to evaluate the DVA Durable-Repair Program, using the DVA repair facility in Chicago for the repair of fiber-optic scopes. During fiscal year 1999, documented savings were \$124,000, with the average individual repair cost reduced by 35%. Using the DVA improved average turnaround time by 44%.

Equipment Standardization

The standardization of medical equipment may provide significant cost savings throughout the equipment life cycle. A regional approach to equipment acquisition may provide more favorable terms and prices and also may reduce costs for training and maintenance. A prerequisite for effective equipment standardization is a thorough, broadly accepted equipment-requirements determination process, such as the technology assessment and requirements analysis (TARA) process that is used to develop Army requirements for radiology and laboratory equipment. Regions are encouraged to review the current TARA process and to find ways to use or adapt their equipment standardization.

Certain equipment categories lend themselves especially well to standardization because of their high cost, high density, relative criticality, and performance according to pre-existing commercial medical standards or degree of integration. These categories will provide the primary standardization targets for DoD health care regions during the next round of regional operations. Candidates for standardization include the following:

- Equipment approved for use on Air Force medical evacuation aircraft (patient-movement items (PMI))
- Imaging equipment, including digital imaging, ultrasound, and other diagnostic imaging product lines
- Endoscopy equipment and other minimally invasive surgical or diagnostic items
- Physiological monitoring systems, especially integrated patient-monitoring systems; and
- Laboratory and diagnostic equipment, especially HL7-compliant computer integrated systems.

Hub-and-Spoke Services

By forming regional clinical engineering activities, logistics leaders can create hub-and-spoke maintenance organizations that pool technical expertise, TMDE equipment, repair parts inventories, and other assets that otherwise could be distributed unevenly among a region's facilities. The regional, tiered approach to clinical engineering concentrates

highly technical and increasingly scarce clinical engineering staffs at the regional level. It permits implementation of the most effective training, cross-utilization, and professional development patterns within and between regions. It will permit the substitution of in-house, hub-owned, clinical engineering staffs instead of expensive, seldom-used services contracts at spoke locations. Finally, it provides the most effective regional visibility of equipment density, utilization, repair record, and modernization needs, all of which are consistent with the shift to technology-assessment roles for DoD's emerging clinical engineering organizations.

More collaboration is possible when DVA facilities are included in regional hub-and-spoke or other collaborative arrangements. DoD's facilities have a much different geographic distribution, with a tendency toward southern states and a concentration of larger medical centers in or near urban centers. DVA facilities, on the other hand, tend to be concentrated in the northeastern United States, and most are not located in urban centers, thus suggesting opportunities for mutual benefit to DVA and DoD. Each organization potentially can provide maintenance coverage for the other in areas where assets are spread thinly.

Technology Assessment and Requirements Analysis

In an environment of constrained resources, it is imperative to apply sound commercial business practices to capital-investment equipment programs (procurement dollars, equipment costing greater than \$100,000). The decision makers at the Lead Agent and Military Treatment Facilities (MTF) level must have viable means of acquiring the management information to effectively balance dwindling resources against clinical requirements. The ultimate goal of the TARA program is to establish a standardized methodology for assessing, planning, and pursuing the acquisition of technology within Health Affairs.

The TARA mission is to provide decision makers with the management information that is necessary to making informed decisions on the technology resources that are required to accomplish business-plan missions and to optimize clinical outcomes. This goal is accomplished through an unbiased assessment of radiology and laboratory functional departmental operations. A TARA consists of an assessment of requirements, current equipment, and operations as they relate to the equipment and clinical operations. Clinical issues are reviewed by the service clinical consultant/doctor or representative, and equipment issues are assessed by clinical engineers, medical physicists, and maintenance officers. The results of this assessment are provided only to the requesting facility and their respective lead agent. Trends and command-wide management issues discovered during these assessments will be presented to Health Affairs to assist in policy development and strategic planning. No specific reference will be made to issues at individual facilities except under extenuating circumstances, such as serious safety or risk management issues, or with the permission of the facility.

With Lead Agent visibility by tri-service regions, the return on investment is expected to be substantial. Such a program will assist in standardizing Health Affairs equipment and sustainment regionally, allow for seamless integration of technology, augment the tri-service equipment budget for high-dollar items (i.e., saving money with multi-system buys), and attempt to increase clinical availability and costs.

The Army has identified a cost avoidance of approximately \$70 million over the life of the program and expects that this figure will double (at a minimum) by conducting TARAs on a tri-service regional basis. This cost avoidance is recognized by confining high-dollar equipment purchases to equipment that is needed and technologically relevant in military hospitals and clinics.

In addition, by conducting TARAs regionally, other costly issues such as clinical resource sharing can be resolved. For example, consider Army Hospital A and Air Force Hospital AF, which are located within 45 miles of one another. Based on a TARA assessment, Hospital A has three radiologists with a workload for only 2.2, and Hospital AF has two radiologists with a workload for 2.5. Hospital AF sends remaining exams to a civilian group at a cost. The TARA would recommend that one of the Army radiologists share time with the Air Force facility, in return for support in other areas, thus decreasing costs and overhead for both facilities. The Army's TARA team is working with the DVA and plans to incorporate it into regional issues where relevant and cost-effective.

The Transition from Medical Maintenance to Clinical Engineering

The MHS has been in the lead on medical maintenance issues for decades, and continues to set the standard as the profession is transformed from a maintenance orientation to a clinical engineering orientation. As defined by the American College of Clinical Engineering (Bauld, 1991), a clinical engineer is "a professional who supports and advances patient care by applying engineering and management skills to health care technology. Clinical engineers manage personnel, finances, instrumentation, and projects to promote the safe and cost-effective application of technology."

Clinical engineering is a necessity for the complex, regionally based health care systems of the future. The growing complexity of medical technology means that sophisticated equipment, software, and telecommunications systems must be integrated and interoperable. Clinical engineers will participate in the assessment and management of all health care technology throughout its acquisition life cycle. TARA of equipment utilization and needs will ensure deliberate management of clinical technologies and match technology capabilities with health care needs. Clinical engineering operations will be tightly linked with capital and expense equipment acquisition, facility design and management, and maintenance.

As with other logistics disciplines, the emergence of clinical engineering heralds an important change for biomedical equipment maintenance and its place in the MHS.

Increasingly, equipment maintenance is an integral part of a regional, tri-service, managed care strategy to obtain the maximum possible yield from all of a health care system's assets. Clinical engineering is one of many new tools available to logisticians as they seek to define and enhance their role in the MHS and the TRICARE system. The many new directions that are available for clinical engineers fit seamlessly with the other management tools now being used to transform military health care.

10

The primary driving forces of change in health care are technology, social and political referendum, and market economics (Bronzino, 1992). Changes in available and applied technology in turn affect the responsibilities of persons maintaining and acquiring that technology (Babcock, 1992). In health care, clinical engineers have duties and responsibilities covering a broad range of activities that relate to medical equipment and medical equipment technology (Feinberg, 1986). The clinical engineer is in a position to be the gatekeeper of medical technology. The health care landscape is definitely changing with some areas left barren and some areas of new growth. This environment of change provides several opportunities for career and personal growth in the clinical engineering profession. This chapter will examine traditional, recently acquired, and future duties and responsibilities of clinical engineers.

Traditional duties and responsibilities are related to equipment maintenance. Historically, these duties are a result of the microshock scare of the early 1970s. With large megahospital systems emerging or consolidating in the early 1990s, the need for medical-technology management arose creating several opportunities for clinical engineers. Telemedicine, virtual instrumentation, and the Internet offer still more opportunities for clinical engineers in the near future.

Duties and Responsibilities

Clinical engineers have responsibilities in two broad categories: technical expertise and management. Clinical engineering departments in smaller medical facilities typically do not have the resources to support medical technology assessment programs or functions associated with a chief technology officer. Therefore, clinical engineers in smaller facilities generally have more traditional duties and responsibilities. The author encourages clinical engineers to pursue all opportunities relating to the maintenance, management, and acquisition of medical technology, regardless of the size of the facility. One should not commit to responsibilities that one will not be able to successfully sustain. The traditional duties associated with the hospital clinical engineer involve equipment maintenance, equipment acquisition, consulting for renovation or new construction, and supervision of personnel (see Table 10-1). Equipment maintenance is associated with duties that include unscheduled corrective maintenance of medical equipment and scheduled preventive maintenance (PM) of medical equipment. The documentation of equipment maintenance and risk ranking (i.e., determining the frequency of preventive maintenance) is an extremely important duty relating to these activities.

Appendix 10-A (see Appendices) is a typical position description and list of performance evaluation criteria for a clinical engineer.

Equipment Acquisition

Equipment acquisition involves a planning phase, negotiating phase, and actual receipt of the equipment. Clinical engineers provide valuable technical expertise in the acquisition of medical equipment, which is acknowledged by hospital chief executive officers

Functional Economic Analysis for Defense Medical Logistics Standard Support, Office of the Assistant Secretary of Defense (Health Affairs), 1996.

Further Information

<http://www.tricare.osd.mil/> The Military Health System Web Site is the Official Web Presence of the Office of the Assistant Secretary of Defense (Health Affairs) and the TRICARE Management Activity, Skyline 5, Suite 810; 5111 Leesburg Pike; Falls Church, VA 22041-3206

Based on earlier work done in the Army's Southeast Regional Medical Command, which has been exploring regional operations for the past two years, the effort will require an investment in hardware, software, telecommunications, personnel, and office space, although marginal costs will decline as the number of sites increases.

Careers, Roles, and Responsibilities

Nicholas Cram

Texas A&M University
College Station, TX

(CEOs). Medical devices are considered capital budget items i.e., durable items. The purchase of medical equipment should coincide with the mission and vision statements of the organization and should take into consideration current and future needs of the organization.

Equipment Maintenance

Equipment maintenance involves all activities relating to providing an adequate level of service and limiting down time of medical devices in the facility. Traditionally, equipment maintenance is categorized as preventive maintenance and corrective maintenance.

Preventive maintenance (PM) is a scheduled event. PMs are scheduled according to the risk ranking of the particular medical device. Risk ranking is a unitless number derived from a formula that incorporates two factors: (1) relative maintenance frequency and (2) the effect on patient care if the device fails. Another duty associated with the responsibility of equipment maintenance is incoming inspection. All equipment entering a medical facility must be inspected prior to use. The inspection procedure should include performance and safety tests. The College of American Pathologists (CAP), which certifies clinical laboratory operations, has added computer safety testing to its list of device inspection requirements. It could be more cost-effective or a matter of necessity to contract the maintenance of a portion of the medical equipment in the facility's medical equipment inventory. In those instances when outsourcing is required, contract review will be a responsibility of the clinical engineering department. Clinical engineers review service contracts to ensure that PMs are being performed as stated in the contract and that associated corrective repairs are consistent with the work orders sent to the vendors providing service.

Fiscal Accountability

Clinical engineers with managerial responsibilities are accountable for expenditures related to medical equipment (capital equipment) and personnel (operating budget). As health care continues toward consumerism in the United States, fiscal accountability and technology management will become more of a focus for clinical engineers. Fiscal accountability falls into three broad categories: operating budgets; capital budgets; and project budgets. Each of these categories could be a responsibility of the clinical engineer. This will be discussed in detail in Section IV (Management).

Building and Renovation Projects

Clinical engineers have technical expertise and basic engineering skills; therefore, health care facilities rely on clinical engineers during renovation and building projects. It is not uncommon for the clinical engineer to be the only degreed engineer in the health care facility. Clinical engineers assist architects in the design and layout of special systems relating to medical devices during building and renovation projects. The specific section on blueprint drawings concerning nurse-call systems and other electronic or electromechanical devices is referred to as *special systems*. In many instances, clinical engineers may be

required to write a request for proposal (RFP), which outlines specifications for building projects. Appendix 10-B (see Appendices) is a sample RFP for a telemetry renovation.

State and Federal Regulatory Compliance

All state or federal regulations that relate to nurse-call requirements are the responsibility of the clinical engineer. State departments of health have health care facility requirements relating to radiation and laser safety. Clinical engineers are commonly assigned the role of laser-safety officer and training officer for radiation safety. This role involves conducting compliance surveys, distribution of safety-education materials, and ensuring that all required documentation is correct and current. Clinical engineers must have expertise in a broad range of regulatory areas to comply with national standards and codes such as the Safe Medical Devices Act (SMDA) and the National Electric Code (NEC) and regulations promulgated by such federal agencies as the Occupational Safety and Health Administration (OSHA), the National Fire Protection Agency (NFPA), and the Joint Commission on Accreditation of Health care Organizations (JCAHO) as well as local and state standards and codes.

Risk Management

The clinical engineering responsibilities for risk management can be categorized as quality-related or litigation-related. Documentation of all repairs and preventive maintenance as well as monitoring the scheduling and completion of these tasks are important roles in clinical engineering risk management. Clinical engineers are responsible for Food and Drug Administration (FDA) requirements relating to the SMDA. The clinical engineer may act as the chief investigator for medical device incidents that cause death, serious injury, or risk thereof, or he may coordinate investigation activities in accordance with SMDA requirements. Clinical engineers also may serve as expert witnesses in litigation involving medical device incidents.

Department Management—Vision and Growth

At the department level, activities are task-oriented. It is important that clinical engineers, as members of the management team, ensure that the focus of all activities reflect the larger picture of the mission and vision statements of the organization. All activities should be accomplished in an environment that fosters the core values of the system. Technology forecasting and an assessment of current and future needs are integral parts of department management. All successful department managers develop a department mission statement that correlates with the organization's mission and vision statements. An example of proactive technology forecasting and department vision is the role played by clinical engineers who are already anticipating the service opportunities provided by the Internet and telemedicine.

The primary role of the clinical engineer in departmental management is providing documentation for regulatory agencies and supervision of personnel. Although management styles vary according to personality and training, all successful CE management will have the qualities of consistency, respect, and ethics. Management of technical personnel requires an approach that differs from that of management of nontechnical personnel. Young, newly graduated clinical engineers will require closer supervision than will seasoned clinical engineers. In general, technical personnel should be allowed some independence in performing their tasks.

Clinical Engineering Responsibilities—Contemporary

Academic Affiliation/Teaching

Clinical engineering is a hands-on, application-oriented profession. Clinical engineers have a unique opportunity to bring their technical and clinical applications expertise into

the classroom in a vibrant and meaningful fashion. The answers to the many challenges that will face future clinical engineers and other health care professionals cannot be found in the textbook. Anecdotal accounts of actual clinical engineering experiences create a visual impression that makes the learning environment interesting for students as well as demonstrating a link between the knowledge of the classroom and the applications in the real world. Although teaching opportunities are somewhat limited, all clinical engineers are encouraged to seek out opportunities of traditional classroom instruction or mentoring a group of clinical engineering students in a structured clinical engineering hospital-internship program.

Applications Research and Design

The patient/device interface is the domain of the clinical engineer. Possibly no other role in clinical engineering can have such a dynamic impact on improving medical devices as that of applications engineering. Clinical engineers understand the clinical environment in which medical devices must function. With more complex devices being introduced into the health care arena, the technology can be overwhelming for physicians, nurses, and clinicians. Clinical engineers understand the medical device customer. Subtle human factors elements, which might be overlooked by other members of the design team, will be obvious to the clinical engineer. Clinical engineers find employment with medical device companies and in applications research for academic institutions.

Consulting

This is a relatively new area of opportunity for clinical engineers. Given the broad range of knowledge and various areas of expertise possessed by clinical engineers, it is not surprising that a niche market has developed for such talents. The range of consulting opportunities spans technology management and maintenance expertise to all of the responsibilities mentioned in this chapter. If a particular health care facility or medical device manufacturing company does not have the resources to accomplish a medical device-related task, whether technical or managerial, clinical engineers can provide a plethora of expertise to any challenge. The federal government also provides opportunities for clinical engineering consulting in its patent office and within the FDA medical device compliance sector.

Information Systems Support

Microprocessor components have become commonplace in electromedical devices. In addition to embedded microprocessor systems, several medical devices have signal-transmission and database interfaces. Several monitoring systems are actually specialized personal computers (PCs). This trend in medical device design provides opportunities for clinical engineers to provide technical expertise of clinical interfaces for information systems (IS).

In-Service Training

As medical devices become more complex, the need for facility user training becomes a necessity. Clinical engineers serve a role as clinical educators for physicians, nurses, and clinicians. Demonstrating the proper use and application of medical devices serves to improve the quality of care received by patients as well as providing more efficient use of medical devices and reducing the clinical staff's fear of technology. This is a role that will continue to expand and to provide future opportunities for clinical engineers.

Technical/Clinical Investigation

Clinical engineers may serve as the coordinator or primary investigator for clinical trials support of medical devices. A clinical trial involves research of leading-edge technology or new applications of proven technology. Clinical engineers will have responsibilities for selecting the team required for the clinical trial and coordinating all of the activities and required FDA documentation. The clinical trials area provides an opportunity for clinical engineers to act as independent consultants or to develop a niche area within their health care facility that could be a source of revenue. The management section of this handbook (Section IV) discusses the categories of revenue-producing and non-revenue-producing departments within a health care facility. The clinical engineering department is traditionally considered in the non-revenue-producing or cost-avoidance category. Any opportunity that allows the clinical engineering department to provide revenue is definitely a value-added service for the department and the facility as a whole.

Two roles associated with clinical trials are investigation drug exemption (IDE) compliance and participation in the institutional review board (IRB). An IDE is given to a medical device for use on a single patient when no alternative devices can provide alternative support. Obviously, these devices would be used in extreme patient-morbidity situations or situations when a proven technology is used in a different application from what the original patent intended. (This does not necessarily imply higher risk for the patient.) In each of the roles mentioned, clinical engineers can provide technical support and expertise that is not available through any other engineering discipline.

Technology Management

Technology management is perhaps the area that will provide the greatest opportunity of employment for clinical engineers. Clinical engineers have both the technical expertise and management tools required for successful management of technology. Technology is the primary driving force for change in health care. Management of technology will continue to be a necessary element of successful health care systems from both a financial and quality-of-care perspective. Technology management in health care involves the audit, planning, and acquisition of medical devices. It is not uncommon for medical device technology, capital, and operational budget items to encompass 35% of a health care system's total budget. Technology assessment has become an important tool for technology management. Technology assessment is a continual process of evaluating the technology within a health care facility with consideration of current and future needs. The technology assessment activity may derive information from primary sources such as manufacturers or in-house evaluations of medical devices being considered for purchase or from secondary sources such as the Internet, consulting firms, FDA sources, or newsletters. Considering the impact of this component, it is easy to recognize why the position of chief technology officer (CTO) has evolved. In some organizations, the CTO will have responsibilities for both medical device technology and information services technology. A more common scenario in larger facilities finds the CTO overseeing medical device technology management and the chief information officer (CIO) overseeing information technology management. The two positions have areas of overlapping responsibilities. Since software programs comprise an innate organ of several medical devices, the CTO and CIO must collaborate if achievement of improved technical quality and fiscal control is to be realized for the health care facility as a whole. A Master of Business Administration (MBA) degree specializing in technology management in addition to a Master of Science degree in biomedical or clinical engineering provides the ultimate resource for a candidate seeking a position as a CTO.

Clinical Engineering Responsibilities—Beyond Contemporary

Clinical engineering has begun—and will continue—to encompass the areas of telemedicine, virtual instrumentation, and web-enabled devices and systems.

Telemedicine

Telemedicine is an electronic-transmission medium that provides the exchange of medical information between at least two persons in geographically separate locations. Essentially, one can consider the telemedicine system as a transmission tube with either special monitoring devices or adapted medical devices connected to each end. Telemedicine activities require knowledge of telecommunications technology, networking technology, and medical device technology. The most intriguing development in telemedicine involves the ability to bring devices into the home for self-monitoring or monitoring by a professional staff. This concept has come to be known as *telehome-health*. With the large numbers of baby boomers approaching retirement age, telehome-health could see a dramatic increase in demand and acceptance as a medical standard. Several issues involving reimbursement need to be resolved before widespread use of telehome-health can be expected. Opportunities abound for clinical engineers in this arena. Several clinical engineers have already made an impact there (see Chapter 101).

Virtual Instrumentation

Virtual instrumentation has evolved in response to a need for more user-friendly and customized medical devices. A virtual instrument is a personal computer application that utilizes existing sensors, transducers or actuators to process the signals and present the information in a format desired by the user. This allows a system to be reconfigured as the demands of the medical equipment environment change while utilizing the same hardware and software (see Chapters 100 and 136).

Web-Enabled Devices and Systems

The Internet will change health care delivery. Exactly what those changes will be are difficult to determine at this time. The Internet has already influenced the manner in which patients—the customers—obtain health care information (see Chapter 73). Web-enabled devices that provide monitoring and signal-transmission capabilities with software interfaces residing on the Internet are a technical reality that may soon become standard practice. This new and modern arena will provide exciting opportunities for clinical engineers. As one might conclude from the sections pertaining to telemedicine, virtual instrumentation, and web-enabled systems, these modalities are intertwined and interdependent. This is the future of clinical engineering. Further insight into the future of clinical engineering can be found in Section XIII of this handbook.

A Day in the Life of a Clinical Engineer (CE)

The Rookie

Jean Smith recently graduated with a degree in biomedical engineering with an emphasis in clinical engineering. Finally, after a month of no response to some 50 resumes, Jean received an offer of employment in the Clinical Engineering Department at City Hospital. Today, Jean starts the orientation process. First, there is the issue of what to wear. (*What do clinical engineers wear, anyhow?*) Jean decides not to overdress and goes business-casual. Jean had completed a three-month, summer clinical engineering internship at the neighborhood hospital clinical engineering department. That summer, she found the passion needed to commit to the profession of clinical engineering. Today would be a different atmosphere. Physicians and nurses might ask questions about a myriad of topics. During Jean's internship, there was always a CE or biomedical equipment technician (BMET) nearby to provide an answer. "*What if I don't know the answers?*" Jean pondered with anxiety. As Jean entered the building, she was met by the director of clinical engineering and escorted to the conference room, where about 30 other new employees were seated. The anxiety was broken temporarily when several three-ring binders were shoved in Jean's general direction. The orientation speakers (there seemed to be a dozen) each introduced themselves and passed out more binders and papers to be signed.

Finally, the general orientation session was over. The director of clinical engineering met Jean at the door of the conference room and exchanged pleasantries, indicating that the entire department was excited about the prospect of adding a clinical engineer to the staff. There was something mentioned about PMs that needed to be finished by the end of the month, but Jean did not remember exactly in what context that related to any assignments that might be given that day. When Jean and the director arrived at the CE department, there seemed to be a flurry of activity. Each BMET and CE that passed Jean's way gave a greeting and a smile.

"I noticed from your resume that you've completed an internship," stated the director. "Yes," Jean replied, "at the neighborhood hospital in my hometown."

"Excellent," responded the director with a cheery tone.

"I guess we can skip training on the safety, defib, ESU, and NIBP analyzers?" added the director. Jean nodded in agreement but with some hesitation.

Her work area consisted of an electronic workbench inside an 8-foot, square cubicle. Jean was issued a basic electronic tool kit and became familiarized with the oscilloscope attached to a swing arm of the workbench. "*All seems somewhat familiar,*" Jean thought, realizing that the internship training was becoming invaluable. The director was off to a budget meeting and introduced Jean to the clinical engineering supervisor, Jan Jones. Jan had been with the CE department since graduation from engineering school 10 years ago. Jean spent the rest of the day with Jan being introduced to nurse managers and department directors, trying to keep mental notes on the hospital floor plan as well as all of the new names and faces. "*I'll never learn how to get around in this place,*" Jean thought.

That evening, on the drive home, Jean contemplated the first day on the job and realized that, at this point, worrying about not knowing the answers to questions that were never asked by the physicians and nurses was the least of concerns that day. Jean also marveled at the seemingly effortless manner in which Jan navigated the halls and elevators of the hospital and knew everyone's name. She was also impressed with the recognition Jan was given by each member of the hospital staff. "*Maybe I'll get there someday,*" Jean thought. "*Oh well, I survived Day One.*"

The Senior Professional

As Jan Jones sat in traffic en route to City Hospital, thoughts of the morning's agenda in the clinical engineering department began to surface. Jan was doing the mental to-do list, which had become a Monday-through-Friday ritual developed over the past 10 years. It seemed to make efficient use of time when the morning rush-hour traffic slowed to a crawl and made the all-too-common situation more tolerable. Two-thirds of the way down the mental to-do list, Jan remembered item 14: *Escort the rookie around the hospital and make him/her feel comfortable on the first day.* Jan's first day at City Hospital 10 years ago seemed a distant memory. Things at City in the CE department were a lot different now. More personnel responsibilities as the supervisor of the Clinical Engineering Department, the staff had doubled in CE, more complex equipment, and a more visible presence among the other hospital co-workers due to the numerous planning meetings involving equipment acquisition, building and renovation projects, and the research partnership with the biomedical engineering department at City University. Traffic was moving again, and Jan's car seemed to find its own way into the now familiar parking stall at City Hospital. "*OK, morning ritual; grapefruit juice (Jan was trying to cut out caffeine), check the work orders, anybody call in sick today?*" The director had already left with the rookie for morning orientation. "*Glad I don't have to go through that process again,*" Jan thought. The rookie would be coming back for a tour of the department and the facility after lunch. Jan decided to work on the capital budget planning and review the month's operational expenses. Before she could start, a BMET had a question about a power supply repair for the monitor in the intensive care unit. Jan asked the obvious, but necessary, question: "Have you checked all the fuses and power from the outlet?" The BMET gave a nod about the fuses, but the outlet had not been checked. Jan was about to return to the budget reports when the process was interrupted by a phone call. It was the nurse manager (NM) for the neonatal intensive care unit (NICU). The NM's voice had an urgency and anxiety that was common to most NM phone calls. "Have the fetal monitors been tested recently?" the NM asked. Jan pulled up some information in the computerized maintenance management system.

"Yes, just last month," Jan replied.

"Well, I've got ECG artifact on three monitors, and these are all critical infants," the NM roared.

"OK, we'll check it out right away," Jan responded calmly. She approached the BMET with the power supply problem. "Can you swing by the NICU and check out the monitors?" Jan asked. "Take some new ECG leads with you. We've got an artifact problem up

there.” Jan stated matter-of-factly. OK, back to the budget reports. After a few more phone calls Jan was able to make some progress on the presentation for tomorrow’s budget meeting. “I’ve got enough time to grab a bite to eat before the rookie is finished with orientation,” Jan thought. Now it was the dilemma of cafeteria food or running across the street to the deli. She decided to take a chance on the cafeteria. “*Hey, not bad,*” Jan thought as the new food-court style cafeteria was surveyed. “*Not like the old days,*” she mused. As she finished lunch and headed back to the clinical engineering department the director of cardioumonary services rushed by to ask a question. The director quizzed Jan on the status of replacing some of the older ventilators. Jan assured the director that it was on the agenda for the next morning’s budget meeting. She made it to the back to the clinical engineering department shortly after the director had arriving with the rookie. “Jean meet Jan, our CE supervisor,” the director stated as the traditional handshake process began. “Jan will be your mentor for the first few months until you feel comfortable with your roles and assignments,” the director stated. Jan and Jean exchanged some personal background information and then started off on a tour of the hospital. Jan identified each clinical area as they passed them by, introducing Jean to different members of the staff as they became available. Jan noticed the wide-eyed look on Jean’s face about a third of the way through the tour. “Don’t worry” Jan said, “You’ll get used to it. All this will become second nature after your first month.” Jean nodded but without any reassurance. Back in the CE department, Jan introduced Jean to fellow CE coworkers. It wasn’t exactly a typical day for Jan—a little slower-paced than usual. Tomorrow, Jan could catch up on the dozen e-mails that went unattended due to the rookie’s tour. “*Jean will find that niche and become comfortable with the CE environment.*” Jan thought. The curiosity and enthusiasm that Jean displayed were key indicators that she had chosen a career field that would fill a personal passion required in health care. “*I’ll wait another week before I start*

assigning Jean any PMs,” Jan decided. “*No reason to tarnish the academic idealism until the appreciation for our purpose sets in.*”

Clinical Engineering at the Bedside

Saul Miodownik

Director, Clinical Engineering
 Memorial Sloan-Kettering Cancer Center
 New York, NY

For the past several years, the practice of clinical engineering has shifted from the patient’s bedside to the office suite and meeting room. Fundamental components of a clinical engineering department’s activities should include bedside consultation in the midst of clinical procedures for the purpose of problem solving, interpretation of medical information, and clinical staff education.

The field of clinical engineering has undergone several evolutionary cycles since it emerged as a profession in the 1970s. In many instances, our *raison d’être* derived from fears of imperceptible, but potentially lethal, 60-Hz leakage currents that might have been taking an untold annual toll in lost patient lives. The reports of dangerous leakage currents in the medical literature were anecdotal in nature and often followed an adverse clinical manifestation that was associated with the use of electrical equipment. A careful engineering investigation of medical equipment and its use in the clinical environment eventually revealed the true nature and scope of this hazard. Although the perceived liability failed to materialize, many clinical engineering jobs and even entire departments owe their existence to this scare. It was inevitable that many clinical engineers were thus directed to the task of tracking medical equipment and their associated leakage currents as their primary function. As the issue of leakage current hazard was gradually put into a more reasoned perspective, clinical engineering departments directed their efforts toward a broader spectrum of medical technology support, management and acquisition. Along with this, systems and policies were established to assure timely inspection intervals, repairs, and compliance with required standards. With the widespread use of computerized systems for medical equipment management, a cornucopia of data became easily available to enable a host of departmental management tools such as performance appraisal, quality assurance (QA), and benchmark comparisons.

Clinical engineering presence in the scope of health care delivery continues to be ubiquitous. Addressing issues of safety, technology acquisition, scheduled and unscheduled maintenance, incoming inspection, regulatory compliance, quality assurance, and facilities management consume larger proportions of available time.

Nevertheless, it seems that the ultimate recipient of medical technology, the patient, has become an increasingly remote component in the delivery of clinical engineering services. Clinical and biomedical engineers have always been in the unique position of acting as a bridge between the medical and technical environments. Theoretically, knowledge in both fields would allow the safer and more efficacious application of a diverse techno-

logical armamentarium over a broad spectrum of clinical situations. However, the current trend in clinical engineering appears to be drifting ever farther from its clinical source.

One component of this trend is the “queasy factor.” The raw clinical environment is decidedly messy. Many people would choose to avoid the presence of blood, body fluids, secretions, smells and human beings in various states of distress, disassembly, and mortal danger are places. That the nursing and physician communities encounter these as matters of course. Clinical and biomedical engineers and technicians can often selectively avoid the most distressing aspects of the clinical environment.

I am reminded of a poster session I once presented at a meeting of the Association for the Advancement of Medical Instrumentation (AAMI). Meeting attendants would stroll down the poster aisle until a topic of interest caught their eye. My poster was about the development of an extracorporeal gastric-assist device that would transfer a patient’s stomach contents into the jejunum, thus bypassing an obstruction or region of paralysis. The visual materials were graphic, showing the gastric and jejunal stomae, the interconnection of the assist device to various tubes entering and leaving the patient’s body, and views of stomach contents and bile being transferred by the pumping device. This device was a productive collaboration between the departments of gastroenterology and clinical engineering and required the cooperation of several patients. It directly and immediately improved the patients’ quality of life. The clinical engineering department installed these bypass pumps on these patients and consulted with them regarding its care. A few attendees were genuinely interested and stopped to engage in lively discussions. Most, however, accelerated the pace of their stroll when the nature of the poster became apparent. I walked down the poster aisle to see that other topics being presented included such sterile matters as bench testing of mechanical thermostats, various simulators and biomedical test equipment, medical equipment management programs, and a few *in vitro* studies on biocompatible materials. If my poster was the proportional representation of clinical engineering in the clinical environment, then little was being done in this arena.

When clinical engineers actively participate at the bedside, there is the potential for great benefit for the patient, the medical staff, and for the clinical engineering community. The insight, perspective, and problem-solving capabilities that the clinical engineer brings to the scene are often different from those of other members of the medical staff. Once this type of expertise is developed and recognized, it will be called upon with increasing frequency and beneficial results.

Case Studies of CE at the Bedside

Following are several examples of clinical engineering at the bedside.

Case 1: Chin Up! The Lesion Generator Really Does Work

During a computed tomography (CT) guided procedure involving nerve ablation to address chronic facial pain, the clinical engineering department was called to go to interventional radiology to determine why the neural lesion generator was developing insufficient heat. The neurosurgeon demonstrated the temperature rise as measured by the needle probe depositing the energy at the lesion site. At first, the temperature rose, then reached a plateau. After a few seconds, it dropped. Increasing the output setting of the lesion generator did not improve this situation. Clinical engineers verified the radiofrequency (RF) output of the generator and found it to be nominal. After pondering a while, the clinical engineers entered the CT area and asked to be shown the site of the return electrode. A drape was pulled off of the sedated patient's head where, to the horror of the engineers, an 18-gauge needle with the return wire attached was seen protruding from the patient's chin. There was a significant area of desiccated tissue surrounding this needle. I quickly obtained an electrosurgical return electrode and modified it to be used with lesion generator. The procedure was then able to proceed normally. The neurosurgeon was delighted that the procedure could be completed. In the absence of our intervention, the patient otherwise might have left with even greater pain than before. We explained to the medical staff the nature of electrosurgical return currents and the need to distribute the current density over a wide area. In this instance, the heating at the needle return site dried out the tissue and decreased the overall current produced by the lesion generator and, consequently, the energy available at the desired site for heating. The surgeon was grateful to learn this information (he had been performing this procedure for years with no apparent adverse outcome until now), the patient was able to benefit from the relief of his chronic pain, and the clinical engineering section demonstrated its understanding and quick thinking in remedying the situation.

Case 2: Argon Beam Coagulator Fails under Pressure

Following the introduction of argon beam coagulation (ABC) devices, it was brought to our attention that, under certain conditions, the argon "beam" failed to ignite and to properly deposit the electrosurgical energy at the desired site. The operating room (OR) technical people were constantly swapping out generators in hopes that one unit might perform better than another. All ABC devices performed flawlessly during testing in our clinical engineering laboratory. We went to the OR to observe various ABC surgeries to determine whether a pattern that would help us determine the problem could be identified. It became apparent that problems arose when the ABC handle was being used deep in a body cavity. At first, ignition proceeded normally, but after a few moments the argon beam became intermittent and sometimes ceased completely. Proper operation of the ABC was verified with our electrosurgical unit (ESU) tester, and the argon beam was successfully generated on an open field. Entering the body cavity quickly reproduced the problem. I suggested that perhaps a small amount of back pressure was being developed in the deep cavity that could interfere with directed flow of the ABC. A suction catheter was placed a few centimeters above the ABC handpiece, and its flow was adjusted to approximate that of the argon flow of the ABC unit. That did the trick. Surgery proceeded normally.

Case 3: Clenched Jaw Signals Swamp EEG

During a rather complex neurosurgical procedure to remove an egg-sized tumor from the right side of a patient's brain, a problem was encountered with an electroencephalograph (EEG) data-acquisition system. Following a craniotomy, this device is used to map the functional regions on the surface of the brain to the patient's various motor and sensory areas. In order to do this, the patient must remain conscious. The EEG operator provides a sequence of electrical, optical, acoustic, and mechanical stimuli in order to identify a surgical approach to the tumor that will cause the least amount of damage to the patient's neurological function. In addition to the EEG device, other medical devices were involved, including an ultrasound imaging system, radiofrequency position generator, bipolar coagulator, ultrasonic tissue ablation, stimulators, and irrigators. The EEG operator, who was quite experienced and had done dozens of similar procedures, was unable to record acceptable signals because of an intermittent high-frequency noise on all eight EEG channels. It was initially thought that this noise originated from one of the many other instruments in the room, but this could not be confirmed. Filtering of the signals did not work, as the noise appeared to be in the same frequency domain as the EEG signals. To complicate matters, the patient was able to hear fragments of the conversation between the surgeon and the EEG operator discussing the reason for the delay in the surgery. He readily expressed his anxiety.

At that point, we were called to assist. Every instrument, in turn, had been turned off to determine whether it was the cause of the EEG interference. Indeed, after a few moments of observation, the extraneous "noise" would almost entirely disappear and then, suddenly, completely mask the desired EEG signal.

A closer look at the electrode site was made. The common reference electrode was positioned in the scalp fascia near the craniotomy. The location of the reference electrode is usually not an issue. In this instance, however, the needle electrode appeared to have penetrated some muscle tissue as well. We observed that when the patient was questioned or stimulated, the noise would reappear and sometimes subside as well. We hypothesized that the noise was an electromyographic (EMG) signal caused by tension in the scalp musculature when the patient was aroused or when he felt anxious. A reference electrode site that avoided muscle tissue was carefully chosen. The problem was resolved.

Case 4: Air Today; Gone Tomorrow?

A patient in the intensive care unit (ICU) required the use of a transthoracic pacer. A defibrillator/pacer, normally kept in the unit, was used. Disposable pacing electrodes, which can double as defibrillator paddles, were placed in the classical transthoracic posi-

tion (over the heart and on the patient's back). However, the pacer would not capture. The pacing current was increased but would still not capture. The defibrillator-pacemaker was changed to a second unit with no better results. Clinical Engineering was called in to assess the "failure" of both pacers as the staff began preparing the patient for the insertion of a temporary transvenous pacing catheter. Our records indicated that both units had been recently inspected and were working properly. A quick test in the ICU confirmed this. I returned to the patient's cubicle and looked around. I noticed that the patient had a chest-drainage tube in place. I spoke to the medical staff who informed me that the patient was being treated for a pneumothorax that had occurred a short while before the pacer was required. The pneumothorax would allow air to enter the chest cavity. If some of this air had been present between the heart and chest wall, where the anterior pacing electrode was placed, it might account for the lack of capture by the transthoracic pacer. Even at high pacing currents, the insulating air prevented enough current from crossing the myocardium and causing capture. The increasing pacing current found a route around the chest wall with very of the current passing through the heart. The electrodes were repositioned to sites that reliably allowed the pacer to capture the patient's heartbeat. This clinical engineering intervention might have averted a catastrophe had the need for defibrillation arisen. The catheter insertion in this patient in the midst of an ongoing episode of bradycardia might have triggered arrhythmias or even ventricular fibrillation. If an attempt had been made to defibrillate the patient, the same air pocket over the heart may also have prevented successful defibrillation.

Case 5: Pump Puts the Squeeze on Plastic Tube, Sending It into V-Tach

The ICU cubicle can become an extremely complex environment in a short period of time. Within 24 hours, patients who start with simple monitoring of ECG, noninvasive blood pressure, and pulse oximetry can require such things as a mechanical ventilator, invasive arterial and venous access, and multiple infusion devices. As the patient's condition deteriorates, additional interventions, therapies, and medications are used.

We were called to the bedside of a very sick patient who apparently had gone into what appeared to be a ventricular tachycardia (V-tach). Two attempts at cardioversion and the administration of potent cardioactive drugs appeared to have been ineffective. To further complicate matters, a 12-lead ECG taken independently of the ECG monitor did not support the observation of V-tach. A view of the central station monitor seemed to confirm the presence of V-tach on the ECG trace. Surprisingly, the invasive pressure and pulse oximeter tracing indicated a relatively normal set of cardiogenic traces, inconsistent with the ECG. Further analysis of the situation was made all the more difficult by the infection-control precautions posted on the door of the patient's cubicle. I looked into the room and was confronted with what appeared to be most of the ICU's portable equipment and about half of its staff. In addition to the normal, full-function physiologic monitoring system and the usual three or four infusion pumps, two extra pumps had been rolled in to administer cardioactive drugs; the defibrillator-pacer was standing by to convert the V-tach rhythm; the 12-lead interpretive ECG machine was in place; and, at the foot of the patient's bed, a portable continuous arteriovenous hemofiltration/dialysis unit (CAVHD) was in use. Except for the defibrillator and the additional IV pumps, the entire assembly had been in use for a number of days with no consequence. The only other piece of information was that the V-tach had begun about 45 minutes earlier following the patient being cleaned and his ECG electrodes changed. The diagnosis of V-tach was identified by the physicians and verified by the arrhythmia computer within the patient monitor.

My line of sight placed the CAVHD alongside the monitor. Without much thought, I alternately scanned back and forth between the various roller pumps on the CAVHD unit and the ECG trace on the monitor. The blood pump was rotating at a rate that seemed to correlate with the ECG trace. Proceeding on a very good hunch based on experience, I asked that the blood pump be stopped. It slowed to a stop after a couple of seconds. When it did, the patient's ECG trace also returned to "normal," to the amazement of the nursing staff and residents and to the chagrin of the attending physician who ordered the cardioversion. What had happened?

There is a published, but little-known, phenomenon that relates to the piezoelectric characteristic of polyvinyl chloride (PVC) plastic commonly used in medical tubing. I had encountered this early in my clinical engineering experience, and a medical journal at a later date published a letter to the editor that I had sent regarding this effect on ECG tracings. PVC tubing will generate a small, but measurable, voltage when it is rapidly squeezed or released. Voltage can propagate along conductive fluid contained within the tubing. The amplitude of the voltage so propagated is dependent on a host of factors (e.g., tubing age, durometer, temperature, composition, and pressure change) The voltage that can arise on the patient surface depends on the tubing penetration site on several factors including the patient, electrode impedance, and intrinsic ECG voltage. Depending on the pinch rate and the other factors mentioned, this piezoelectric effect can mimic or mask a wide range of ECG anomalies, from atrial fibrillation to V-tach. Our patient was somewhat obese and had a fair degree of edema. His intrinsic ECG voltage was < 0.5 mV in lead II. The ECG electrodes were replaced after he was cleaned, with no particular consideration given to skin prep or placement. The entry point of the CAVHD tubing was within 10 cm of the LA ECG electrode and was precisely in line with the RA-LL electrodes for lead II. The roller pump rate for the patient's blood produced one compression and one release of the tubing within the roller guide about every 0.3 seconds. The triangular voltage waveform generated by the pump and seen on lead II of the monitor was in the order of 1.5 mV, virtually masking the patient's own ECG. When skin resistance is high and ECG voltage is low, there is a greater susceptibility to external interference.

When the ECG was taken with the 12-lead automated machine, the electrodes, which were approximately 1-inch square, were placed on the patient's limbs significantly removed from the entry point of the CAVHD tubing. In fact, the piezoelectric signal could be regarded as common mode interference considering its relative distance from any but the V-lead chest electrodes. This would allow the high common mode rejection ratio (CMRR) of the ECG amplifier to reject this interference. The large, square area of the electrodes used by the 12-lead ECG machine also assured a lower impedance connection to the patient than was possible with the monitoring electrodes. This situation would also

tend to reduce the apparent amplitude of the interfering signal. After much judicious skin prep and repositioning of the ECG electrode, we were able to safely monitor the patient.

Conclusions

The health care technology managed by clinical engineering departments should not be viewed merely as entries in a database and subject to an occasional periodic maintenance and repair. Although procedures exist to verify a medical device's proper operation within a set of technical specifications, there is a clinical context to their daily use that must be intimately understood.

In all of the aforementioned cases, the following assumption was made: "Something is wrong with the machine, call Clinical Engineering." However, in each case, the hardware performed flawlessly. A solution to the problem required a comprehensive understanding of the immediate clinical situation, anatomy and physiology, the physics of the

instruments in use, and knowledge of fundamental instrumentation characteristics. The practice of clinical engineering at the patient bedside requires the integration of this knowledge, experience, and quick thinking on one's feet.

Structuring these concepts to assure clinical engineering involvement at the bedside is not difficult. At all staffing levels, from the BMET to the section's head it is possible to encourage and participate in this form of activity. Following courses in anatomy and physiology, a basic requirement of a clinical engineer's education and experience should include a familiarity with the kind of activities that occur at the patient's bedside. Ideally, this can be learned or experienced by observation in the intensive care unit, operating room, or emergency room. Following the medical staff on rounds is an effective method of observation. Consistent exposure to the multitude of procedures, terminology, pace of activity, and use of equipment in these areas is a mandatory prerequisite for those who wish to apply their abilities at the bedside. An intimate understanding of principles of the instrumentation used and the clinical situation can often lead to solutions to otherwise intractable problems.

12

The Clinical Engineer as Consultant

J. Sam Miller

Clinical Engineering Consultant
Buffalo, NY

Clinical engineers as consultants play an important role in the health care industry. All practicing clinical engineers serve in some capacity as consultants because they have unique training, knowledge, and expertise that are of value to those in ancillary health care fields. Many of the tasks routinely performed by a clinical engineer in a hospital in support of administration, physicians, nurses, and clinics are actually consulting tasks. This chapter, however, is devoted to consulting in the sense of rendering engineering services to clients for a fee. The topic is presented here with an overview of the present clinical engineering consulting field and answers the dual question of "Who is doing what for whom, and how?" Credentials and qualifications are briefly presented, followed by practical business considerations for both the full-time and part-time independent consultant.

General Overview

Who Are the Consultants?

Clinical engineering consultants are those clinical engineers (CEs) who have found that their level of experience and expertise places them in demand for technical advice in the field of medical equipment. Some have specialty niches, but the majority simply have a broad working knowledge of the use of clinical equipment and management of technology.

There are probably fewer than 100 clinical engineers serving as consultants at the present time, but there is no central list or directory available to confirm that figure. The *Membership Directory* of the Association for the Advancement of Medical Instrumentation (AAMI) lists 5,587 persons as members, with 151 of those listed with the job title of *Consultant*. However, of those, only 20 have a Ph.D., M.S., or certification in clinical engineering. Most of the others listed are consulting as accountants or marketing managers, or with a technical specialty such as sterilization or prostheses. AAMI also offers a *Directory of Medical Technology Consultants* (for a fee to be listed) that currently lists 12 consultants (2002); however, only three of those offer general CE services. The American College of Clinical Engineering (ACCE) membership directory (2003) lists over 150 CEs but does not designate consulting involvement. (See Chapter 130.)

Further insight into who the consultants are can be obtained by searching the web using key words such as *clinical engineering consulting*. There are only a few consultants who currently have web sites to promote their business and to list their qualifications; e.g., <http://biomedeng.com> and <http://www.hrbiomedical.com/page4.htm>. This form of marketing consulting services will grow in the future.

How Do They Consult?

The better-known consultants in this field practice on a full-time basis, some as members of consulting firms or groups and some as self-employed independent consultants. There are also well-known consultants who practice on a part-time basis because they are

otherwise employed full-time by hospitals, universities, or industry. In this latter case, they usually have an agreement with their employers that allows them to do some consulting on a noninterfering basis. Conflict-of-interest agreements are recommended in these cases to protect both parties; however this usually places limits on the types of consulting projects that can be undertaken.

Who Hires Them to Do What?

There are many different activities in health care that have a need for independent clinical engineering consulting, usually to give technical advice, solve problems, or provide specialty information. The following is a partial list of these activities:

- Assisting the in-house CE whenever expert advice or corroboration is needed
- Assisting hospital administration whenever expert technical advice is needed
- Assisting physicians in new technology or research areas
- Assisting medical equipment entrepreneurs, manufacturers, or vendors with the introduction of new technology (or upgrading old technology)
- Assisting the legal field in product liability/malpractice cases involving medical equipment
- Assisting with the education of medical or engineering professionals
- Assisting hospitals in other countries with the introduction of new programs or technology

Consultants for the first two roles above can be CEs with a particular expertise in a problem area, but they also could be non-CE consultants in a specialty field adjunct to CE, such as emergency power systems, environmental engineering, radiation safety, or telecommunications. Most practicing in-house CEs are naturally reluctant to retain an outside consultant, but if they are able to do so, they find that their own image as an expert is bolstered and that doing so exhibits good management skills.

However, in-house CEs may find that they themselves can serve others as experts in any of the areas described above. Although most in-house CEs do not seek out these consulting opportunities, they are often recruited for such tasks based on their relative experience level and reputation in the community. The legal field often needs to use a CE consultant for technical advice and as an expert witness (see Chapter 13) in malpractice cases involving use or misuse of medical equipment or for product liability cases. CEs who work in local hospitals are commonly used in these instances.

Hospital administrators, particularly those from smaller facilities, can use independent CE advice in reviewing their clinical engineering support services and activities. In some cases, such assistance is requested by the in-house clinical engineering to give credibility to its operations. Consulting for hospitals to advise on programs to ensure compliance with the recommendations of the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) or with state health department requirements. Consultants also assist administrators in the development of technology management programs and policies.

Physicians often need technical assistance with new equipment purchases, grant writing, or research protocols. Human research committees or institutional review boards (IRB) in teaching hospitals and universities can benefit by adding an independent clinical engineer as a consultant to the group. Physicians or other health professionals in state and federal agencies also use CE consultants to review rule making or new medical device applications, or to assist with audits.

Manufacturers of medical equipment—especially smaller manufacturers—often do not have engineers with practical clinical experience on their staff, and they need help in bringing new products to market. Practicing CEs are well-suited to assist with functional engineering design details, with premarket clinical trials, with U.S. Food and Drug Administration regulations (see Chapter 126), and with standards promulgated by organizations such as the American National Standards Institute (ANSI), the National Fire Protection Association (NFPA), and AAMI. (See Chapter 118.) A related consulting area involves technical reviews for venture capital firms of financial proposals from entrepreneurs who need funds to introduce new technology.

To support the field of education, CEs who consult often find themselves invited to participate in the training of students in the health professions, which sometimes leads to part-time faculty positions. Assisting with grant writing and instrumentation used for medical-research projects are other typical university needs that can be filled as a consulting service.

Finally, assisting health care facilities in developing counties with the general area of technology management is an important need at the present time. There are programs funded by the U.S. government that will retain consultants for assistance, but there is also a need for volunteer CE efforts to assist in training programs in these countries. The ACCE routinely conducts Advanced Clinical Engineering Workshops (see Chapter 70) several times a year using a volunteer faculty of CE experts from the consultant ranks.

Qualifications and Credentials

One of the quirks of the consulting field in general is that there are no set standards for being a consultant. CEs can print up business cards and can call themselves consultants. In the field of clinical engineering, however, there are some credentials that help to establish credibility:

- an advanced engineering degree, preferably a Ph.D., from a well-known university
- a Professional Engineering License or certification as a clinical engineer
- membership in professional scientific, technical and engineering societies; e.g., ACCE, AAMI, the Institute of Electrical and Electronics Engineers (IEEE), the American Society of Hospital Engineering (ASHE), the National Fire Protection Association (NFPA), and the American Society of Mechanical Engineering (ASME)
- membership in local professional societies or organizations (e.g., the Chamber of Commerce or health care, engineering, or consulting groups)

There are also certain factors that help to qualify a person as an expert and that are related to years of experience in the field. In a local community, people become known over time and develop a reputation based on the quality of their work. Speaking at local health care society meetings on new technology advances or innovative projects that one has been involved with is an excellent way to enhance one's reputation locally. Referrals from colleagues in related health care fields then often lead to new consulting opportunities.

In the national and international arena, professionals become known as experts over time primarily by their publications and participation in national or international technical meetings. By voluntarily participating in the work and activities of a professional society, a person becomes known by their peers and develops a reputation. In the field of clinical engineering consulting, the most authoritative qualification as an expert is by recognition from peers.

Business Aspects of Independent and Part-Time Consulting

This section considers the factors that are important for a practicing clinical engineer to look into when deciding to offer consulting services on a part-time, or moonlighting, basis. Although most practicing clinical engineers are employed by health care providers, these same considerations will apply to those CEs who work for industry, universities, or the government. Part-time consulting usually begins as follows:

As CEs become established in their work settings, they are soon recognized as technical experts by the physicians, nurses, administrators, and other nonengineering professionals with whom they interact in their day-to-day activities. And they are expected to provide expert advice, as needed, to these coworkers as part of their job responsibilities. However, ethical considerations arise when someone who is not a coworker (e.g., an attending physician or a university researcher) asks the CE for some free advice about some technical problem that they are facing. Most of the time, the CE can provide the needed information in a few minutes of conversation, and nothing much is thought about it from a business-ethics standpoint. But what if the physician, for example, needs to have an interface designed and built so that he can use his PC to view ultrasound images, and he offers to pay the CE for the work?

Another common situation occurs when an in-house CE is contacted by an attorney who works for the law firm used by the CE's employer, and the attorney needs some assistance (for a fee) about a case that does not even involve the CE's employer. If the CE is properly established as a part-time consultant, with their employer's permission, these kinds of events can become win-win-win situations. The CE wins with a bit more income and prestige; the CE's client wins because the client found help without feeling that it was an imposition on the CE's employer; and the CE's employer wins because the employer

has become better-known as an organization with recognized experts on its staff and also as a good neighbor to the business community.

How Can Such a Part-Time Service be Arranged?

For the CE, the first consideration should be whether or not the extra work can be done without serious negative impact on the employer, the family, or other personal interests. If the CE is already routinely putting in sixty- to eighty-hour workweeks or attending graduate school in the evenings, then the prospect would be ill-advised. But if the CE is willing to put in the extra time and to give up some holiday and vacation time to work on a project for a client, and if the CE's employer allows some flexibility with work hours, then establishing a part-time consulting service is a definite possibility.

One key to avoiding problems with the employer is to have a written agreement, even as simple as a memo or letter, signed by both the CE and the CE's administrative supervisor, detailing the ground rules for the use of the CE's time for the outside work. The agreement should also detail the CE's use of the employer's resources (e.g., computers, work areas, test equipment, parts, and libraries). In addition, a formal conflict-of-interest statement should be generated by the CE and accepted by the employer, calling out the specific nature of the CE's consulting work and clients. For example, the employer may wish to exclude competitors or providers of goods and services.

Basic Business Elements to Consider

Part-time consulting activities should not impact your normal duties to your employer and should remain as separate as possible. One way to achieve this is with a home office, a place to work independently from the nine-to-five job. But if this option is not practical, then it will be important to keep good written time records of all your consulting activities.

Your initial clients probably will be physicians, lawyers, or manufacturers whom you know from your involvement with them at work. To avoid any conflict of interest, the consulting work should be limited to tasks that are clearly separate from any dealings that your client may have with your employer. It also would be advisable not to accept any consulting work from manufacturers who are competing for business with your employer.

Promoting Your Services

Retaining your first client is usually not an easy task, unless they come to you for help with a specific problem. One recommendation for getting started would be to make a list of potential clients and the tasks that you might perform for them. Then select the one that you would be most comfortable doing work for, and ask that one to have lunch with you to discuss a business idea. Explain that you are now available for consulting work, and let it be known how you could be of assistance. Have an outline of your ideas and an up-to-date copy of your curriculum vitae (CV).

Before you approach the next potential client, do a self-critique of that first meeting to see what you should do next time to improve your approach. It may take only two or three contacts like that to win your first consulting job, and then your efforts should go toward performing that work in an expert manner. Agree to your fee at the same time that the scope of the task is defined, and do 'not underprice your professional fee.

Details to Consider

After one or two successful consulting assignments, you should know whether this part-time, self-employed approach meets your needs and whether you want to continue. If so, here are some ideas to make your efforts more productive:

- Set up a home office and a computer to keep track of contacts, billable and nonbillable time, accounting (including taxes), and to provide Internet access for e-mail and web information searches.
- Have stationery and business cards printed, and consider a simple brochure listing your particular areas of expertise.
- Sharpen your public-speaking skills by way of seminars or participation in the local Toastmasters organization.
- Consider joining local professional or fraternal organizations and attend meetings.
- List yourself as a consultant in any directories that are publicly available. Search the Internet for opportunities to promote your services (e.g., <http://www.a2moonlighter.com>).
- As business increases, ask an accountant for assistance with taxes (you might have to file quarterly estimated-tax payments), and consider errors-and-omissions insurance.

Business Aspects of Independent Full-Time Consulting

This section expands on the part-time business considerations, adding items that are important for starting and operating a full-time clinical engineering consulting service.

Business Basics

Every business should start by developing a written business plan. (See Chapter 140.) This may seem at first to be unnecessary because most engineers think that they know what they want to do and how to get there without needing to write it down as a plan. However, most failed businesses identify the lack of a formal business plan as a major reason for failure. Developing a written business plan forces one to systematically consider details that are otherwise overlooked and provides a practical roadmap to get you where you want to be. A few hours at a public library will provide one with many resources (e.g., Cuppett, 1966) for developing a plan for a relatively small venture such as a consulting

service. This plan, if reviewed and updated every 6 months, can become a great working tool for measuring progress and continuously improving quality.

Key Elements of the Plan

- First, clearly state the business philosophy (basic beliefs and important values) and mission (the primary focus of the business).
- Define short- and long-term goals with measurable objectives.
- Develop a strategic plan defining the following elements: present status, marketing plan, operations plan, administrative plan, financial plan, timeline for the above, and tactics.

Development of this strategic plan and tactics should include analysis of strengths, weaknesses, opportunities, threats, and conflicts in a systematic and realistic manner. Marketing should include a list of the needs that your various types of clients have, and which of those needs match your abilities. Operations should detail office space, equipment, and support needs, both currently and for future growth. Financial and administrative details go hand in hand. One needs to determine what type of business one has (e.g., "doing business as" (DBA), incorporated (Inc.), limited liability corporation (LLC), and sole proprietorship); the structure of the business (e.g., officers, owners, survivors); start-up funds and contingency funds, fees, accounting system, tax status and tax filing requirements. Finally, the plan should be projected to cover 5 years. Historically, most new consulting businesses require that length of time to become stable and profitable.

Business Resources

Starting a new business, especially if it is a one-person operation, has the potential to be very rewarding personally and financially. But there are many pitfalls to avoid. There are no bosses, work companions, or secretaries to help keep you going in the right direction, so it is important to develop a support-and-resource network. Many localities have professional consultant membership organizations that meet regularly for the purpose of improving their business skills, sharing problems and leads, networking, and socializing. Although their members generally are from business fields that are not related to clinical engineering, most problems that they face and issues that they address are generic to any

consulting field. And the meetings are often a forum for presenting plans or ideas for group critique. This path would be an excellent way to obtain peer review of a new business plan or marketing approach. Check the newspaper listings for calendars of local business meetings to locate such a group, as they generally are not listed in the telephone directory. If there is not a group that is specific to consultants in your locality, there are other business-related, self-help membership groups that operate in a similar manner, such as Toastmasters, Rotary, and the Chamber of Commerce.

Spend some time studying the general field of consulting services. Again, the public library has considerable resources for this kind of information (e.g., Cimas, 1999; Holtz, 1989). It is also important to maintain professional health care and engineering ties. Organizations such as ASHE, IEEE, and ASME usually have local chapters that meet regularly. Local and/or state health care providers and clinical engineering groups have membership meetings. (See Chapters 131 and 132.) The information and exposure gained by networking at such meetings is invaluable to the new consultant.

Summary

The topic of consulting is of interest to every clinical engineer because it holds the promise of exciting and rewarding work, reasonable compensation, and flexible work hours. The successful consultants, however, are those with many years of experience in a clinical setting, excellent credentials, and, most importantly, a reputation as an expert.

The Clinical Engineer as Investigator and Expert Witness

Jerome T. Anderson

Principal, Biomedical Consulting Services
San Clemente, CA

With the expanding use of technology, the volume of medical devices and capital equipment has greatly increased over the years. This has been accompanied by an increase in injuries and untoward outcomes attributed to medical devices and equipment (see Chapter 84). The trend came to the forefront with Congress's passage of the Safe Medical Devices Act (SMDA) of 1990 (see Chapter 126). Prior to this act, patient injuries were investigated internally for purposes of defending a claim or preparing for potential litigation. While manufacturers were required to investigate injuries reported to them prior to passage of the law, the inclusion of health care facilities in the requirement greatly increased the requirement for investigation of injuries or death thought to be related to the failure or misuse of a medical device.

The call for investigation of medical device-related injuries has grown stronger through the inclusion of the investigative requirements in revisions of the standards of the Joint Commission on Accreditation of Healthcare Organizations and the recent movement in the U.S. to reduce medical errors that result in harm to patients (see Chapter 55).

The clinical engineer is a natural choice to perform investigation of device-related injuries (see Chapter 64). Knowledge of the applications, operation, and potential problems of medical devices is an important factor in the ability to analyze a situation and to reach conclusions about the manner in which a device might (or might not) have contributed to an injury. The clinical engineer is the primary person who can combine an understanding of the device with the clinical situation in which the injury occurred, to provide information on whether the injury was attributable to the device or other factors.

In many cases, there is a propensity to blame the equipment or device for an injury, without understanding the mechanism by which the injury occurred. In 70 to 80% of the cases of reported malfunction of a medical device, the item is found to be operating as designed when tested. The ability of a clinical engineer to unravel the variety of circumstances surrounding a device-related injury is an important contribution to the investigative process, which may also involve risk managers, nursing staff, manufacturers, and others.

In the event that a severe injury or death leads to litigation, the investigation performed by the clinical engineer may become an important part of the litigation process. If this occurs, the investigator may be called upon to function as an expert witness. In this context, the information gained during the investigation, and the conclusions reached, will be subjected to scrutiny by attorneys, opposing experts, and the court system. The clinical engineer will then be exposed to an entirely different system than the objective analysis performed in the engineering arena. The person's experience, qualifications, methodology, results, and conclusions will be examined and questioned. The expert also will be expected to analyze the opinions of the opposing side and to assist in developing positions that will be taken in an attempt to reach a settlement, or, failing that, to win the case at trial.

In order to be successful as an investigator of device-related injuries and to function as an expert witness when called upon to do so, objectivity and neutrality are necessary traits, in addition to the expertise and experience in the field of medical devices. This chapter will assist the reader in understanding what is required to function successfully in this role.

Qualifications to Perform Investigations

The investigation of medical device injuries is a complex task that requires a multidisciplinary approach. The investigator must have knowledge of the theory of operation of the device being investigated, an understanding of the clinical aspects of the event, knowledge of the facilities and systems that may affect the operation of the device, and the ability to work with others to obtain the information necessary to carry out the investigation.

To understand the theory of operation of a device requires knowledge of the physics and engineering principles of the operation of the device. Knowledge of electronics, electricity, pneumatics, hydraulics, optics, digital technology, thermodynamics, human engineering, and other fields may be required in various situations. One must understand how to analyze the normal and abnormal operation of a device in order to determine the ways in which a failure may (or may not) occur and contribute to an injury.

An awareness of the ways in which circumstances outside a device can result in injury is an important part of the investigative process. One common example in modern medical technology is the abnormal operation of a device caused by power-line disturbances. The investigator must continuously consider the role that failure or abnormality of a support system could play in an injury. The crossing of medical gas lines can result in a fatal injury if the wrong gas is delivered undetected through gas-administration equipment. In such a case, failure of the primary device is not the issue; abnormality of the support system is the underlying cause. It often requires a great deal of analysis and attempts at duplicating an event to determine that a support-system problem is the underlying cause of the injury sustained by the patient. Such situations require knowledge of the complex utility systems that are used in health care facilities, not merely the ability to test a piece of equipment on the bench (see Chapter 59).

It is necessary that the investigator understand basic medicine and physiology as well as medical technology. In some cases, the event being investigated has been brought on by the patient's medical condition and has no relation to the equipment and devices in use for clinical care and diagnosis. One example of this situation is the case that the author investigated, in which a patient was originally diagnosed with an electrosurgical burn and an investigation of the equipment used during the surgery was launched. Upon closer examination of the lesion and the circumstances of the patient's care, it was determined that the lesion in question was a pressure injury that had been developing over a period of time and was exacerbated by the extended time of pressure exposure on the operating table. The investigation of the electrosurgical equipment was then abandoned, and the mechanisms by which the patient sustained the pressure injury were pursued. Without knowledge of physiologic and clinical factors, the investigator would not have been able to differentiate between the symptoms and etiology of the lesion, and would have wasted time and money investigating a moot point.

The successful investigator must have the ability to work with clinical staff, both as a member of the investigative team and in the capacity of interviewing staff members involved in the event, in order to gain information about the event. In many cases, the clinical engineer will be looked upon as the leader of an investigation involving an injury that is thought to be related to a medical device. He or she will be asked to assist in making a determination as to whether the device or an error in using the device was the cause of the injury. This challenge may mean performing an independent investigation that is then reported to others, or participating on a team that may include physicians, nurses, risk managers, purchasing staff, administrators, manufacturer representatives, and outside consultants. In many cases, the results of an initial investigation will be used to determine whether or not the incident must be reported under the requirements of the United States Safe Medical Devices Act (see Chapter 126).

In this capacity, it is important that clinical engineers combine their knowledge and findings with those of others on the investigative team. Often there will be cases in which the perspective of someone from another discipline (e.g., nursing) will complement the technical investigator's findings to enable a different or more accurate description of the cause of the event to be developed. It is important that the investigator consider input from members of the team, or that information be obtained from people with expertise in other disciplines prior to drawing final conclusions. Simply saying that the equipment did not fail is not an adequate conclusion to an investigation in which the objective is to determine the underlying reasons for a patient injury.

The Investigational Process

An investigation should be a methodical process that consists of distinct steps. While some investigations will not require or not lend themselves to all of the steps described here, a general framework that will apply to the majority of medical device injury inquiries is presented here. Some of the steps will not be under the control of the investigator, and it is important that the relevant personnel be educated in their roles to ensure that the investigation is timely and thorough.

Gathering of information at the time the event occurs is critical. In most cases, the clinical engineer will not be present at the time of the event. Therefore, clinical staff must be trained beforehand on what to do when a device-related injury occurs. It is important that all settings on the suspect device be recorded, as well as the device identification and patient parameters (where applicable). This should be done as part of the confidential event report (also known by such terms as *incident report* or *variance report*) that is prepared for the facility's risk manager. Settings to be recorded can include such things as output power, rates, alarms that occurred prior to or during the event, the mode in which the device was used (e.g., assist vs. control mode on a ventilator), pressures, and temperatures.

If the device has an alarm or parameter memory, the memory contents should be interrogated prior to sequestration or commencement of any testing. If possible, it is preferable to record, print out, or download memory contents immediately after the event and before the machine is turned off, as some devices use volatile memory that will be cleared of stored information when the power is removed.

The device must be immediately identified so that it can be produced for future testing or other investigation. The manufacturer, model, and serial number should be identified in the event report. Hospital identifiers such as inventory control numbers or department identifications (e.g., ECG #4) also should be included in the identification information. Where appropriate, the most recent maintenance date should be recorded because inspection labels can become illegible or can be removed.

A request to check the device should be made by clinical department staff. The decision as to whether the check should be made by in-house staff or an outside, uninvolved third party should be made by the facility risk manager. It should be clearly stated on a service request form, attached to the device, that it was involved in a patient injury that and is not to be repaired. A brief statement of the suspected malfunction should be included in the inspection request.

Arrangements to sequester devices involved in suspected injuries or deaths should be made in advance of any untoward event. Any supplies that are needed to use the device must also be preserved, such as electrodes, cables, tubing, transducers, and solutions. These frequently provide an insight that cannot be attained by simple performance testing of a device. It is most common for sequestration to be done by the facility's clinical engineering service, but also may be done through risk management or security. In any event, the device must be secured in an area where access is limited to those who have a legitimate reason to inspect or to test the device to protect the legal position of the facility and other interested parties. It is advisable for a facility to have an "evidence locker" where devices can be secured during an investigation. Under no circumstances may a device be released to a manufacturer for evaluation without the considered consent of the facility's risk manager and legal counsel. Release of devices to a manufacturer frequently results in disappearance or repair and return of an item under investigation because of inadequate communication within the manufacturer's organization. Such an event can seriously jeopardize the facility's legal position in the event of litigation. It may be advisable to obtain the services of a disinterested third party to control the device during the investigation, in order to prevent allegations of spoliation of evidence.

The investigator must have the ability to perform information-gathering interviews in a nonjudgmental and nonthreatening manner. It is extremely important that the investigator obtain as much information as possible from those who witnessed the circumstances of the injury. In some cases, these people will be afraid of possible recriminations, simply because they were present at the time the injury occurred. In conducting interviews, the investigator must be viewed as an ally rather than a threat to the staff member. It is also essential that an air of trust be built with the staff member being interviewed. The investigator must have the ability to make the interviewee comfortable with the information gathering process. Conversely, the investigator must be objective—not interjecting personal opinions and not leading the interviewee's responses. An investigation must be handled as a fact-finding mission; all elements of blame must be eliminated if the process is to be successful. It is often best simply to ask the interviewees to describe in their own words what happened, without making any preliminary statements that might color their responses, and then to ask questions based on the event description provided. It will be common to get different descriptions from different staff members. This will depend on their respective function during the event, educational level, experience, and anxiety over the event. The investigator's job is to synthesize all information into a reasonable description of the event so that it can be used in the causation analysis.

Obtaining information on the event is a crucial step in the investigation, but it is often minimized or overlooked. It is not sufficient simply to test a device to determine whether it meets its operational specifications and to report that the problem could not be reproduced. Information on the event will often reveal circumstances that must be considered in order to obtain a meaningful simulation of the event in question. Arrangements should be made to interview all staff members who were present at the time of the event. It is best that the interview of an individual staff member be performed by the investigator with no other people present. The interviewee must be made to feel at ease and assured that the process is not meant to establish fault or to assign blame. Initially, the interviewee should be asked simply to give their account of the event from their perspective. This account then may suggest questions that can be asked in order to elicit additional information. The investigator should have questions in mind to ask to provide information needed in the event that this is not brought out in the initial stage of the interview. The interviewee should be asked which other people were present at the time of the event. It is useful to ensure that such people are included in the interview process if they have not previously been contacted. The staff member should be assured that their information will be kept confidential and used for analysis of the event, not to assign blame. They also should be reminded not to discuss the event or the interview with other parties, in order to preserve confidentiality and to ensure that other parties are not influenced by the interviewee's account and opinions.

Device identification is critical to the investigation. There should be no doubt that the device tested is the actual unit involved in the event under investigation. The device must be photographed on all sides and identification labels (e.g., manufacturer model and serial numbers, owner identification tags, and inspection tags) should be photographed and documented.

The next step in an investigation will be the inspection and testing of a device. It is important that any initial testing be nondestructive. Prior to testing, the unit and all accessories must be visually inspected for damage or contamination that would affect proper operation. The unit and accessories should be photographed, with attention paid to any abnormality found through visual inspection. Equipment covers should be removed where feasible, and the interior inspected for physical damage, contamination, or evidence of abnormal operating conditions (e.g., dirty contacts, overheating, leakage of fluid, or loose connections).

Testing should begin with a functional and safety test of the device to determine whether it meets its operating specifications. The unit should then be tested in the mode in which it was being used at the time of the event, and an attempt should be made to reproduce abnormal conditions to determine the way the item responds. It should be noted whether appropriate alarms occur, the unit switches into a backup mode, or other changes in normal operation of the unit occur. Such testing often will require that staff interviews,

event reports, and medical record reviews have been performed prior to testing to determine the circumstances of the event for reproduction during testing.

Equipment and facilities required for inspections can vary greatly. Often the only items needed are those found in a typical, basic clinical engineering laboratory. These will include simulators for ECG, arrhythmia, respiration, blood pressure, temperature, and pressure/vacuum. Basic test equipment for checking the most commonly encountered equipment should include a digital multimeter with interchangeable probe leads, electro-surgical power output meter, digital pressure/vacuum gage, defibrillator output meter, test lung, analytical grade graduated cylinders (10, 100, and 250 ml are useful sizes), stopwatch, digital thermometer with surface and immersible thermocouples, and oxygen monitor. Where more specialized equipment is required, it can be rented from medical test equipment manufacturers, electronic test equipment rental services, or other rental services.

Items used in inspections are the basic tools that one would find in a biomedical service shop. Typical inspection tool sets will include English and metric socket wrench sets; an interchangeable blade screwdriver set with multiple sizes of straight slot, Phillips, and Torx blades. Needle-nose chain nose, pump and slip joint pliers should be included along with a wire cutter/stripper, small hammer, crescent wrenches (a #6 wrench to quite useful), jewelers loupe, hex and spline key wrench sets, jewelers screwdriver set, tape measure, English/metric ruler, hemostat, dental pick, and scalpel handle with disposable #11 blades. A lab coat, safety glasses, supply of exam gloves, and paper towels should be carried for protection from, and cleaning of, potentially contaminated items. Resealable-zipper closure plastic bags in various sizes are useful for packaging and preserving items, and biohazard bags should be available for transporting and storing biohazardous or infectious items.

The investigator also must ensure that test equipment is easily portable as it is often desirable to perform the inspection on-site in conjunction with staff interviews. Custody of items should be retained by the facility and its risk management staff, or the attorneys might not be willing to allow the subject equipment to be removed. It is advisable to have separate photography equipment and tool/equipment cases that can easily be transported to an inspection site as some inspections are visual only and will not require the use of tools or test equipment.

Good-quality photography equipment is necessary for documenting the facility and equipment involved in an investigation. It often will be necessary to have specialized photography capability available, such as macrophotography to obtain the detailed views necessary to properly document an inspection or to photograph small items. One of the biggest problems in properly documenting an inspection is lack of proper photographic equipment. Whether film or digital equipment is used, it must be versatile and be capable of high resolution. Cameras that have interchangeable lenses are recommended so that the best lens for a particular application can be selected. Typical lenses used are a 35-to-70-mm zoom lens and a 60-mm macro lens with ring flash. A wide-angle, 28-mm lens is useful for photographing entire rooms or equipment setups. This latter will also require a suitable flash, as most built-in flashes do not have the power or coverage angle required to obtain good-quality, wide-angle, interior photos. Videotaping equipment is useful for recording a simulation of an event or where a detailed continuous record of an inspection is needed. Depending on what is being done, additional sound and lighting equipment may be necessary to obtain a good-quality videotape.

There will be times when specialized equipment is necessary to perform the appropriate testing of the device. As stated above, it may be necessary to rent equipment from medical or test equipment suppliers and to ensure that the use of the equipment is understood to obtain accurate results. At times, the manufacturer is the only source of specialized jigs or test equipment unique to the device, so they may need to participate in the testing. When this is the case, the testing should be observed by the investigator and an agreed-upon protocol designed to preserve the integrity of the device. The device should remain under the control of the investigator at all times and should be returned to the health care facility when testing is completed. In cases where destructive testing is necessary, all parties involved must agree to it via a signed document with each party's representative assenting to the agreed-upon protocol and the fact that the testing will damage or destroy the item.

Under some circumstances, it will be necessary and desirable to have analytical tests performed by outside laboratories or other experts. In such cases, it is important to ascertain the qualifications of the individuals performing the tests as well as their experience in forensic testing. Examples of such third-party testing would be metallurgical laboratories, analytical chemists, mechanical engineers, and electrical/electronic engineers. When such resources are used, it is important to have a test protocol submitted and agreed upon prior to authorizing such work. Charges of spoliation of evidence can severely weaken a case, and it is important to know the state laws that will be applicable in litigation, in order to ensure that a device is handled in such a way as to avoid these charges. It also must be remembered that the results of outside, third-party testing must be handled properly by the expert, in order to preserve confidentiality and to prevent premature discovery by opposing parties.

Where the inspection and testing process involves removal of the item from the premises where the event occurred, the chain of custody must be preserved. This involves documenting every event in which possession of the item is taken by another party. For example, if the expert delivers the item to an outside testing service, then stores it at the expert's office, and then returns it to the facility that owns it, each step must be recorded. The person releasing the item and the person receiving the item must both sign a document that indicates the description and identification of the item, the date and time it was released into custody of the individual receiving it, and the purpose for the transfer of custody. Such information is necessary for both tracking the item, to ensure it is not lost, and to be able to determine all of the parties who have been involved in handling the item in the event of damage or unauthorized repair.

The final phase of the investigative process is the information-gathering phase. This involves the research necessary to determine whether the event in question has been observed and reported before, or is a unique event. There are a variety of resources available to the investigator for this information. The Manufacturers and Users Device Experience (MAUDE) system, which is the FDA Center for Devices and Radiological

Health's medical device reporting database, is an excellent starting point. In addition, access to the Health Devices user reporting system provides a great deal of information on events that do not meet the reporting criteria for health care facilities and manufacturers under the Safe Medical Devices Act. MedLine searches for articles and abstracts relating to problems with the subject device are additional sources of information. If it is not feasible to perform this research in-house, a local database-search firm can provide these services. In using such firms, it is important that all of the search criteria be well defined and that all of the possible search parameters be provided to the service. There have been many incidents of information not being retrieved because the search firm was not given appropriate criteria, thus resulting in a search that failed to reveal information that was immediately available if the proper search criteria had been entered.

In addition to researching external information sources, a basic part of the investigational process is reviewing internal documentation. Such documentation includes the operating policies and procedures of the facility, product literature, manufacturer processing and service instructions, professional processing and sterilization guidelines appropriate to the devices' manufacturer warnings, and the medical records and event reports relating to the incident being investigated. Care must be taken to gather all information and staff opinions before starting to formulate conclusions about the event. It is important that the investigator review all information available before forming opinions. Credibility of the investigator can be severely compromised if new information is revealed that significantly contradicts opinions and conclusions expressed by the investigator.

Reporting

Many investigations are compromised or fail because of inadequate reporting. The device investigation report is described here. The report should be written in a style that can be understood by both nontechnical and nonmedical personnel. The report, whether oral or written, is the best tool by which to educate other parties involved in the incident under investigation. Written reports should include an introduction to the event being investigated, the device description, inspection and functional test results, staff-interview results, observations, conclusions, and recommendations for prevention of future events and injuries. A recommendation as to whether the event should be reported under the requirements of the Safe Medical Devices Act should be made. Under some circumstances, the party requesting the investigation will not desire written reports, and none should be prepared unless specifically requested.

The introduction should summarize the reason for the investigation, a brief description of the device(s) involved, a summary of the event and outcome, the date of the event, the date the item in question was sequestered, and the date of the investigation. The equipment identification section should follow, identifying all devices and supplies by description, manufacturer, model number, serial/lot number, inventory number, equipment-control number, and expiration date as applicable. Where inspection tags are affixed to the device, the date of the most recent inspection should be documented. The device and facility evaluation (as applicable) should include descriptions of the devices and tests performed. Results of visual inspections and performance tests should be reported objectively, with no comments or conclusions made in this section. The observations section will include the investigator's comments on the test results.

The staff-interview section is provided in order to summarize the information obtained by discussing the event with staff members. Ideally, information obtained from staff members who were present at the time of the event should be presented in this section. Where this is not possible, third-party descriptions or accounts of information obtained from those involved in the event should be obtained and reviewed. Ancillary personnel involved in any internal inspections or investigations should also be interviewed in order to obtain any information that they might be able to provide that would allow for a more complete report. It is important to identify the persons interviewed, their positions, and their functions at the time of the event, in order to provide perspective on their information and to permit follow-up if and when needed.

The investigator should summarize findings and relate the event to test results and staff-interview information in the observations section of the report. This section is used to synthesize the information obtained through the inspection, testing, and interview processes. The observations section is also used to comment on test results, clinical conditions related to the event, and the possible mechanism by which the event occurred.

If possible, the conclusions section of the report should state the reason for the event and the cause(s) of the event. The conclusion might be that a particular device failed in a certain manner; that there was an error in setting up or using the devices; that the device design contributed to the problem; or that the event was related to a patient condition and that it was not the result of a device-related problem. At times, it may be necessary to state that there are insufficient data or inconclusive results, and that a final conclusion concerning the reason for the event cannot be reached with the information available.

It is often helpful to provide recommendations for preventing future repetition of the injury or conditions that, under different circumstances, could result in injury to the patient. Whether to include this section depends on the nature of the original request for the investigation. Where an investigation is requested by a facility's risk manager as an internal matter, it is often helpful to provide suggestions for changes in procedure, training of staff, or changes or modifications in devices or equipment. Where the investigation is requested as a result of litigation, such a section generally would not be appropriate, as all that is desired is an objective report of the facts of the situation that occurred and the expert's opinion as to the cause of the event or injury.

When a written report is not created, it is important that the investigator maintain all notes, documents, and photographs in a manner that will enable the presentation of an oral report. An oral report must be based on documented findings. Good notes are essential, in order to prevent misquotation at a later time or having one's information taken out of context in the event that litigation ensues. The investigator will usually be called upon to provide an oral report to the hospital's administration, the risk manager, or defense attorneys representing the hospital in litigation. Under such circumstances, the information

obtained during the investigation process must be revealed only to parties who are authorized to communicate with the investigator.

In providing a report, either written or oral, the investigator must consider various issues. A disclaimer should be provided on a written report that protects the confidentiality of the document and guards against unauthorized discovery in jurisdictions where the law protects such reports. The report may have "Confidential" stamped on each page. Another approach is to place the statement "Prepared on Request of Counsel in Anticipation of Litigation" on the title page of the report. Identification of the patient involved must be discussed with the person requesting the investigation, as policies vary widely on this matter. Some facilities request full identification of the patient by name and medical record number, while other facilities want patient identification withheld from the report. Not being aware of the policies of the institutions for which the report is being prepared can be a major pitfall for the unsuspecting reporter.

First and foremost, the investigational report must be objective. There is no place for editorializing or subjective criticism that is not based on established fact in an event analysis. Any criticisms included in a report must be nonjudgmental and written in a constructive manner. No effort to place blame should be made, as to do so could unfairly jeopardize an individual or the institution. Efforts should be made to view the found problems from a systems approach rather than establishing blame. Political considerations also must be eliminated, to the degree possible, from any objective investigational report, as they interfere with performing an objective analysis and forming conclusions that will be meaningful to the institution. For further information on reports, see *Writing and Defending Your Expert Report* (Babitsky and Mangravitti, 2002).

Activities Resulting from the Investigation and Reporting Process

The investigator often will be requested to perform various types of follow-up activities subsequent to generating the investigation report. These may range from simply answering questions to participating in litigation. In the majority of cases, the investigator will not become involved in litigation. (This is a separate issue that will be addressed later in this chapter.)

The investigator may be called upon to make a presentation to an administrative group or medical committee concerning the findings. This usually will involve providing a summary of the event, explaining the theory of how the event happened, and reviewing ways in which a recurrence can be prevented. Frequently there will be pointed questions from the audience. These should be anticipated, and responses should be prepared, to the extent possible. The presenter should be aware of who will be at the meeting and their possible issues in order to provide meaningful information and suggestions.

Implementation of recommendations frequently will require the assistance of the investigator and may include training of staff by way of in-service presentations, which may be requested. Recommendations on the modification or development of policies and procedures in conjunction with department management may be an important follow-up action. The investigator may be requested to attend meetings with manufacturer representatives and to participate in manufacturer inspections. In such situations, the role of the investigator should be primarily that of observer, making individual notes and gathering any additional information that may result from the manufacturer's activities.

Interaction with governmental and enforcement agencies is a frequent product of medical device investigations. This may involve compliance with regulations under the Safe Medical Devices Act, if the event occurred in the United States, or similar legislation in other countries. (See Chapters 125 and 126.) Assistance in making reports to governmental agencies may be requested either in the form of helping to fill out documentation or participating in inquiries initiated by a licensing or enforcement body. On rare occasions, an investigator may be requested to participate in formal government activities such as advising on modification or implementation of laws or participating in agency meetings or public hearings.

The Clinical Engineer as Expert Witness

In the event that litigation ensues over a medical device-related injury or death, the clinical engineer may be called upon to act as an expert witness in the matter. In this capacity, the clinical engineer's training and experience will be relied upon to provide analysis and opinions concerning the event being litigated. It will require research to support or refute positions taken by parties to the litigation, working with attorneys preparing the case, and possible testimony at depositions and trial.

The clinical engineer may be designated as an expert to represent an employer or he may be retained as a third-party expert via an insurance carrier or a law firm. While there is an assumption that the clinical engineer will support the position of the retained party, the expert nevertheless must maintain neutrality. An expert witness should function as a disinterested third party whose responsibility is to provide opinions based on the facts of the case and research and testing performed by him. The expert is the only person who is allowed to express opinions in court rather than being limited to simply reporting facts. However, these opinions must be based on theory and information that is accepted practice in the person's field of expertise. Courts rely on experts to educate the court and the jury on the circumstances of a case and to provide opinions on the matter that will be considered in the jury's development of a verdict.

Qualifications to Be an Expert Witness

An expert witness is a person who must demonstrate that he or she is competent to research the circumstances of a case and to reach meaningful conclusions and opinions that the court can rely on. In order to meet this requirement, an expert must pass court

tests of competency, which examine the expert's background and credibility. The expert is the person who has special knowledge of an area that is not considered to be in the body of knowledge of the average citizen or that is not discernible by common sense.

Education and special training comprise one of the main criteria used in qualifying prospective experts. The person being considered must have education and training in their field, and it must be significantly greater than that of the common man. In general, the person must have at least an undergraduate degree in, or related to, their field of expertise. In addition, an expert must show evidence of specialized training in the field in which testimony will be offered. This may consist of additional educational credits, attendance at specialized training courses, participation in professional associations related to the field, and certification or licensure in the field. In the case of clinical engineering, this would mean having an undergraduate degree in clinical engineering or related engineering fields with additional training in medical and biological sciences, at a minimum. It also might be possible to qualify with a degree in life sciences or medicine, augmented by training in engineering and technology.

An expert witness must have demonstrated experience that is relevant to the area of proposed testimony. As an example, a person with experience in design of equipment could be expected to testify concerning design defects, but not about the clinical use of a medical device in the operating room, as it is unlikely that a design engineer has spent much time working on surgical cases in an operating room. The amount of experience also must be sufficient to satisfy the court that the person has sufficient knowledge of the field. It is unlikely that a person who has completed their degree, but has no working experience in a field, would be accepted as an expert. Conversely, a person who has only a high-school education but many years of practical experience, such as a machinist or electrician, could qualify.

Credentials are another aspect of the expert's qualifications. A person who is certified as a clinical engineer, a registered nurse, a registered professional engineer in a relevant field, or a person with medical board specialty certification is favored as an expert witness in the field over a person with a similar background who lacks such credentials. Many attorneys require that their experts have a higher degree and/or professional certification of some type to ensure credibility with the court and the jury.

Another basic requirement to function as an expert witness is the ability to communicate. One of the most important functions of an expert witness is to teach the jury so that it can understand the expert's testimony. While clinical engineers are accustomed to working with peers who have knowledge and education in medical and technical fields, as an expert they will be working with people who generally have little or no understanding of engineering or medicine. In addition, it must be considered that the average educational level of most juries is a high-school education. Therefore, it is important that the clinical engineer who wishes to work as an expert witness be able to simplify and to explain medical and engineering concepts to those who have an advanced education but little technical training (e.g., judges and attorneys) and to those whose educational level might not include high-school graduation (i.e., jurors). This must be done as an educational effort at the level appropriate to the audience, and it must not be perceived as technical jargon or as the expert speaking down to the audience. Lack of this ability has been the downfall of many highly educated theoretical experts when juries have been polled after the conclusion of a trial.

The expert also must be able to function psychologically and emotionally in the environment of the legal system as it operates in most jurisdictions. He will be alternately supported and criticized by the various parties to a lawsuit. He must be able to interact objectively with attorneys who are defending their clients' positions by attempting to undermine or disqualify the expert. Many people who have been educated in engineering are not oriented to working in the adversarial atmosphere that characterizes a legal case. During deposition and cross-examination at trial, the experts' background, research, findings, and opinions are challenged, and the expert must be well prepared to defend against these attempts to disqualify them as experts. (See *Cross Examination: The Comprehensive Guide for Experts* (Babitsky and Mangravitti, 2003).) It is important that the prospective expert not take personally any criticism from opposing parties. Conversely, part of the expert's function is to find and exploit the weaknesses of the opposing expert's experience, background, and opinions. Many otherwise well-qualified clinical engineers simply do not have the personality to operate within the emotional atmosphere of litigation.

One of the most important characteristics of a successful expert is neutrality. It is of utmost importance that the expert not be swayed by the emotional issues that arise in medicolegal cases. The expert is probably the only figure involved in the litigation who does not, and should not, have a vested interest in taking sides in the action. The expert must be able to see both sides of a case and to consider them objectively. If the facts dictate a position that is not in favor of the party who has retained the expert, this must be brought to the attention of the attorney with whom the expert is working. One of the services that the expert provides is to be the devil's advocate and to point out weaknesses in the case of the side that has retained him or her. This will assist the attorney in preparing to plug any holes in his arguments and to develop approaches to strengthen the weak points in the case. In some cases, this information may speed settlement of the matter and thus avoid the expense and time associated with a trial that could result in an unfavorable verdict.

Under no circumstances must the expert have any vested interests in the outcome of the case at hand. All offers of contingency fees must be rejected, although compensation is appropriate for the expert's assistance. The expert should have no investment or other monetary interest in any of the parties involved. For example, if the opposing counsel determines that an expert owns stock of a company involved in the case, this fact will be brought out in depositions and court testimony in attempts to disqualify the expert or to undermine the expert's credibility with the jury.

Developing Opinions

The opinions of an investigator or a retained expert are sought either to resolve a problem at the health care-provider level or to assist in litigation. The primary reason for retaining an expert in a legal case is to present opinions to the jury that support the contentions of

the side that has retained the expert. In order to express such opinions in court for consideration by the jury, a process must be followed by which valid opinions are developed. If the bases for the opinions expressed do not meet the criteria of the court, the expert's opinions will lose credibility and the expert can be disqualified by the court. Therefore, opinions developed by an expert must be based on provable facts, test results obtained by established methods recognized in the field, and information researched from credible sources.

Among the sources for information upon which to base an opinion are published reports and journal articles in the field. Reports of findings by other experts in the field can be used to back up the opinions developed by the expert, or they can provide reasons to modify them. Such information can be obtained by reviewing technical articles that are pertinent to the area of concern and compiling relevant information. Results of research in a field, government studies, and reports by users, such as the medical device-related reports submitted to the U.S. Food and Drug Administration (FDA), can all provide information to support or refute an expert opinion.

Reviews of the deposition transcripts of other parties involved in the litigation are an important part of developing and supporting expert opinions. It is important to obtain information from witnesses' descriptions of events in order to ensure that the event is fully understood. It is quite possible that one line in the deposition of a seemingly unrelated witness can confirm or disqualify an opinion that an expert has arrived at prior to reviewing case material. It is also important to determine the opinions of opposing experts and their bases for such opinions. While deposition transcript review is often a long and arduous process, it is a valuable source of information for the expert.

Current news reports and magazine articles also can be sources of information that are relevant to the expert's opinions. Reports of successes or problems with a device that is under litigation may act as additional contemporary supporting material for the expert. While it is important to avoid sensationalism in using such reports, they can be valuable supporting material if used properly.

The expert is allowed (and expected) to rely on his or her own experience in formulating opinions concerning a case. Part of the reason why an expert is retained is to provide information based on experience in the field. It is perfectly acceptable to say, "In my twenty years of experience in the field, I have seen this happen often", and then proceed to express opinions on the cause of the event. It is important, however, for the expert not to express opinions in areas where experience is marginal or the expert is not fully competent. A skilled opposing attorney will quickly discern the expert's inexperience and/or weakness in knowledge and will turn it against him. The expert also must guard against being led into an area where he has little or no expertise because he could be asked questions that he could not answer, or he could express opinions that he could not support.

The Litigation Process

In the event you are requested by an employer or retained as a third party to act as an expert witness in litigation, it is important that you understand the general process. This section provides a brief outline of the litigation process as generally followed in the United States and many other countries from the viewpoint of a practicing expert witness.

When an action is filed, both sides begin to prepare their cases. To obtain the information that is necessary to support each side's contentions, the "discovery process" is initiated. This process involves the gathering of information from a variety of sources, including the opposing party. The discovery process may include requesting information and reports from the opposing side, setting up inspections and testing by all parties witnessed, performing searches for information that is relevant to the case, and interviewing all parties involved in the case. There are rules and time limitations concerning discovery that vary among jurisdictions, which the expert should become familiar with in order to ensure that time constraints are observed and that no rules of discovery relating to expert witness activities are violated.

Reports may be prepared at the request of attorneys to assist them in supporting their position in the case. In many cases, the plaintiff's attorneys will request written reports from expert witnesses to use in obtaining information from the defense. In some jurisdictions, experts must prepare reports including supporting facts and opinions that are submitted to the court prior to trial. These reports are then distributed to the litigants for use in trial preparation. In many cases, an expert's reports of investigations will be protected from discovery until the person is designated as an expert for trial. Protection of reports from discovery varies greatly among jurisdictions, and the experts must always assume that their reports will be read by the opposing parties at some point in the litigation process, and that they also could be shown to the jury.

Designation of experts is the formal process by which each side reveals those whom they plan to present as experts at trial. The designation permits the opposing side to review the qualifications and background of the person designated. In many cases, research is done on the expert to determine what cases they have worked on previously as well as their success rate, and to read reviews of their performance. In a process that is related to expert designation, attorneys may work with the experts whom they have retained, to develop a declaration of the expert's opinions concerning the case in order to support efforts to reach a settlement of the case before going to trial.

In most jurisdictions, depositions are taken in which each side is allowed to question the opposing expert(s). This is done under oath, usually in the opposing attorney's office. The proceedings are recorded by a court reporter, and a formal transcript of the deposition is produced and provided to all sides. The expert is required to bring all notes and materials reviewed in forming opinions to the deposition for inspection by the opposing attorney. During the deposition, the expert is questioned on his background, qualifications to provide opinions on the case in question, his opinions, how he has arrived at his opinions, and the facts supporting those opinions. The attorney who retained the expert will accompany him and will have the option of objecting to questions or comments made by the deposing attorney. In some cases, the expert will be instructed not to answer certain questions posed by the deposing attorney. Depositions

vary significantly in time, with some as short as 30 minutes, while others have lasted for ten days or more, spread out over several weeks or months. After the deposition is completed, a printed transcript will be sent to the expert by the court reporter for review and correction. At that time, it is important that the expert review the transcript for technical and factual errors, and correct them. It should be noted that if there are major changes made to answers or opinions, this may be used in court by opposing counsel to attempt to embarrass the expert and impugn his integrity. For further information on depositions, see *How to Excel During Depositions: Techniques for Experts That Work* (Babitsky and Mangravitti, 1999).

Many cases (80 to 90%) settle before going to trial. However, the expert witness will testify at trial in those cases that have not been settled. When called to trial, the expert's testimony will revolve around the same items that were covered in the deposition. Sufficient time should be reserved for pretrial preparation to review the notes made in the case and the deposition transcript. It is important that the expert spend time with the attorney retaining him, to discuss what the expert can expect to be confronted with at trial, as well as any new information about the case. At trial, the expert must be careful in understanding the questions asked, before responding. It is not uncommon for opposing counsel to ask a question in several different ways, to elicit different answers and thereby impugn the expert before the jury. Prior to actual questioning, the opposing side might attempt to disqualify the expert at trial by asking a series of questions concerning the expert's background and qualifications.

When testifying in court, the expert should always remember that the jury, and not the questioning attorney, is the audience. Dress and appearance should be conservative and professional. Excessive jewelry should not be worn. It is important for one to look at the jury members and acknowledge their presence. Experts must explain their positions and information in terms that the jurors can understand, as few if any of them will have a technical or medical background. The expert must make an effort to develop a rapport with them so that they will pay attention to the testimony while not violating the court's rules governing interaction with the jury that could result in a mistrial. When testifying, it is important that the expert take time before answering. It is perfectly acceptable in most courts to bring the case file to the witness stand for reference prior to the expert answering a question. This process also gives the expert time to formulate answers and to control the pace of the questioning to a comfortable rate. Normally, an expert will be excused after the testimony is completed. However, it may be necessary for him to be available for recall if instructed by the court or retaining attorney.

When the trial is completed, the retaining attorney generally will advise the expert of the outcome. If the attorney does not communicate within a reasonable time, it is perfectly acceptable for the expert to contact the attorney to learn the verdict. The expert may ask for a critique of his work on the case, as a guideline to areas that can be improved.

The Business of Being an Expert Witness

While many clinical engineers will be involved as investigators, and some may testify as part of their function as employees of health care organizations or manufacturers, there are some adventurous souls who desire to work as third-party experts on a part-time or full-time basis. To do so successfully requires knowledge of the business-management aspects of acting as a third-party expert. (See Chapter 12.)

Establishing a fee structure is an important first step in the process of establishing a practice. Fees are generally charged on an hourly basis for the work performed, and they are dependent on the qualifications of the expert, the general fee structure in the area where the expert is practicing, and rates charged by the competition. There is no specific rule for the hourly rate, which can range from \$100 to over \$500. Most experts charge a higher rate for trial and deposition testimony, commonly 25-50% more, due to the stress of examination by the opposing side. It is not uncommon to specify a minimum time to be billed for a deposition, such as two hours or half of a workday. If there are other expert witnesses or forensic organizations in the expert's area, they can provide guidelines. Attorneys who use expert witnesses can also provide information on the fees they are accustomed to paying. It is important that a detailed time log be maintained in order to make billing simpler and to justify charges in the event that billings are questioned. It is common practice to charge in quarter-hour increments. Local travel is charged at the hourly rate, with some experts charging for round-trip travel, and others only for one-way. Long-distance travel via air or other carrier is often negotiated with the client. Many experts take work with them, so the travel time is charged as regular work time. Alternatively, work can be done on other cases during travel time to provide income while traveling, as most clients are unwilling to pay an expert to sit on a plane.

It is important that the expert have a signed agreement defining fees and terms of engagement prior to starting work. A contract or letter of agreement should be presented to the client when the client indicates an intent to engage the expert. This document should reference the case assigned to the expert, include terms and conditions, and specify the hourly rates for research and preparation and testimony at depositions and trials. Payment terms must be specified and should require that the expert be notified in advance of any cap or limit on fees, time frame for completion of services, and changes in the nature of services required. There must also be a "stop-work" provision, which specifies that the expert will discontinue work on a case if the client's account falls in arrears. It should be a condition of engagement that all amounts due be paid prior to the expert's appearance at depositions or trial, as a settlement that eliminates the need for further work from the expert may be reached.

When dealing with plaintiffs, it should be stated that payment for the expert's services is not contingent on funding by a third party. This is necessary to protect the expert, as plaintiff's attorneys often work on a contingency basis and the expert could be placed in the position of trying to collect from a third party when working on a plaintiff case. Another item to consider in the agreement is the requirement that all retainers be paid in advance when working on plaintiffs' cases because a plaintiff's attorney could refuse to pay the expert's fee after an unfavorable verdict, claiming that they did not get their

contingency, that they were unable to collect the monetary award, or that the client has no money left, due to the cost of pursuing a case that resulted in no monetary judgment being awarded. A significant advance (at least \$2,000) retainer should be collected prior to reviewing a plaintiff's case. This acts as a screening device to ensure that the attorney has faith in the case. It also protects the expert from being unable to collect for initial work performed if the case settles or the attorney decides not to pursue it after receiving the initial comments from the expert review of the merits of the case.

Invoices to clients should be done as monthly progress billings unless mutually agreed to by the expert and the client. For short projects such as equipment inspections, or where a lump-sum billing has been agreed to, this may require only one invoice. However, most legal cases will last a year or more, and progress billings will be necessary. It is advisable to use a timekeeping system that can be easily incorporated into the billing process, and there are a number of software programs that prepare billings from input to project time sheets. This will minimize the time and effort involved in billings and will reduce lost time due to forgetting to record time or making transcription errors. The invoice must include the dates of service; a brief summary of the work performed; the hourly rate charged and the total hours billed by each person working on the case; any out-of-pocket expenses incurred on the project; and the total cost. Payment terms should also be stated (e.g., 2%; 10 days; Net 30 days; a service charge of 1.5% monthly to be charged on all past due amounts).

If a client is overdue more than 30 days on payment, an overdue notice should be sent requesting payment within ten working days. In some cases, it becomes necessary to suspend services to a client. One reason for taking this action is due to nonpayment. If there is no response within that time frame, the expert should send a letter warning the client that work on the case will be suspended if payment is not received within 60 days after the bill was rendered. In order to prevent this fate, it is important that the expert track all accounts in order to ensure that they are current.

Another possible reason for suspension of services is that the expert has exceeded the amount of work authorized. The expert must guard against performing more work than an advance retainer will cover in a plaintiff's case, or more than was authorized by an insurance carrier or law firm in a defense case. It may be very difficult to collect after the fact for work done in excess of the amount authorized because of the efforts to control costs of litigation on both sides. The expert cannot afford to think that the client has given him *carte blanche* when signing the retainer agreement.

Business resources will become more important as the income generated grows. The expert should have the support of a bank, a small-business accountant, and an attorney if he or she develops a significant volume of business. To avoid some of the pitfalls of retainer agreements and the possible legal problems associated with a consulting practice, it is advisable to develop an association with an attorney who is familiar with collections and/or contract law. There will be times when a well-worded letter from an attorney will bring about payment that has not been forthcoming. If the business becomes a major source of income, accounting and tax preparation should be done by an accountant who specializes in small business. This can be a valuable resource in preparing statements that may be needed when applying for credit lines or business loans. In addition, business-related tax deductions can be maximized to reduce taxable net income through the services of a knowledgeable accountant. Bank affiliations can be a valuable asset. Establishing credit with a small bank is a valuable asset for an expert who depends on his or her practice for all or a significant portion of annual income. Because the cash flow in this type of business is sporadic, a full-time consultant should have a small-business credit line that can be drawn against when cash flow is poor and that can be repaid when income improves. One major warning is to not use a home mortgage to finance your small business. In the event that the business is unable to generate the funds necessary to make loan payments on time, it is possible that the lending institution would foreclose on the house. Small-business owners have lost their homes because of such circumstances.

Marketing of the expert witness can be done in a variety of ways. One effective method is to purchase listings in the expert directories published by the local bar associations in the area where the expert practices. The expense of such listings can be repaid by obtaining one good case through the listing. The local or regional bar associations can be contacted to determine whether they publish such directories. Professional speaking engagements with local risk management and attorney groups are another excellent way of gaining exposure to potential clients. Such organizations are constantly looking for speakers for their meetings.

Referral services are another aspect of the expert-witness business that must be considered. These services match attorney inquiries with experts in the field, as the case requires. In return, they often require the expert to discount the fee charged to the referral service. They then bill the market rate to the attorney, with the difference being their income. In some cases, the referral service will accept the full rate of the expert and add their percentage to that rate. In the first case, the expert is giving up 25 to 50% of fee income in exchange for the referral. Where the service adds to the expert fee, it creates a

danger of reducing the number of cases that will be received if potential clients perceive the total fee as excessive. However, use of referral services can be a good way of building an initial practice. The expert should review the terms and conditions carefully before enlisting in such a service. There is no guarantee that the service will obtain any cases for the expert, and cases referred to the expert will not necessarily be appropriate. Payment of the expert will occur only after the referral service has been paid by the client, so the expert's income is dependent on the referral service's billing and collection practices. Many services also prevent the expert from accepting work directly from a client for a period of several years after a referral. This practice can limit the expert's ability to develop an independent repeat-client base.

When entering into an agreement to become an expert witness, an individual must consider the possible conflicts that may affect his or her effectiveness. Some people are not comfortable working for both plaintiff and defense attorneys and thus limit their practice to serving one or the other category of litigant. This can be used by an opposing attorney to question the expert's neutrality and must also be considered a possible factor in limiting the expert's practice. Prior commitments that will limit the expert's ability to perform work within the schedule set by the attorney or the court must be considered before accepting a case. The ability of an expert to respond to the client's needs will be considered in the decision to retain an individual. In addition, failure to meet the client's schedule can often mean that no further business will come from that client. Inability to respond to litigation issues because of lack of results from the expert places the attorney in a compromised position and could jeopardize the case. Conflicts can arise when a plaintiff asks the expert to participate in a case for a previous client whom the expert has defended on multiple occasions, such as an insurance company or corporate entity with whom the expert has a longstanding relationship. The converse also can occur. It is best to reveal these facts to the inquiring attorney so that they are aware of the potential conflict. As a general rule, the expert should engage the first party who requests his services unless the expert has a history of working for the opposing side on multiple cases. It is important to maintain a balance between defense and plaintiff work so as to avoid a reputation of being too closely allied with either category. If simultaneous inquiries occur on the same case from opposing sides, it is best to work for the side that initiated an inquiry first, unless the expert feels strongly that they wish to work for the opposing side because of previous relationships or the merits of the case.

Whether simply performing an inspection or functioning as a key expert in an extended litigation, the investigator and expert must always be conscious of confidentiality and protection of client information. No investigation or ongoing litigation should be discussed with any person who is not directly involved in working with the expert and representing the interests of the expert's client. Divulging any information about a case to other parties must be strictly avoided. There is no way to know whether the person at the next table in a restaurant, or a new acquaintance at a party, has some relationship to the litigation, or whether they are a relative of a patient whose injury is being investigated. In addition, private investigators have been known to use false credentials to gain credibility with an institution's staff or a person involved in a legal case in order to obtain information for the opposing side. All reports to clients should be marked as confidential, and no information should be revealed to other parties unless the permission of the client is obtained or in compliance with a court order which has been discussed with the attorney for whom the expert is working.

Careers in Facilities

Bruce Hyndman

Director of Engineering Services,
Community Hospital of the Monterey Peninsula
Monterey, CA

In the early days of hospital-based clinical engineering programs (usually then called “biomedical engineering departments”), there were usually several levels of positions and most departments were headed by a clinical engineer with a bachelor’s or advanced degree or someone with many years of experience. Job descriptions and minimum qualifications for department heads often included a bachelor’s degree in biomedical engineering or a preference for a master’s degree in the same field because there were more graduate programs in the field than bachelor’s level.

At the same time, requirements for chief engineers in hospitals often were based upon experience only, with emphasis on hands-on experience with major building systems.

Today, advertisements for positions in clinical engineering are typically for generalist biomedical engineering technicians (BMETs) or specialists in such areas as radiology- and lab-equipment maintenance and repair. There are few positions available for degreed department heads in the clinical engineering field today. Advertisements for chief engineers, on the other hand, have all but disappeared and have been replaced by position postings for “Facilities Director” or “Facilities Manager,” which usually require a minimum of a bachelor’s degree and often a preference for professional registration such as Professional Engineer (PE) in mechanical or electrical engineering. PE is a licensure granted by state consumer affairs departments. It is earned through experience and testing and is intended to reflect minimum competency to practice as a consultant or designer in the specified field of engineering. It is interesting to note that there is no PE category for biomedical or clinical engineering. This fact has contributed to the desire by some to create a certification process for clinical engineering (see Chapter 133). A certification program for clinical engineers is currently administered through the ACCE Healthcare Technology Foundation (see Chapter 130).

Clinical engineers (CEs) might well consider expanding their horizons to a more diverse application of their engineering and management skills. In fact, there is good reason to conclude that the best thing for hospitals and medical centers to do is to install clinical engineers as facilities directors and plant managers. This career path makes sense for many reasons but may seem controversial or even distasteful to many in the clinical engineering profession. This chapter suggests why this should not be so.

First, most in the clinical engineering field know that many who work in facilities operations lack the sensitivity to, and real understanding of, the clinical environment. This is not to brand all facility managers with the same reputation. However, most clinical engineers will recognize the notion that nurses and physicians often call upon clinical engineers to assist in situations that might be the purview of the facilities department but from whom they have had poor response. An even more frequent current example is the perception of users that information technology (IT) departments really do not meet the service and support expectations of clinical professionals. This is because most of the line staff in a clinical engineering department have more education and training than the typical maintenance or plant engineer and have pursued their career because of an interest in working closely with health care providers in a clinical setting. This puts the BMET or clinical engineer on the clinical side of any activity much more than other maintenance or support departments. In fact, most clinical engineering department staff members crave exposure to the clinical environment and staff on a daily basis, while many facilities staff would just as soon wait until patients and clinical staff are gone before they enter an operating room or other patient-care area. BMET’s and clinical engineers sought out their work because they wanted to be in the hospital environment, and their careers are unique to that setting. For the most part, facilities staff might as well be working in an automobile factory, hotel, or high-rise office building. Again, this is not intended as a judgmental statement, but simply a demonstration of the fact that the clinical engineers are uniquely qualified to provide all types of engineering support to the hospital setting.

Second, it is often doctrine to clinical engineers and BMETs that supporting facilities and plant equipment and systems is not nearly as sophisticated and important an activity as supporting medical devices is. One still hears the admonition of clinical engineers not to extend department responsibility to include the maintenance of hospital beds because it could demean the reputation of the members of the clinical engineering department. In the last 20 years, the sophistication of plant equipment and systems, and hospital beds for that matter, has come to match that of much of general medical devices.

Hospital beds now incorporate electronic scales and microprocessor-based controls for air-pump systems, positioning, and safety features. Operating the air conditioning, energy-management systems, fire alarm systems, automatic doors, isolation-room air supply, and many other systems now requires skills and understanding of the same operating systems, networks, and hardware found in patient monitoring and other medical equipment. The skills that are used to test and maintain complex, sophisticated medical device systems are directly applicable to these other systems now found in the physical plant.

Another reason for this strategy is that many hospitals have incorporated, and more will incorporate, the clinical engineering department under the larger umbrella of a facilities department because the latter will probably have a degreed professional in the directorship of the group. This will eliminate the past argument that clinical engineers should not report to a nondegreed chief engineer. If the facilities department is headed by a clinical engineer, the clinical engineering areas will not receive merely secondary support and interest as part of a larger group, but will receive the primary support and understanding that it deserves.

What, then, of the concerns and misgivings of those clinical engineers who might not see this as an attractive career path choice? The clinical engineer may ask a series of questions as listed below. Answers to these questions are also provided along with their rationales.

Question: *Am I really qualified to manage a facilities engineering department?*

Answer: *Almost certainly.*

- Most clinical engineering degrees have the underpinnings of the same undergraduate basic engineering classes and topics as electrical and mechanical engineering.
- Managing budgets, personnel, and business relationships in the hospital environment is the same for both kinds of departments. In fact, the facilities department budget can be ten times the size of the clinical engineering budget, a fact to be revisited in the advantages of making this career move.
- Although clinical engineers might not know the difference between a 500-ton chiller and a cooling tower, with minimal exposure and some reading clinical engineers will recognize the same principals of physics in the operation of air conditioning that they apply to understanding hypothermia devices and other heat-exchange equipment.
- Clinical engineers are already considered technical experts and will be accepted quickly after demonstrating a vocabulary in the facilities area.

Question: *Will I lose the respect of other professionals by involvement with the maintenance of what may be more mundane equipment and systems?*

Answer: *No.*

- This will require managing your own posture and behavior appropriately. From the standpoint of the chief executive officer (CEO), chief operating officer (COO), and chief financial officer (CFO), the importance of your decisions will be greater because you will affect a much larger part of the operating budget and will contribute more to the planning phases of new facilities. By staying involved at some level with the clinical engineering operation, you will not lose your level of respect.
- Your clinical engineering staff probably will be surprised at your level of understanding of plant equipment and operations.

Question: *Will I enjoy my daily activities and efforts as much as I now do?*

Answer: *Yes and perhaps more so.*

- Contributing to the treatment of patients is an interest of most clinical engineers. The more you can influence the mission of the hospital, the more you can contribute. The attention to one medical system may affect one or a few patients—plant operations and systems affect almost everyone in the hospital simultaneously.
- Confronting contingencies is a commonly quoted activity that makes clinical engineering an exciting endeavor. The number of contingencies in a facilities operation will include all of those that you now encounter, plus many, many more, including power failures, communications failures, and water outages.

Question: *What are the advantages and disadvantages of this career change?*

Answer: *See below.*

Advantages:

- The average salary for a clinical engineering director in 2001 was \$60,200, while the average salary for a facilities director in 2001 was \$69,700 (Baker, 2002).
- If the clinical engineering operating budget is a portion of an overall facilities budget under your control, your ability to provide adequate funding for the clinical engineering activities is much greater.

Disadvantages:

- The time requirements will be greater. There will be more committee memberships and project management. Clinical engineering activities will be reduced to less than half of your personal effort.
- Mistakes in the management of life safety and other systems can put your hospital on the front page, and you out the door.

It may be that the traditional position of clinical engineer or clinical engineering director will remain in some hospitals and medical centers, but in a recent survey (Cohen, 2002) responding clinical engineers who were employed in hospitals reported their median age to be 45 to 50 years. In the same survey, younger median ages were reported only for those employed in nonmedical industries or for students. Older median ages were reported for CEs in private practice or consulting. If this survey is truly representative, it would appear that there are few clinical engineering positions in hospitals occupied by a new generation.

Section II

Worldwide Clinical Engineering Practice

Enrico Nunziata

Health Care Technology Management Consultant
Torino, Italy

Health is an issue of concern for all residents of this planet. No country has the solution for addressing the health care needs of all, since each country, region, and locality has its own particular needs, problems, and resources. Health care technology being applied increasingly in an attempt to address health problems has resulted in wonderful successes and dismal failures. "In 50 years \$1 Trillion in aid to poor countries ... failed spectacularly to improve the lot of its intended beneficiaries." (*The Economist* June 26, 1999, p 24). Wealth does not produce immunity to failure, however, as the Institute of Medicine in the United States showed in its report *To Err Is Human*, in which it was revealed that "... at least 44,000 American die each year as a result of medical errors" and that "...the number may be as high as 98,000." Clinical engineers (CEs) bring sound skills and experiences to bear as they strive to more effectively manage the utilization of this technology. Across the globe, the basic principles of clinical engineering can be applied to special situations and particular circumstances.

Clinical engineering is a discipline that is taught, studied and applied throughout the world. National organizations of clinical engineers are found in Mexico, Australia, South Africa, and Italy to name just a few. The American College of Clinical Engineering (ACCE) membership list includes clinical engineers from Albania, Pakistan, Jordan, Poland, India, and many more. These organizations not only are concerned with the local practice of the profession but they also typically take a global view as they realize that information exchange is ultimately beneficial to all. The ACCE, for example, through its International Committee promotes such activities at the Advanced Clinical Engineering Workshop (ACEW), where international faculty present advanced concepts of clinical engineering and health technology management to nations that are intent on improving their health care infrastructure such as China, Russia, Lithuania, Ecuador, Nepal, and Mexico. Information exchange through publications such as *ACCE News* has brought to the world reports of clinical engineering activities in Mozambique, Kyrgyzstan, Mongolia, Namibia, Vanuatu, South Africa, Nepal, and even the United States. This author is editor of the column *CE Around the Globe*, a regular feature of *ACCE News* that describes CE program experience primarily in developing countries.

The International Federation for Medical and Biological Engineering (IFMBE), through its Clinical Engineering Division, has promoted clinical engineering activities among member nations and has sponsored international clinical engineering conferences in France, Italy, and Germany. This Handbook's Editor-in-Chief confided to this author that his participation in these forums and the encouragement, suggestions and advice received from colleagues in attendance from around the world inspired him to assemble papers on all the diverse aspects of clinical engineering under one umbrella text, i.e., this handbook, which would serve as a

comprehensive information resource and an educational vehicle for all members of the health technology community and for all aspiring practitioners of clinical engineering.

The Engineering in Medicine and Biology Society of the Institute of Electrical and Electronics Engineers has found a resurgence of interest in clinical engineering and incorporates clinical engineering tracts in its annual international conference. The World Congress on Medical Physics and Biomedical Engineering brings together clinical engineers from around the world. It was on such an occasion in Texas in 1989 that a small group of CEs planted the seed that grew and flowered into the ACCE through hard work and dedication of its members and from the encouragement of the international community. For decades, the IFMBE, the World Health Organization, the Pan American Health Organization, the European Union and nongovernmental organizations such as Project Hope, FINNDA, GTZ, and FAKT have promoted international clinical engineering research and development programs. The contributions have positively affected the development of clinical engineering in many of the countries whose CE practices are presented herein.

This handbook addresses all the issues of which the clinical engineer and, to some extent, all health professionals should be cognizant. By dedicating an entire section on worldwide clinical engineering practice, the editor-in-chief is emphasizing that there is a great deal to be learned from the problems being faced and the solutions being developed everywhere that the clinical engineering profession is practiced.

In this section of the handbook, starting with a World Clinical Engineering Survey (Glouhova and Pallikarakis), the common threads of clinical engineering practice around the world are revealed as well as the sharp differences in such matters as space allocation, staffing, training courses, and medical device inventories. The authors of the following chapters present in-depth perspectives of the origin, development, implementation and expectations of clinical engineering in their respective countries. The countries included are the United Kingdom (Meldrum), Canada (Gentles), Estonia (Aid and Golubjatnikov), Germany (Dammann), Brazil (Brito), Colombia (Gutiérrez), Ecuador (Gomez), Mexico (Velásquez), Paraguay (Galvan), Peru (Vilchahuan and Brandán), Venezuela (Silva and Lara-Estrella), Japan (Kanai), and Mozambique (Nunziata and Sumalgy), and countries in the Middle East (Al-Fadel). This handbook's international perspective on clinical engineering is not limited to this section, however. The reader also can find examples of clinical engineering practice in other chapters throughout the handbook. Areas of clinical engineering practice, including health care technology management, safety, education and training, medical device manufacture, facilities, standards, and certification, are written by CEs from Australia, Brazil, Cameroon, Canada, Costa Rica, Germany, Greece, Finland, Hungary, India, Japan, South Africa, Sweden, and Switzerland.

World Clinical Engineering Survey

Mariana Glouhova
Clinical Engineering Consultant
Sofia, Bulgaria

Nicolas Pallikarakis
Department of Medical Physics
University of Patras
Patras, Greece

Cost-effective management of biomedical technology within the health care systems is vital to the improvement of health care outcomes. Clinical engineering departments (CEDs) have been created in response to this need. The first international survey was conducted in 1988 (Frize, 1990a; Frize, 1990b), to study the degree of involvement of these departments in equipment management. This study, which included the same participants, was followed by a second one three years later that revealed only minor changes in the majority of the factors affecting the development of the clinical engineering field, except for the workload indicators, i.e., the number of devices and equipment value supported by the CEDs (Bronzino, 1992). Over the coming years, their role, organization and responsibilities have increased and have evolved because of the health care reforms occurring in nearly every country. In order to map the current situation in the field—the changes and the trends in the profession—a world clinical engineering survey has been conducted between 1998 and 2000. The results from this survey are presented and discussed here.

The Survey

This study was performed by launching a survey, in two successive stages, using two structured questionnaires. The two stages of the survey aimed, respectively, to achieve the following: (1) to map the current situation in the field of clinical engineering in the different countries; and (2) to identify common practices and trends.

The first questionnaire intended to register the structure, personnel, responsibilities, and resources of the departments in different countries. It was distributed to more than 1000 hospitals all over the world. The questionnaire was intentionally short and easy to answer, within 20 minutes. It was authored in English and was translated into French, German, Greek, Hungarian, and Japanese.

The second questionnaire had the objective of investigating trends in current practices and addressed selectively only those departments—genitified from the first phase—at well established clinical engineering services. It was authored in English. The estimated time required for completing it was about 30 minutes.

Both questionnaire forms were composed with the use of Pinpoint™ software package. Neither one requested confidential information. Prior to mailing, they were peer-reviewed by a small number of experts from the Clinical Engineering Division of the International Federation of Medical and Biological Engineering (IFMBE). The first questionnaire was distributed by both regular mail and e-mail. The second was mainly sent via the Internet, starting six months after the beginning of the survey.

In total, 178 valid responses were received to the first questionnaire (Glouhova et al, 2000). They were grouped in six regions as follows: North America (NA), incorporating the U.S. and Canada; Nordic countries (NC), including Norway, Sweden, Finland, Iceland, and Denmark; Western Europe (WE), consisting of Germany, the Netherlands, and the UK; Southern Europe (SE), involving Italy, Greece, Spain, and Cyprus; Australia (AUS), and Latin America (LA), comprising Argentina, Brazil, Cuba, and Mexico. The samples collected from Eastern European countries, Asia, and Africa were considered inadequate and therefore was excluded from the present analysis. Table 15-1 shows the level of responses for each region. A range of hospital sizes from about 100 to more than 1500 beds was obtained. Most of those surveyed were teaching institutions. The majority of responses came from departments that exist as separate units. The samples from Southern Europe and Latin America include only small (up to 500 beds) and medium sized (5001-1000 beds) hospitals, while the samples from all other regions include large (more than 1000 beds) hospitals as well.

The second questionnaire yielded 82 responses out of 143 sent, which equates to about a 57% response rate. They were grouped according to the first questionnaire scheme in six groups (see Table 15-1). The sample collected from Western and Southern Europe was

too small and was excluded from the analysis. Consequently, only the responses from North America, the Nordic countries, Australia, and Latin America were further analyzed. The sample is too small to allow definite conclusions, but the obtained data reveal interesting trends.

Results from the First Stage

Structure

Clinical engineering has a long tradition in North America, the Nordic countries and Australia. Most of the reporting departments had been functioning for more than 30 years. In Western and Southern Europe the majority of departments responding were established in the late 1970s and early 1980s, whereas in Latin America, in the mid-1980s. In the few cases when answers came from hospitals where clinical engineering services function as part of another department, these departments were found to be plant operation, facility management, or engineering services in North America; technical department, medical physics or medical physics, and bioengineering in Australia; clinical physics or technical service in Europe; and engineering or maintenance department in Latin America. Their reporting authorities vary greatly in different countries. Some departments report to the hospital administration, but alternatively may be administrated by the director of engineering, plant or materials management, or the medical director.

Personnel

The educational level of engineers and biomedical equipment technicians (BMETs) in the departments varies considerably. Figure 15-1 represents the skill mix in the departments per region. Table 15-2 shows the variation in the skills per region. It is a general trend in all regions that CEDs consist predominantly of BMETs. However, in some departments in the Nordic countries and Latin America, the number of engineers is sometimes equal to, or higher than, the number of BMETs. CEDs in North America and the Nordic countries are large, with many personnel.

Furthermore, it was found that in Latin America all departments have engineers. In some departments in Latin America and in Europe there are no BMETs at all, while in all other areas there are departments without engineers but not without BMETs. In a number of hospitals, there are also medical physicists within the CEDs. In Europe generally, and especially in the Nordic countries, many departments have engineers holding a Ph.D. In Australia and Latin America, clinical engineers are predominantly at the B.Sc. level, while in North America there is an equal distribution of B.Sc. and M.Sc. graduates.

The educational background of the BMETs was further analyzed and compared to the previous survey in Figures 15-2 and 15-3. A clear trend toward longer educational programs for BMETs is noted. The survey indicates that this is predominantly true for the three- and four-year technical education following high school. This is also seen in Figure 15-4, where the educational backgrounds for all regions are studied. Nevertheless, there are BMETs with B.Sc. degrees and some in the U.S. and in Western Europe even hold M.Sc. degrees.

Figure 15-5 shows the number of technicians per engineer per region. In Australia and in North America the number of technicians per engineer is quite high, i.e., 8 and 7, respectively. This ratio drops to 3 in Western and Southern Europe, while in Latin America data show that on average the number of engineers equals the number of technicians.

Table 15-3 summarizes data on age and experience of engineers and BMETs. Clinical engineers appear to be older and with more years of clinical experience, on the average, as compared to BMETs. The situation is different only in Latin America. Therefore, this table reflects a younger profession of clinical engineering in Southern Europe and Latin America.

Table 15-1 Level of responses per region

Q2 Returned	38	9	8	3	10	11	3	82

Figure 15-1 Skill mix in the departments per region.

Although certification for clinical engineers is required only in Iceland, Norway, the Netherlands, Cuba, and the UK (from October 2000), 22% of the reporting engineers are certified in North America, 23% in Australia, 37% in the Nordic countries, 22% in Latin America, 30% in Western Europe, and 35% in Southern Europe. From the responses, it appears that certification for BMETs is required only in Cuba. Nevertheless, 18% of BMETs in North America, 10% in Australia, 13% in the Nordic countries, 19% in Western Europe, and 29% in Southern Europe are certified and hold licenses.

Training and continuous professional development of clinical engineering personnel appear to be common practice in most regions, with the exception of Latin America. The highest frequency of training courses, attended by CED personnel, is in the Nordic countries, where engineers and BMETs attend a course on an average of every 6 months. In North America and Western Europe, the technical personnel take training once or twice per year. In Southern Europe, the majority take courses once per year, while in Australia they do so once or twice every two years. Few departments in North America and Southern Europe reported no training at all. This is also the situation reported by the majority of the departments in Latin America.

Responsibilities

The number of devices and the equipment value supported per full-time equivalent employee (FTE) are shown in Figures 15-6 and 15-7, respectively. Technical personnel in Australia support the largest number of devices, followed by Western Europe and North America. In the first four regions, FTE support between 550 and 600 devices. In the Nordic countries and North America, however, the highest equipment value supported per FTE is found. The highest numbers of devices supported per hospital bed are observed in North America, the Nordic countries, and Australia (Figure 15-8).

Generally, CEDs in small hospitals support medical devices of lower value and of smaller number. Although there are some exceptions, hospital size has always been considered to be directly correlated with the number of devices and equipment value supported by the CED, which is confirmed with the present survey as well. In the majority medium-sized hospitals in North America and the Nordic countries, as well as in the large hospitals in all regions, CEDs support more than 4000 devices, representing more than \$20 million in equipment value. In some large hospitals, CEDs support even more than 10000 devices. More than half of the large hospitals in North America, the Nordic countries, and Western Europe support equipment valued at more than \$40 million. Therefore, in terms of absolute number of devices and equipment value supported by the CEDs, a remarkable increase is observed since the previous survey. However, it is important to note that the technology base in the hospitals in many cases includes equipment not supported by the CEDs. Table 15-4 summarizes data on this, for hospitals with a separate department. In some cases, the departments support all equipment in the hospitals, and on average they have taken this responsibility to quite a high level. In Latin America this process is still not well established.

Table 15-2 Variations in the skills within regions (average number and range per department)

	NA		NC		WE		SE		AUS		LA	
	Av.	R	Av.	R	Av.	R	Av.	R	Av.	R	Av.	R

Figure 15-5 Number of technicians per engineer per region.

Figure 15-6 Number of devices supported by FTE, on average, per region.

Table 15-5 contains the responses regarding the services provided by the departments. Traditional tasks of the departments, such as preventive and corrective maintenance, equipment inventory, acceptance testing, and repurchase consultation (including market survey, development of specifications, evaluation of tenders, and final selection), management of service contracts, and education and training, are performed by a large portion of the departments. However, tasks such as risk management, quality control, and research and development are still not so widely offered. Under "other," departments reported such responsibilities as government activities, project management, administration, consultation, and parts sourcing. An attempt was also made to identify the distribution of tasks between engineers and BMETs. It was found that in the majority of departments, where both engineers and BMETs exist, repurchase consultation (with the four sub stages), management of service contracts, risk management, quality control, education and training, and research and development, are mainly performed by engineers, while preventive and corrective maintenance are predominantly responsibility of BMETs. Equipment inventory and acceptance testing are shared between both professionals. It is important to note however that there is overlapping of roles in performing the tasks to a very high degree.

Resources

Table 15-6 shows the availability of resources other than personnel, which was discussed earlier. The respondents were invited to state the value of their test equipment, spare parts inventory, and budget, as a percentage of the value of biomedical equipment under CED's responsibility. Enormous variations in the reported data are observed. These questions were also not always answered. Therefore, regional analysis and comparisons for these options were not made.

According to the responses, a high percentage of departments in all regions have inadequate staffing levels. Figure 15-9 captures opinions of the respondents on the need for engineers and BMETs. The call for BMETs is quite high in all regions surveyed; moreover, it appears to be higher than the need for engineers. The smallest need of engineers is reported in North America and Western Europe.

Figure 15-10 shows opinions on adequacy of test equipment, spare parts, and space allocation. A level of test equipment, which amounts to at least 1% of the equipment value supported, seems to be adequate for the majority of respondents. It appears, as well, that the same level of at least 1% provides a good basis on which to build spare parts inventory. The value of biomedical equipment under CED management has increased appreciably since the last survey. This percentage reflects as well the significant increase of the value of test equipment and spare parts inventory.

A space allocation of at least 20 square meters per person is considered necessary for departments. The trend from the previous survey of more generous space allocations in the Nordic countries is also seen in the present survey, where 75% of the respondents report having more than 20 square meters per person, followed by 72% in Australia. Departments in Latin America are the least spacious with 94%, with less than 15 square meters per person; the majority are not satisfied with the situation.

Managerial issues

More than 70% of the departments in North America, Australia, and the Nordic countries have implemented quality assurance programs, while the percentages for Western Europe, Latin America and Southern Europe are much smaller, i.e., 43%, 38%, and 29%, respectively.

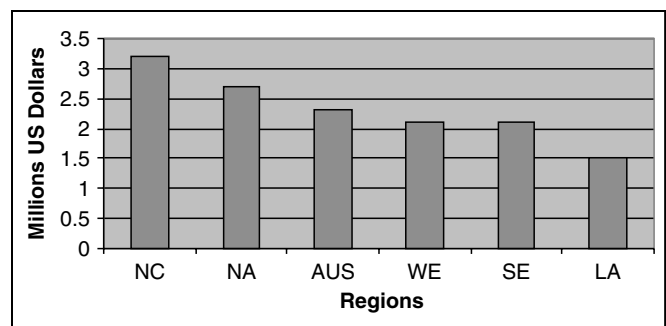

Figure 15-7 Equipment value supported by FTE, on average, per region.

Figure 15-8 Number of devices supported per bed.

tively. This shows a significant increase for all regions compared with the previous survey. The use of a productivity index as a measure of staff performance was recorded in 56% of respondents from North America, 69% from Australia, 45% from the Nordic countries, 26% from Western Europe and just 14% from Southern Europe. In Latin America, the majority of departments use a productivity index (56%), but few have quality assurance programs. Comparison with the previous survey shows an increase in departments evaluating staff productivity using a productivity index. This has been facilitated by computerized systems for equipment management as more than 90% of the departments in all regions reported their use, with this figure being 69% for Latin America.

Space allocation	1.5-77.7 m ² /person	20.9 m ² /person

Results from the Second Stage

Equipment Inventory

All responding hospitals from North America, the Nordic countries, and Australia use a software package for equipment management, which in the majority of the cases is a commercially available product. This facilitates the support for up-to-date inventory and the availability of complete individual files for each item. The situation is different in Latin America, where a relatively small number of hospitals (45%) use software management packages.

The age of life support and therapeutic devices was indicated to be smaller than the age of all other equipment categories in all regions. Hospitals in Latin America, however, are equipped with older equipment, as compared to the other regions.

Preventive and Corrective Maintenance

The majority of the participants maintain written procedures for safety, performance, and calibration checks, while the percentages referring to the availability of written procedures for corrective maintenance (CM) are much lower. Preventive maintenance (PM) procedures and protocols are set in the majority of the cases for each equipment type and are based on manufacturers' requirements, guidelines and standards of associations and institutes, and individual experience, while CM procedures are mainly based on the manufacturers' recommendations. More than 80% of the participants from North America, the Nordic countries, and Australia state that the test equipment used is calibrated according to standards and that it is checked regularly for proper calibration, while this is the case in only about 55% of the participating hospitals from Latin America. More than 80% of the respondents from all regions report that clinical departments and laboratories notify the CED in case of need for repair, even when the contractor is an external service provider. The majority of participating hospitals have a policy requiring authorization for (estimated) expensive repairs before the repair is made, while the replaced parts are only sometimes kept for additional inspection. In rare cases, PM and CM for clinical laboratory and imaging and radiation therapy equipment are the responsibility of CEDs. By contrast, in most cases, PM and CM of patient diagnostic, life support and therapeutic and

**Figure 15-9** Percentage of departments needing additional engineers and BMETs per region.

other biomedical equipment are performed for more than 75% of the devices by the CEDs, as shown in Figure 15-11 and Figure 15-12.

The Survey revealed that the practice of frequently informing the clinics and laboratories about the results of PM checks and CM costs of their equipment is lacking, while PM and CM records are well documented.

Acquisition of Biomedical Equipment

More than 65% of hospitals in all regions have written procedures for the acquisition of biomedical equipment, which are based mainly on guidelines and standards of associations and institutes and on individual experience. In the majority of cases, CEDs are always informed when new equipment is to be purchased. They are consulted in almost all purchases of patient diagnostic, life-support and therapeutic and other biomedical equipment, and, to a much lower degree, for the purchases of clinical laboratory and imaging and radiation-therapy equipment. CEDs in the Nordic countries and Australia have the highest level of involvement in the pre purchase consultations, including clinical laboratory and imaging and radiation therapy equipment. CEDs usually participate in the definition of technical specifications, the evaluation of tenders, and the final selection process. In most cases, the maintenance contracts are negotiated with their active involvement.

Acceptance Testing

Acceptance tests (incoming inspections) of the patient-diagnostic, life-support, and therapeutic and other biomedical equipment are mainly overtaken by the CEDs, while for the clinical laboratory and imaging and radiation therapy equipment the tests are conducted in collaboration with the manufacturers. With the exception of Latin America, the great majority of hospitals in all regions have written procedures for acceptance testing of the incoming equipment, and more than 75% of the new equipment is checked before commissioning. Acceptance tests are sometimes performed after major repairs from outside service providers in North America, the Nordic countries, and Australia. Incoming inspections are well documented.

Management of Contracts

Almost all of the responding hospitals in North America, Australia, and Latin America have established procedures for evaluation of the adequacy of biomedical service contracts, while in Latin America about 80% of the respondents have written procedures on how to proceed when a contract is breached.

Risk Management

Risk management is a well-established service within the CEDs' responsibilities in North America, the Nordic countries, and Australia. Almost all hospitals from these regions responded that they have an internal system for reporting all accidents or equipment-related hazards and that they have a person assigned to address the hazard notifications. Therefore, users are immediately informed in case of hazard notification with a device similar to the one they use, and the hazards are well documented.

Education and Training

More than 70% of the hospitals in all regions have a program for training the medical and nursing staff on the proper and safe use of biomedical equipment. In North America, the Nordic countries, and Australia, the majority of the departments report that they can meet less than 50% of user education and training needs. In Latin America, however, in half of the responding hospitals, the CEDs perform more than 75% of the user's education. There is continuing education for the technical staff as well, which is mainly performed on-the-job or in training courses organized by the manufacturers.

The highest frequency of training courses, attended by CED personnel, is in the Nordic countries—every 6 months; in North America—once or twice per year; and in Australia—once or twice every two years. Few departments in North America reported no training at all, while this is also the situation reported by the majority of the departments in Latin America. However, when inquired if this frequency of training courses is satisfactory, 67% from the participants from the Nordic countries answer positively, with the respective numbers for the other regions—63% for North America, 60% for Australia, and 27% for Latin America.

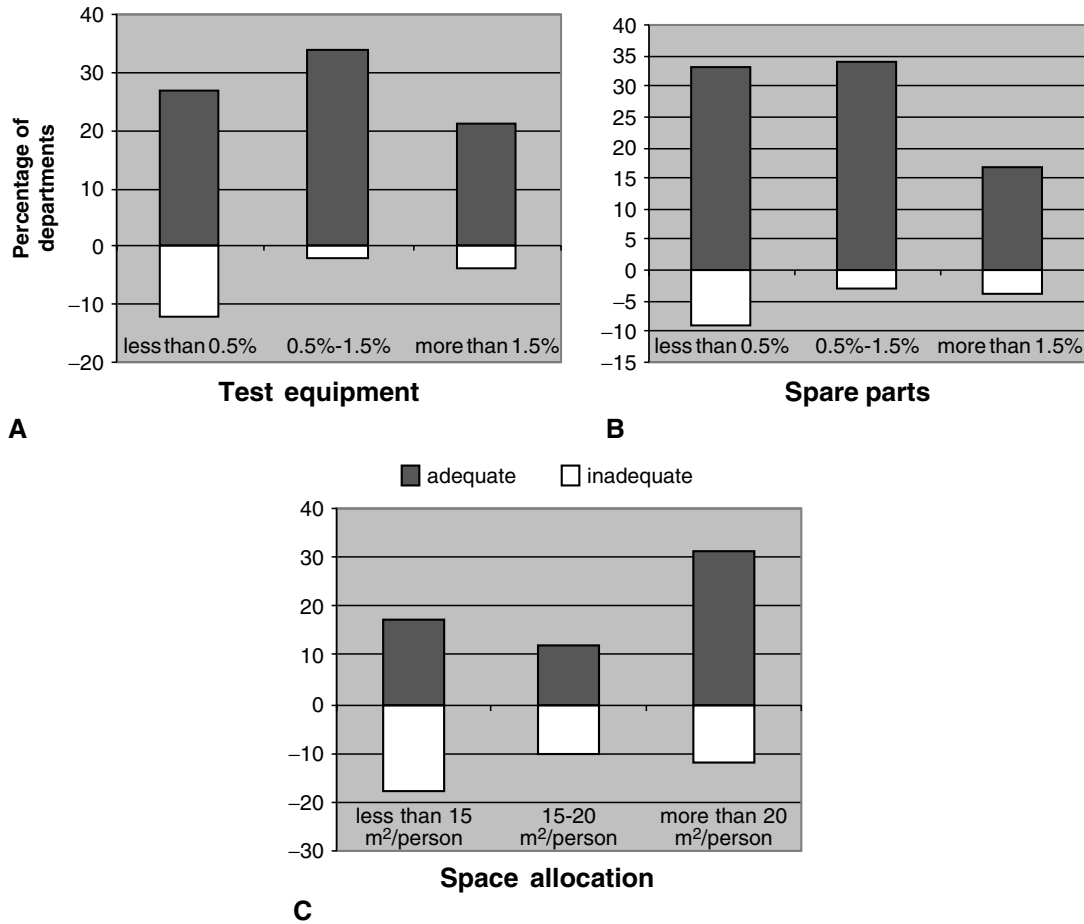

Figure 15-10 Percentage of departments reporting adequacy or inadequacy: (a) test equipment—less than 0.5%, 0.5%-1.5%, more than 1.5%; (b) spare parts—less than 0.5%, 0.5%-1.5%, more than 1.5%; (c) space allocation—less than 15 m²/person, 15–20 m²/person, more than 20 m²/person.

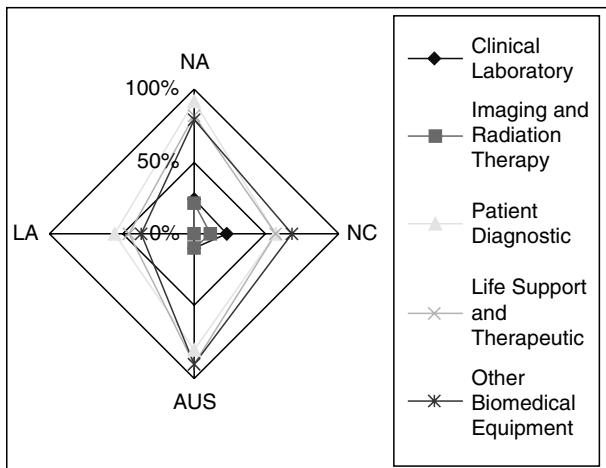

Figure 15-11 PM performed by CEDs to more than 75% of the equipment base.

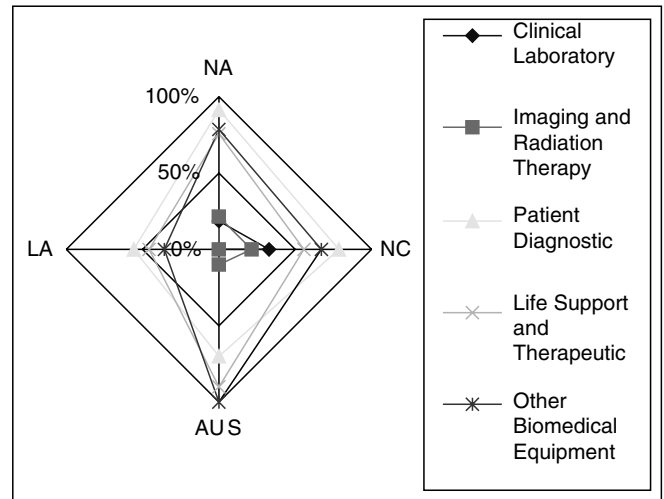

Figure 15-12 CM performed by CEDs to more than 75% of the equipment base.

Research and Development

Research and development (R&D) seems an important activity of the CEDs only in Australia and in the Nordic countries, since 80% and 67%, respectively, of the hospitals from these regions reported that they are involved in such activities. In the Nordic countries, hospitals involved in R&D have more than 5% of their staff assigned to such duties. In Australia, the respective number is about 2%. In some hospitals there is even additional staff hired only for R&D. It is, however, interesting to mention that all hospitals involved in R&D from these regions are teaching institutions.

Quality Assurance

More than 70% of the departments from North America, Australia, and the Nordic countries have implemented quality assurance programs, the majority being in practice for more than 5 years. This shows a significant increase, which comes to justify that the process, which was in its initial phase in 1988, is being more and more implemented and used in practice in 2000.

Finally the survey showed that almost all participating hospitals from North America, the Nordic countries, and Australia have an adequate assess to information related to

current codes and standards and have adequate technical libraries. This is not the case, however, for the majority of hospitals in Latin America.

Discussion and Conclusions

The international survey of clinical engineering departments performed during 1998-2000 came in response to the need to update the available information about clinical engineering worldwide and is the largest ever conducted. The study was designed and performed using a two-step approach. Respectively, to the aims and objectives of each step, two specifically designed questionnaires were distributed by regular mail and e-mail. Questionnaires were sent to hospitals from all continents, and responses were received from all continents.

The received responses produced the largest database that is currently available and revealed that clinical engineering as a profession is better established and recognized today than it was a decade ago. More than 80% of the departments feel that they are well accepted in their institutions. The main problems are lack of highly qualified personnel (because of the lack of quality academic programs); limited funding for technical training to maintain staff competencies for all equipment types; and continuous pressure to reduce costs by increasing department efficiency. However, despite the efforts at harmonization, the management of biomedical technology in hospitals all over the world remains nonuniform, with great variations in terms of structure, personnel, responsibilities, and resources.

In the regions with long tradition like North America, the Nordic countries, and Australia, departments are involved in the maintenance of usually more than 75% of the available equipment value in the hospital. There is also a trend, especially in North America and Australia, for one department to cover the management and maintenance of the equipment of several hospitals, striving in this way for cost-justification and efficiency. In Western and Southern Europe, CEDs maintain, on the average, about two-thirds of the equipment value available. The departments in Latin America are responsible to less than 60% of the equipment value available in the institutions.

In Southern Europe, and especially in Latin America, the profession is still relatively young. However, significant investments are in progress in hospitals in Latin America. Data show that as a general trend, the value of equipment in hospitals has increased drastically over the last ten years, reaching levels of over \$100,000 per hospital bed in North America and the Nordic countries.

Clinical Engineering in the United Kingdom

Stuart J. Meldrum

Director of Medical Physics and Bioengineering
Norfolk and Norwich University Hospital
NHS Trust
Norwich, England

For many years, scientists and engineers in the UK have made major contributions to biomedical engineering. Early emphasis was on research, with more managerial roles emerging only later. Discussion between biomedical and hospital engineers has generally resulted in the most appropriate group in each hospital providing equipment management services. The recent emphasis on risk management and quality of care has been of significant benefit to clinical engineering, with hospitals obliged to establish structures to meet the requirements of clinical governance and controls assurance. A training scheme, introduced in the 1990s, provides theoretical knowledge and practical skills in clinical engineering. Those who successfully complete the training scheme are eligible for professional registration.

Introduction

There has been much discussion about roles and definitions in clinical engineering, but the majority of published work relates to the situation in North America (Goodman, 1989; Bauld, 1991; Shaffer and Shaffer, 1992). In spite of the fact that engineers in the United Kingdom (UK) have a long history of involvement in health care, the term “clinical engineering” has only recently come to be used in the internationally accepted sense of the phrase. The terms “bioengineering,” “biomedical engineering,” and even “medical engineering” are more commonly used in UK hospitals to describe the range of services considered to be the domain of clinical engineering (Webster and Cook, 1979). In this discussion of clinical engineering in the UK, the term will be used as defined by Schwartz (1984): The application of biomedical engineering knowledge in a health care context.

The late development of the concept of clinical engineering in the UK can be attributed to a number of factors. Initially, engineers entered the field of medicine to work in research and development and only later took on managerial roles. Secondly, biomedical engineering was seen as a scientific, rather than an engineering, discipline, with many of its practitioners working in medical physics departments. For reasons of perceived status, staff preferred to refer to themselves as “medical physicists” rather than “clinical engi-

neers” in spite of the fact that they performed an engineering function. Thirdly, for many years there has been a centralized health care system in the UK that, until recently, showed little awareness of the wider contribution that clinical engineering could make.

Fortunately, with the recent emphasis on the quality of health care, the situation has changed. Clinical engineering is now receiving greater recognition and is seen to be able to contribute more than just equipment maintenance. In recent years, a national training scheme for scientists and engineers in health care has been introduced. Training is provided across a range of subjects from radiation physics to rehabilitation engineering, thus serving to blur the distinction between the roles of medical physicist and clinical engineer.

Early Beginnings

Scientists and engineers in the UK have made a major contribution to the development of biomedical engineering from its earliest days. In 1958, leading scientists and engineers from around the world met in Paris for the first world conference on medical electronics. At that meeting, it was suggested that an international society should be established to serve the needs of the rapidly expanding field of engineering as applied to medicine. The following year, a second international conference was held (again in Paris), at which a decision was taken to form the International Federation for Medical and Biological Engineering (IFMBE). Of the 41 founding members of this organization, three were from the United Kingdom (Mito et al., 1997).

A year later, the world conference was held in London. It served as the catalyst for the formation of a society to serve the needs of biomedical engineering in the UK. Consequently, the Biological Engineering Society (BES) was established in 1960 as a multidisciplinary society, the aim of which was to foster cooperation among engineers, scientists, technologists, and others engaged in the life sciences. Note that the chosen name was “biological engineering” as the society was intended to encompass the application of engineering to biological systems in the widest sense. In subsequent years, many biologists and physiologists played prominent roles in the ‘society’s affairs. In 1963, the BES was one of the first national societies to affiliate with IFMBE.

From its formation, the BES provided a focus for biomedical engineering activity in the UK. This situation continued until 1995, when the BES merged with the society representing medical physicists to create what is now the Institute of Physics and Engineering in Medicine (IPEM). Thus there is now a single professional body representing the interests of physicists and engineers in medicine, providing an opportunity to integrate the education, training and methods of service delivery.

Emphasis on Research

During its early years, biomedical engineering in the UK was seen essentially as an academic discipline. Many of its contributors were employed directly by clinical departments, with the development of new diagnostic and therapeutic techniques as their primary role. Biomedical engineering departments were established in a few of the major teaching hospitals, and while providing a focus for bioengineering activity, they were often dependent on research funding for their continued existence.

By the 1970s, accounts of departmental research activities began to appear in the literature. Roberts has described how the department at King's College Hospital, London, was established in 1967 (Roberts et al., 1971). Research was carried out in collaboration with vascular surgeons, and prominence was given to the development of novel techniques for the measurement of blood flow. Roberts stresses the importance of carrying out such research in a clinical environment, where there is day to day awareness of clinical needs.

Watson has described the origins and early years of the Department of Medical Electronics at St Bartholomew's Hospital (Watson, 1975). Initial funding was provided by the hospital-research board. Within 10 years, groups were working on problems as diverse as blood flow, incontinence, dialysis, speech aids, and radiotelemetry. Watson was one of the first to acknowledge the importance of providing adequate management of equipment and the bearing that this had on the safe delivery of services.

Considering its population, Scotland has always made a disproportionately large contribution to bioengineering activity. This has been attributed to both the academic traditions of the country and to the close relationship between the universities and the providers of health care. Services in Scotland tend to be based on large, regional departments, a structure that has encouraged the development of bioengineering in each of the major centers of population. By the late 1960s, a wide range of bioengineering activity was taking place (Forwell, 1970).

Equipment Maintenance in Hospitals

As already mentioned, the early emphasis in bioengineering was on research. During the 1960s, however, health care became increasingly dependent on technology. By the early 1970s, hospitals were becoming aware of the lack of appropriate arrangements for managing this technology. Around this time, a group was established to address the issue, with membership drawn principally from regional hospital engineering departments. The outcome was a proposal that a network of properly structured groups should be established across the country, with a remit to supervise the management of all medical equipment (DHSS, 1971). It was envisaged that these groups would be located within hospital works departments and that they would provide maintenance services that were largely independent of the equipment manufacturers.

These proposals—principally that the maintenance of medical equipment was the preserve of the hospital engineer—caused some consternation in bioengineering circles (Anon, 1972a; Anon, 1972b). In response, the medical physicists issued a counterproposal suggesting that clinical equipment was so complex that its maintenance required a scientific, rather than a hospital engineering, background (Perry, 1973). The hospital engineers' proposal was never implemented, but did serve to bring the issue of equipment maintenance to the attention of the wider bioengineering community. Ultimately, services were developed and provided by the most appropriate group in each hospital.

Garrett has described the setting-up, funding, and organization of the highly respected department in Bristol (Garrett, 1984). The initial remit was to identify equipment that could be economically and effectively maintained in-house. It was estimated that this could be done at a cost one-third less than that of the external contractors, who were generally the equipment suppliers. No new funding was provided for the project, as the scheme was expected to create its own funding from cancellation of maintenance contracts. The Bristol development was based on the bioengineering group within the medical physics department as it had the necessary range of expertise.

In addition to providing support for the normal range of electromedical equipment, the Bristol group was also responsible for the high-energy accelerators and cobalt machines used in radiation therapy. The high value of this equipment, and the related savings from transferring to in-house maintenance, played a major part in establishing the viability of the service. Unfortunately, few clinical engineering departments are able to benefit from the inclusion of such high-value equipment in their inventories. Garrett also discussed the difficulties of comparing in-house with external costs but concluded that the simple measure of saving the cost of external contractors' travelling time can be of significant benefit to the hospital. Stamp has described the development of the medical equipment management service in Sheffield (Stamp, 1984). There, the service, which is also based on the expertise of the local medical physics department, caters to a number of adjacent health districts, thus providing greater economy of scale.

Guidance Documents

A centrally managed health care system, such as that in the UK, tends to develop in response to guidance published by the Department of Health. Equipment management services are no exception, and over the years a number of guidance documents have been published on what constitutes good practice in medical device management. The first of these, *Health Equipment Information 98*, was published in 1982 in response to a growing awareness that many accidents in hospitals were caused by poor maintenance

and repair (DHSS, 1982). These guidelines provided a comprehensive cradle-to-grave approach to equipment management and were promptly implemented by many hospitals. Guidance was offered under five headings: Procurement, acceptance, maintenance, training, and disposal. Whelpton has described the manner in which these recommendations were implemented across a district-wide service in Nottinghamshire (Whelpton, 1988).

In 1998, the guidance was updated to take account of changes that had occurred in legislation, particularly that relating to CE marking of medical equipment (MDA, 1998). The revised document also acknowledged the increased use of medical devices in patients' homes, and the problems associated with their management and support.

Thus although the components of a clinical engineering service had been in place for a number of years, clinical engineering service has not been referred to as such until recently. There has been relatively little written about the provision of clinical engineering services in UK hospitals, with the work that does exist generally confined to descriptions of how central guidance has been implemented in various centres. While North American authors have frequently written on the economics of health technology management (Furst, 1986; Betts, 1989), this is rarely discussed in papers from the UK. It has been suggested that the anomalies of Health Service accounting are largely to blame, with few clinical engineering departments having sufficient budgetary control to demonstrate the benefits of their services (Charles and Woolley, 1984). In the UK system, large items of equipment are frequently purchased with central funding, with little or no provision to meet revenue costs or end-of-life replacement. Equipment management budgets are often underfunded, and consequently grossly overspent, and equipment runs beyond the end of its economic life.

In the UK today, the clinical engineering function is generally provided by an in-house team. In teaching hospitals and larger, district hospitals, these teams tend to be led by a graduate engineer, while in smaller hospitals the team is led by a biomedical equipment technician. Private hospitals in the UK tend to be small and purchase clinical engineering services from neighboring state hospitals or from private sector maintenance organizations. While a few independent service organizations do exist, they have made little impact on the overall provision of clinical engineering services.

Clinical Engineering Certification

Medical equipment management services developed in the UK with little acknowledgement of the ways in which clinical engineering had developed in North America (Bronzino, 1995). By the mid-1980s, however, members of the BES had become aware of the clinical engineering certification scheme that was being run in the U.S. and decided to introduce a certification scheme of their own. The UK scheme was loosely based on the one that was operating in North America, but no written examination was involved. Applicants were assessed on the basis of a written account of their work experience and an in-depth interview.

The UK clinical engineering certification scheme was never successful, however, as there was always an underlying uncertainty about its aims and objectives. Unlike the U.S., the UK has no separate professional organization representing rehabilitation engineers. The BES certification scheme, therefore, had to accommodate both groups. Engineers working in rehabilitation claimed that they were the only true "clinical" engineers as they were the only ones playing a direct role in patient care. Consequently, the criteria for certification were modified to include the requirement that applicants spend a certain percentage of their time in direct patient contact. The effect of this was to close off certification to many senior members of the profession, who were exclusively involved in administrative and managerial duties. The certification process attracted too few senior members of the profession to ensure its success and was closed in favor of encouraging biomedical engineers to seek registration as professional engineers.

The Changing Health Care Climate

A new discipline, such as clinical engineering, can develop and grow only in a health care system that values the contribution it makes. State-funded health care has been available in the UK since 1948 and was intended to be comprehensive and free at the point of delivery. Over the intervening years, many organizational changes have been made with the aim of providing a more responsive and cost-effective service (Webster, 2000). The early 1990s saw the most fundamental of these changes with the introduction of the concept of the "internal market." Central to these reforms was the purchaser provider split. Health authorities purchased services on behalf of patients, while hospital and community services were split into about 450 independent self-governing trusts. It was envisaged that, by encouraging hospitals to compete with each other, efficiency of care would be improved, and costs forced down. A more financially aware health care system might be expected to recognize the wider contribution that clinical engineering could make, but this was not the case.

The Quality Agenda

It was only during the late 1990s, with the introduction of a quality agenda, that the health care climate became more conducive to the development of clinical engineering. While formal systems for clinical risk management had been commonplace in some countries for many years, it was only during the 1990s that such arrangements became commonplace in the UK (Walshe, 2001). One factor driving this change was the increased tendency toward litigation and the related increase in cost to health care providers. In the mid-1990s, a national clinical negligence scheme was established to help defray the costs for individual hospitals. The scheme involved the introduction of national standards for risk management, including appropriate arrangements for medical equipment. Hospitals are audited against these standards, and they benefit from a reduced premium if certain standards are met. Thus, there now are clear financial benefits to having access to an effective clinical engineering service.

Clinical Governance and Controls Assurance

Despite these developments, which raised the general awareness of risk management, there was no unifying philosophy upon which to build (Secker-Walker and Donaldson, 2001). This was only introduced in 1998, with the publication of the Government's White Paper on the future of the health service (HMSO, 1997). Trust management boards were required to monitor the quality of the care that they provided, with the same rigor as applied to financial matters. In practice, this requirement was met by introducing the concept of "clinical governance."

Contemporaneously with the introduction of clinical governance came the concept of "controls assurance." While clinical governance was intended to improve the quality of care, controls assurance was intended to improve the environment of care (Figure 16-1). Controls assurance is intended to provide evidence that health care providers are doing their reasonable best to manage their affairs in a way that protects patients from harm. Hospitals are required to audit a range of activities, one of which was the management of their medical equipment. Furthermore, a key component of control assurance is the ability to demonstrate that an appropriate delivery framework exists within the organization. Clinical engineering has an obvious part to play in demonstrating that this is the case.

Controls assurance places new emphasis on involving clinical engineers in the more strategic aspects of equipment management. There is also a recommendation that clinical engineers should be more involved in user training. Until controls assurance was introduced, few clinical engineers had been involved in this aspect of medical device management (Fouladinejad and Roberts, 1998). Involvement in user training is also important in demonstrating that clinical engineering departments are more than just repair shops (Frize, 1994).

National Audit Office Report

The profile of clinical engineering was further raised in 1999 with the publication of a report on the management of medical equipment, prepared by the National Audit Office (NAO) (NAO, 1999). One of the reasons why the government commissioned this report was an awareness of the fact that the medical equipment used in the Health Service represented a considerable national asset. Ensuring good practice in maintaining this asset would save the nation large sums of money. The NAO report discussed the role that clinical engineering could play in coordinating manufacturers' service provision and the benefits that would result from providing at least part of the maintenance program using in-house biomedical engineering staff. The other major area covered in the report was that of device safety and the role of clinical engineers in reporting and investigating device-related incidents. The authors of the report also noted the wide differences in service provision that they had encountered across the country. The report suggested that by benchmarking costs and management practices many financial savings and quality improvements would result.

Training and Registration

Basic Training

In the early 1990s, the British government introduced formal training schemes for a number of scientific disciplines working in health care, including medical physicists and clinical engineers. IPEM was duly charged with developing the scope and content of the program. One of the strengths of the scheme is that it is centrally funded, with trainees employed for the duration of the two-year training period. Training is demand-led, with

the number of training places tailored to fit the needs of the various professional groups. Thus, all trainees would expect to find a post somewhere in the country at the end of their training.

All training is carried out in accredited centers that are able to demonstrate that they possess the necessary resources. These are both material resources, such as equipment and books, and human resources, such as staff who have the appropriate seniority and experience. Training centers were initially accredited for a period of three years, but for most centers this has now been extended to five years.

Trainees generally enter the scheme as new graduates in either physics or engineering. During the first two years, emphasis is on the acquisition of basic knowledge and practical skills. Basic knowledge is gained by attending a master's course in an appropriate subject. A list of accredited M.Sc. courses is maintained by IPEM (www.ipem.org.uk). Of the 20 courses currently listed, eight are biased toward biomedical engineering, with the remainder concentrating on medical radiation physics.

Practical skills are gained during hospital placements, when trainees generally opt to study three areas of medical physics or clinical engineering. The range of subjects is shown in Figure 16-2. From the top down, the list starts with subjects that might appeal to a trainee who is interested in medical physics. From the bottom up, the list contains subjects of more interest to the clinical engineer. Presenting the subjects in this way serves to indicate the continuum of subjects in medical physics and clinical engineering, rather than presenting them as separate disciplines. Trainees in clinical engineering will tend to opt for medical electronics and instrumentation, physiological measurement, and possibly information management and technology.

Practical skills are gained during three placements in hospitals, with each subject placement lasting for a period of six months. During this period the trainee is expected to produce a portfolio, describing the work that has been carried out and the manner in which the various competencies have been acquired. In the remaining six months of the two-year training period, trainees study core material such as the structure of the health care system, medical ethics, and relevant legislation. At the end of the two-year training period, trainees undergo an in-depth interview in each of the specialist areas covered. Successful trainees are awarded the Diploma of the Institute of Physics and Engineering in Medicine.

Higher Training

Upon successful completion of training, candidates apply for junior staff posts in hospitals. During basic training, a trainee may choose to study a mix of subjects, including aspects of both radiation physics and clinical engineering. At this point, however, they tend to specialize in one or the other. The first two years in these new posts include further compulsory training, with trainees learning more specialized skills in their chosen field. This is followed by a further two years of supervised responsibility before the trainee can take the examination to become a full-fledged corporate member of IPEM. Upon completion of training, members are expected to follow a balanced program of continuing professional development (CPD). This program requires that a minimum of 50 CPD points are acquired each year, with each point corresponding to one hour of development activity. A record of achievement, which is open to audit, must be maintained.

Engineering Registration

One of the reasons for discontinuing clinical engineering certification in 1998 was that few employers understood its significance, and consequently few posts were advertised with certification as a requirement. When considering the future of certification, IPEM took the view that professional engineering registration was more widely recognized and that it should be the standard to which all engineers aspire.

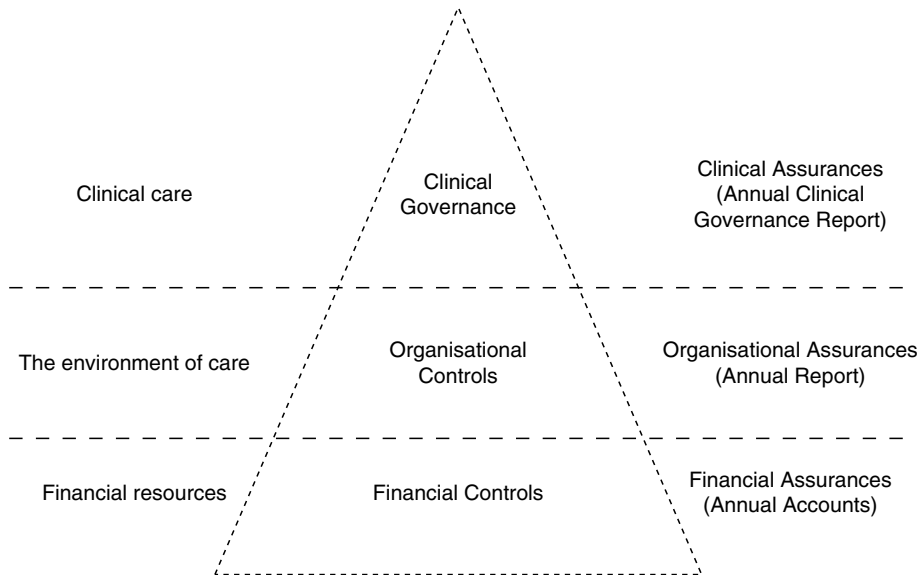

Figure 16-1 Relationship between clinical governance and controls assurance and the various reporting requirements.

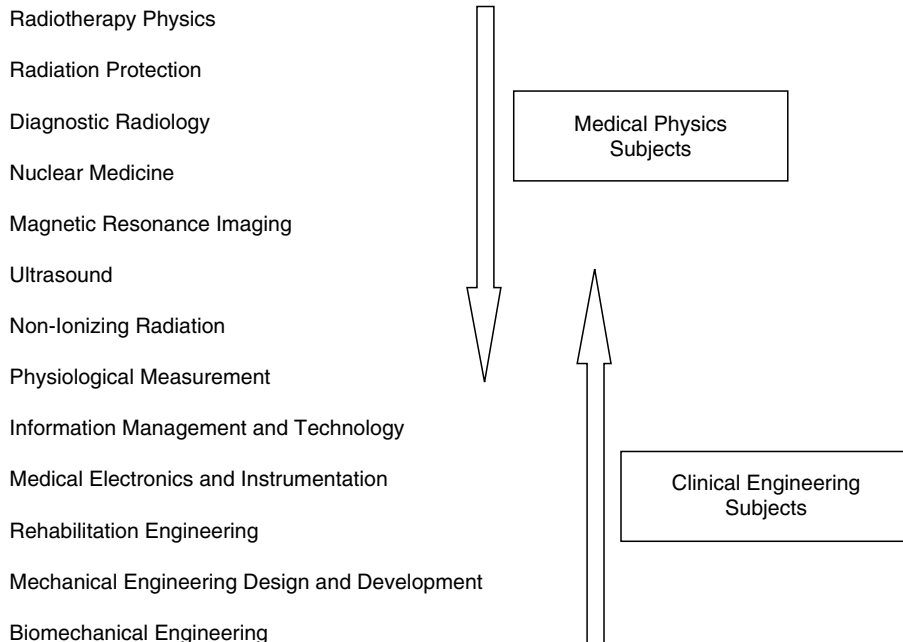

Figure 16-2 Major subject areas in IPPEM training scheme for clinical scientists and engineers.

In the UK, the Engineering Council is charged with maintaining the register of professional engineers, who are referred to as Chartered Engineers and use the designatory letters CEng after their names (www.engc.org). The council does not accept direct applications for registration but relies on one of approximately 35 approved engineering institutions to process applications and to uphold its standards. IPPEM, as a nominating body, is able to accredit courses and to approve individual development programs and IPPEM's corporate-membership interview can also serve as the professional-review interview for registration. Thus clinical engineers who pass through the IPPEM training scheme can progress to full professional registration with a minimum of inconvenience. Table 16-1 describes the structured training for clinical engineers leading to professional engineering registration.

State Registration

In 2000, the profession of "clinical scientist," which includes the practice of clinical engineering, was formally recognized with the establishment of a registration board under the Professions Supplementary to Medicine Act (1960). The board, as a statutory body, is the means by which the state ensures that the profession is formally regulated. The board has three main functions: To maintain a register of clinical scientists; to regulate the education and training leading to eligibility for registration; and to cancel registration in cases of infamous conduct. State registration has one aim: The protection of the public. All clinical scientists and clinical engineers working in the UK health service must now be state registered, and loss of registration will mean that the person may no longer work in the public sector. Further details are available from the registration Council (www.cpsm.org.uk).

Conclusions

Since its academic beginnings, clinical engineering has now established its own professional identity. Recent guidance documents from the department of health have stressed the importance of the contribution that clinical engineering can make to health care, particularly in areas of quality assurance and risk management. Recognition of clinical engineering in the basic training scheme, the introduction of state registration for clinical engineers, and a more concise route to professional engineering registration have helped to create a greater sense of identity.

Table 16-1 Structured training for clinical engineers leading to professional engineering registration.

Activity	Duration	Award
Undergraduate course in physics or engineering	3 years	First degree
Basic training in 3 areas of medical physics or clinical engineering	2 years	Higher degree plus IPPEM Diploma
Higher degree in medical physics or clinical engineering		State registration
Higher training	2 years plus 2 years responsible experience	Corporate Membership of IPPEM Registration as Chartered Engineer

Clinical Engineering in Canada

William M. Gentles

BT Technology Consulting
Toronto, Ontario, Canada

Canada's health care system, its geography, and its political landscape all have had an influence on the way that clinical engineering has evolved as a profession in this country. Like many other countries, Canada has seen dramatic changes in health and health care over the past 50 years. The Canadian health care system is distinguished by the fact that it is funded by tax revenues and that it is free for all residents of Canada. These traits lead to efficiencies, but they also mean that the system is subject to political pressures.

The Canada Health Act (CHA, 2001) is Canada's federal health insurance legislation. The aim of the national health insurance program is to ensure that all residents of Canada have reasonable access to medically necessary insured services, without direct charges. The legislation only permits the establishment of private, for-profit hospitals to provide services that are not defined as medically necessary. The legislation does not cover dental care, and the list of services that are defined as medically necessary is constantly evolving.

In the year 2000, total health expenditures in Canada were approximately \$2000 per capita. Health expenditures accounted for 9.3% of Canada's gross domestic product.

Although the Federal government sets standards for health care, the provincial governments have the responsibility to manage and to pay for health care. Tax dollars collected by the federal government are handed over to the provinces and territories according to a complicated formula. In each of the ten provinces and four territories, health care is managed in a slightly different way. In the last decade, most provinces have made major structural changes in their health care systems. The number of hospitals and hospital beds in Canada is in a state of constant flux as provincial and territorial governments attempt various schemes to manage costs, such as regionalization and restructuring. Between 1995 and 2000, approximately 275 acute care hospitals were closed, merged, or converted to other types of care facilities. This consolidation was a natural consequence of the trends to shorter hospital stays, increased day surgery, increased number of minimally invasive procedures, and increased use of home care.

Canada's single-payer health insurance system results in hospitals that tend to have high occupancy rates, with equipment that is heavily used. Clinical engineering departments have been under pressure to control costs and, in many cases, to downsize as the health care system has been subjected to repeated funding constraints by governments.

Canada is a large country, with a relatively small population. Most of the population is concentrated along the Canada-U.S. border. Health services are spread thinly in the northern regions, and clinical engineering services to support health care in northern regions are often based in larger centers to the south. New technologies, collectively known as "telehealth," are beginning to offer innovative ways to deliver health care services over large distances. Examples are teleradiology and telemonitoring of home-care patients.

Clinical Engineering Departmental Funding Sources and Economic Pressures

For the most part, Canadian clinical engineering departments are funded from hospital global budgets. They must compete with other services within the organization for limited funds. Funding levels are inconsistent, as no national workload measurement system exists for clinical engineering in Canada. One common trend is for departments to grow over time as they prove their value to the organization, and then to get cut back when there is a change in leadership in the department. Although many departments are able to track and to report on the cost of providing services, most are globally funded for their core services and do not charge customers directly for their services.

Many hospitals in Canada have recently begun to reinvest large sums in capital equipment, resulting in an increase in the workload for the clinical engineering service. In some cases, the clinical engineering service has been successful in tying an increase in capital-equipment inventories to an increase in operating funds for the department. At Sunnybrook & Women's College Health Science Centre, for example, the biomedical engineering department receives an increase in its operating budget of 5% of purchase cost of new equipment related to program expansions. Of this amount,

approximately 80% is allocated to salaries, and 20% to parts and supplies to support the expansion.

Typical Department Programs and Services

During the development of the Clinical Engineering Standards of Practice for Canada (See Chapter 123), a consensus emerged as to what the basic programs and services that any clinical engineering service in Canada should provide. The following list is based on these Standards of Practice.

Medical Device Technology Management

- Device tracking and inventory
- Acquisition
- Unscheduled maintenance

Scheduled Maintenance Technology Assessment and Planning

- Planning and pre-purchase evaluation
- Assessments of safety, efficacy, and cost-effectiveness
- Long-range device planning

Risk Management

- Reuse policy development
- Managing hazard alerts and recalls from Health Canada, FDA, ECRI, and vendors
- Incident investigation.
- Education of device users
- Modification of devices

Management Models Example of a Nonregionalized Service

Sunnybrook & Women's College Health Sciences Centre (SWCHSC) in Toronto is an amalgamation of three founding hospitals. The founding hospitals were Sunnybrook Health Science Centre, Women's College Hospital, and the Orthopaedic and Arthritic Hospital. These hospitals amalgamated under a government directive in 1998. There was a comprehensive clinical engineering service led by a director, Bill Gentles, in the largest of the three hospitals, Sunnybrook, and a smaller service at Women's College. The Orthopaedic & Arthritic Hospital relied on outside vendors for clinical engineering services (see Figure 17-1).

After the amalgamation, the Department of Biomedical Engineering was one of the first departments to be consolidated. There were no staffing changes—the manager at Women's College simply reported to a new person. The department was given a mandate to consolidate services and to provide service to the Orthopaedic & Arthritic campus. The amalgamated organization has approximately 1200 beds, with trauma, cardiac surgery, and neonatal intensive care generating the majority of the work load for the biomedical engineering department.

The department had developed a growing range of nontraditional services at the Sunnybrook site. These included PC hardware repair, maintenance insurance, a central equipment pool for infusion pumps and other small equipment, and surgical-instrument repairs. These services were funded on a chargeback basis, and other departments were charged by the mechanism of "cost transfers" for services provided.

Total staff in the department is 19 full-time equivalents (FTEs), of whom five are funded by cost-recovery programs, and the remainder by the global budget of SWCHSC. Technologies supported by the department include patient care medical devices, personal computers, lasers, surgical instruments, and some laboratory equipment. Technologies not supported include medical imaging, large lab analyzers, and

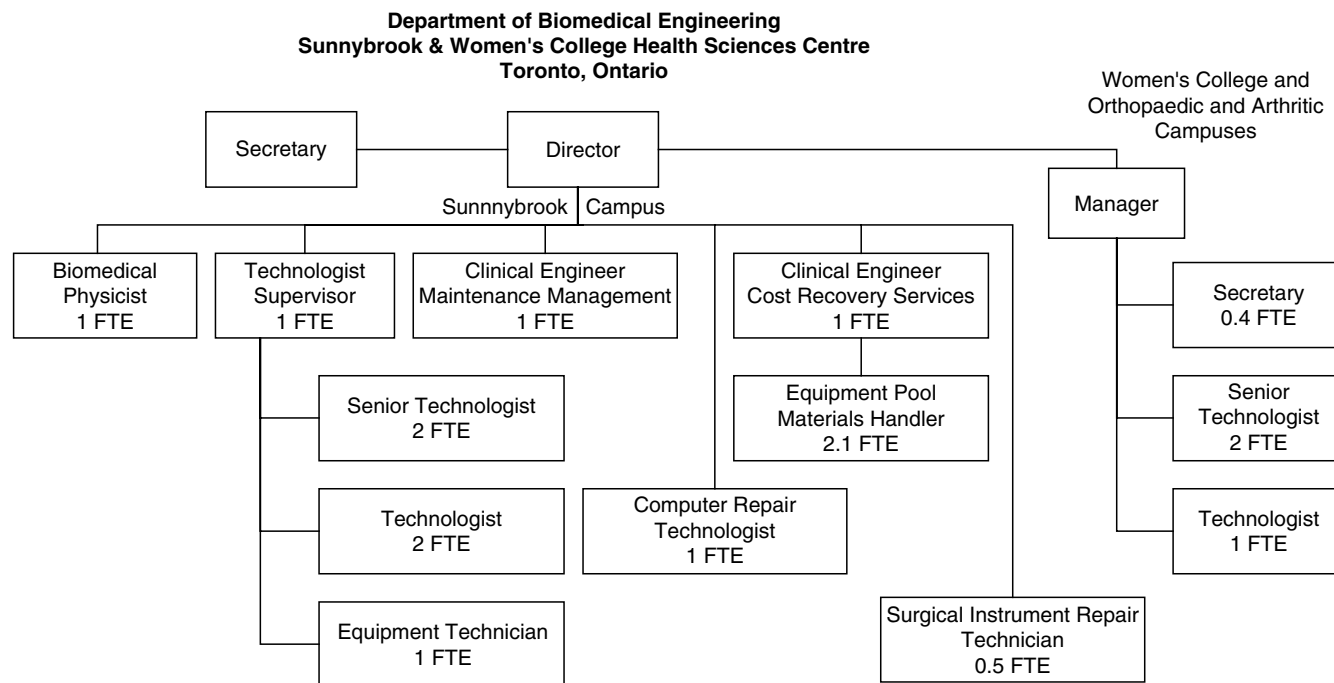

Figure 17-1 Department of Biomedical Engineering Sunnybrook and Women's College Health Sciences Centre.

renal dialysis. As of March 30, 2001, the director reported to the vice president of clinical support services. This reporting relationship has subsequently changed with the retirement of the director.

Regional Services

As of the year 2000, most provinces and territories (with the exceptions being the province of Ontario and the territory of Nunavut) have reorganized hospitals into regional groups, usually, with a single governing board for each region. The clinical engineering services in these regional groups of hospitals tend to thrive as they demonstrate their cost-savings potential.

Prior to this trend in the 1990s, clinical engineering departments were, most often, stand-alone services providing service to only one hospital. Smaller hospitals (i.e., fewer than 200 beds) would typically outsource clinical engineering services to vendors or third-party service providers.

With the trend toward regionalization, clinical engineering departments in larger hospitals found themselves responsible for providing service to a number of smaller institutions within their geographical area. In many cases, they evolved into large, regional groups providing service over broad areas, with funding coming from the regionalized hospital group. In other cases, a large department servicing a single site took on the responsibility for managing groups of technicians in smaller hospitals within the same region, where the technicians were paid by the individual hospitals. In general, the trend to regionalization has led to the growth of in-house services at the expense of for-profit service groups.

The following Organizational Chart (Figure 17-2) shows the staffing levels and management structure for a regional service based in Edmonton Alberta. This service supports six acute-care hospitals. The number of staff in this service totals 63 FTE's, of which about 50 are funded by the region, and the remainder are funded by individual hospitals. Nontraditional services include a central equipment pool, a clinical system IT coordinator, and a maintenance management specialist. Technologies supported by the service include patient care medical devices, lasers, renal dialysis, and some laboratory equipment. Technologies not supported include medical imaging and large lab analyzers. The regional manager reports to the director of equipment management in the capital equipment planning portfolio.

Outsourcing and Third-Party Services

Although there is nothing in the Canada Health Act that prohibits the outsourcing of support services by hospitals, the penetration of for-profit clinical engineering service groups in Canada has been limited. The landscape of third-party service providers is in a state of flux in Canada, as it is in other countries. Mergers and acquisitions are always occurring. The number of independent groups providing for-profit clinical engineering services decreased during the 1990's. GE Medical (Canada) acquired one of the larger independent Canadian groups, formerly known as BESSI, as part of the GE strategy to offer a full range of multivendor services. ServiceMaster Canada acquired a group formerly known as ESNA Biomedical. Consequently, in 2001, there was only one large independent service organization offering clinical engineering services in the country—ServiceMaster Canada. Their penetration of the Canadian market has been limited.

GE Medical has had some success in marketing its multivendor service in Canada. Other large vendors of imaging equipment such as Siemens and Philips do not offer multivendor service in Canada.

Sources of Trained Staff

Managers in clinical engineering commonly come from the clinical engineering program at the University of Toronto Institute of Biomaterials and Biomedical Engineering (<http://www.utoronto.ca/IBBME/>), which offers a Master of Health Science degree that incorporates three hospital internships. Technologists come from a number of postsecondary programs that offer two- or three-year programs in electronics engineering technology with a biomedical focus: British Columbia Institute of Technology (<http://www.bcit.ca>), Northern Alberta Institute of Technology (<http://www.nait.ab.ca/>), Fanshawe College in Ontario (<http://www.fanshawec.on.ca/>), and College of the North Atlantic (<http://www.northatlantic.nf.ca>) in Newfoundland.

New Program or Service Initiatives

One growing trend in many departments is to develop enhancements to the service that are funded by charging the end-users directly. These services are run on a business model and compete with outside services that the hospital is already purchasing. If the in-house service is cheaper and of a higher quality, it is usually successful in selling the concept to customers and stakeholders. Examples of such services are computer repairs, medical imaging service, maintenance insurance, and surgical instrument repairs.

Departments are also looking outside their organizations for sources of revenue. In Ontario, the ambulance services are organized around Base Hospitals, and it is common practice for the Biomedical Engineering group in the Base Hospital to have a contract to maintain the defibrillators and other life-support equipment for a fleet of ambulances. Other initiatives include providing contracted services for clinics and labs that are not affiliated with the hospital.

With the growth of complex technologies used in the operating room and intensive care units, there has been a growth in the number of equipment technicians whose function is to operate these complex devices during routine procedures. In many organizations, the clinical engineering service is seen as the logical home for these technicians. In the past, the participation of clinical engineering staff in routine clinical procedures has been avoided by many clinical engineering groups because of staffing limitations. There appears to be an opportunity for growth in this area that many clinical engineering services in Canada have actively pursued.

With the move toward a comprehensive electronic patient record (EPR), clinical engineering services are working more and more closely with information technology (IT) services. There is growing involvement of the IT service in the specification of patient-monitoring equipment that will meet the needs of the EPR. In the case of the Regional Clinical Engineering Service in Edmonton, it can be seen on the organization chart that a distinct position has been created, called Clinical System IT Coordinator. The need for clinical engineering services to have staff trained in computer networking is widely recognized. Positions have been created in many clinical engineering groups to meet this need.

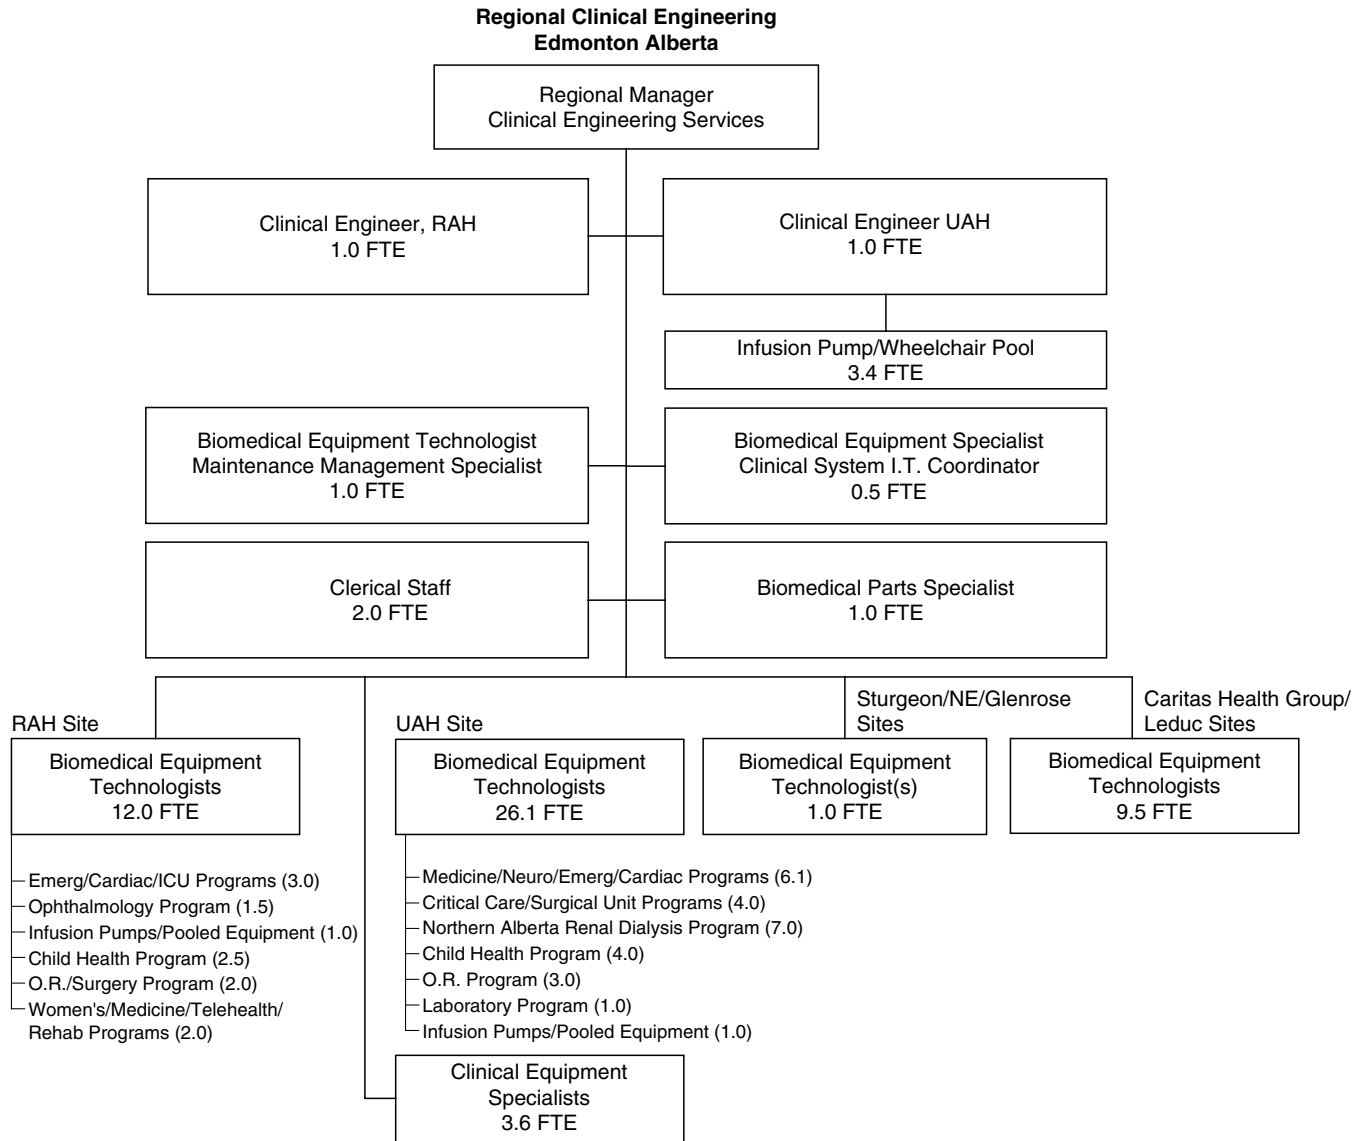

Figure 17-2 Regional clinical engineering: Edmonton, Alberta.

Accreditation and Peer Review

The Canadian Council on Health Services Accreditation (CCHSA) (HSA, 2001) is a non-profit, nongovernmental organization that is similar to the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) in the United States.

The CCHSA provides health services organizations with the opportunity for voluntary participation in an accreditation program based on national standards. In recent years, these standards have moved away from prescribing what a hospital should look like, to emphasizing patient outcomes. Sections that address equipment management have been weakened, and quality measurement and quality improvement have been given much greater emphasis.

This situation was the stimulus for the development of the Clinical Engineering Standard of Practice for Canada and an associated Peer Review Process, under the sponsorship of the CMBES ((Easty and Gentles, 2003)).

Communication in the Clinical Engineering Community

The members of clinical engineering profession in many of the larger provinces have organized local interest groups in order to facilitate communication. The primary mode of communication is e-mail, but most of these groups also hold regular meetings, either monthly or quarterly. Table 17-1 is a list of the associations and information on how to contact them:

In addition, the Canadian Medical & Biological Engineering Society (CMBES) sponsors a list-server, which can be joined by posting the message “Join CMBES” in the body of an e-mail sent to majordomo@messenger.sbgf.mb.ca. This list-serve is an active and informative communication medium for anyone practicing clinical engineering in Canada. The CMBES URL is www.cmbes.ca. The CMBES holds an annual conference in a different city each year. Information about upcoming conferences can be viewed on the society’s web site. Canadian clinical engineers also participate actively in international groups such as the Association for the Advancement of Medical Instrumentation (AAMI), the American College of Clinical Engineering (ACCE), and the International Federation of Medical and Biological Engineering (IFMBE).

Table 17-1 Canadian clinical engineering associations and contact information

Province	Group name	Contact information
British Columbia	Institute of Biomedical Engineering Technologists	www.astbc.org/fibet
British Columbia	Clinical Engineers Committee - B.C.	Jack.Hauzeneder@ex.thr.bc.ca
Alberta	Alberta Clinical Engineering Society	www.aces.ab.ca
Ontario	Clinical Engineering Society of Ontario	www.ceso.on.ca
Quebec	Association des physiciens et ingénieurs biomédicaux du Québec	www.apibq.org

Summary

The clinical engineering profession in Canada shares many similarities with the profession in other countries. The unique aspects have been determined by the geography, the politics, and the Canadian health care system. The future holds many challenges and much promise as the profession continues to evolve to meet the changing needs of the Canadian health care system.

18

The goal of this chapter is to demonstrate, using Estonia as an example, some general and country-specific aspects of a medical-technology management challenge, characteristic to a country that is transitioning from an Eastern European (Soviet Bloc) economy to Western technology and the free market. The paper is based on implemented and proposed activities to meet the challenge and provides conclusions and recommendations for transition. It expresses the results of medical equipment surveys and questionnaires in health care facilities of Estonia, practical work in the field, and available statistical data from Estonia and other sources.

Estonia and Its Health care System

Demographics

Geography: Area: 45,000 sq. km. (17,340 sq. miles). Population: Around 1.4 million.

Neighbours: South: Latvia; East: Russia; North: Finland (60 km across Bay of Finland); West: Sweden (120 km across the Baltic Sea).

Language: Estonian, which belongs to the same language family as Finnish and Hungarian.

History: Together with two other small Baltic states, Estonia has had a rich and turbulent history, mainly because of its location on one of the major contest lines between Western and Eastern Christianity and cultures.

Until the thirteenth century AD, the territory of Estonia was a weak, monolingual union of independent counties with traditional rules and religion based on nature. The country was conquered by northern Crusaders and converted to Catholic Christianity. It has been ruled by noblemen from the descendants of the Crusaders, with additions from other occupants throughout its history (i.e., Denmark, Germany, Sweden, Poland, and Russia). Estonia was under the occupation of the Czar's Russia from the early eighteenth century until 1918. The country gained its freedom during its War of Independence (1918-1920). Seized by the Soviet Union in 1940, occupied by Hitler's Germany during WW II, and reoccupied by the Soviet Union in 1944. It regained its independence in 1991 as a result of the *singing revolution*. Since independence, Estonia has established a Western constitutional democracy. It is a member of NATO and is in the process of becoming a member of the European Union (EU).
Prevailing religion: Lutheran.

Health Care System

Estonia's diverse health care system is rapidly changing because of major reforms. Quite recently, Estonia gained 60 hospitals with 10,000 acute care and long-term beds and a number of outpatient clinics. The goal of the ongoing health care Project 2015 is to convert these facilities to 13 acute-care hospitals with 3300 beds, and the other beds and hospitals are to be converted for nursing care. The goal will be achieved by closing some smaller hospitals and merging a number of hospitals into four to five chain-like facilities consisting of three to eight previously separate health care facilities.

Outpatient facilities (polyclinics) are converted mainly into group practices of family practitioners, with the addition of some specialized care. Private outpatient hospitals and specialist practices are emerging, especially in surgery (e.g., plastic surgery; orthopedic; urological; gynecology; ophthalmology; and ear, nose, and throat (ENT)).

Primary care is based on recently the established institution of family practitioners. There are 800 practices each with an average of 1700 patients. Practices are private by statute. Dental care facilities number 460 and consist mainly of private practices.

Health care is mainly financed by social tax (13% of salary), a state budget (e.g., ambulance service), and, increasingly, additional out-of-pocket payments by the general population. Total medical expenditure is estimated at 6 to 7% of the gross domestic product (GDP).

Total yearly medical device purchases by hospitals are estimated at \$30 million (including disposables and accessories). Out of this total, the serviceable equipment is valued at approximately \$10 million. To this sum, purchases by dental and family practices, emergency service, devices for handicapped persons, over the counter (OTC) directly to the population add approximately \$10 to 15 million, mainly for non-serviceable devices. The total installed base of serviceable equipment in all of Estonian hospitals is estimated at \$120 to 180 million (based on the purchase price). The annual outside-contract equipment service is estimated at \$1.5 million.

Challenges of Health Care Technology Management in Transition

Health care system reform, transition to Western technology, and conversion from Russian language-oriented and centralized Eastern European common market (EEM) to

English language-oriented, free and diverse Western market (WM) cause many challenges. Some of these are listed below:

The Need to Convert Technical and Language Skills of Technical and User Personnel

The EEM had an equipment base where the number of manufacturers was limited to two or three for each kind of device. Therefore, it was easy for a technician to become proficient in servicing this limited and homogeneous device population. The sophistication was modest and lagged behind mainstream WM equipment by 5 to 15 years on the average. Because of this lag, only relatively proven design and performance solutions were implemented and entered the market. User manuals, technical manuals, documentation, and related materials were predominantly in Russian. The training courses were also held in Russian, with the exception of general training, which was provided in national languages. The content of technical documentation was strictly standardized and well covered. Compared to WM devices, however, the documentation frequently was not user-friendly.

Conversion and Decentralization of Decision making

In EEM, devices were distributed, rather than sold, by governmental institutions to health care facilities. Because of strict standardization, the decision makers had no involvement with the devices. Therefore, they did not care about the content and performance characteristics of acquired devices and accompanying documentation. In the WM, the responsibility for specifying, vendor qualification, procurement, and maintenance rests with the individual health care facility within the legal and regulatory environment of the government.

Four- to Ten-Fold Increase in Device, Hand Tool, and Test-Equipment Prices

In EEM countries, the labor cost was, and still is, many times lower than in WM. In addition, standardization, limited product selection, dictated prices, and retarded technology further reduced the cost of EEM devices. The transition to Western technology and WM caused a four- to ten-fold increase of device prices for health care facilities in the transitioning countries. Hand tools and test devices purchased on the WM present a similar price challenge. Therefore, considering local purchasing power, the relative cost is four- to eight-fold as high as for a buyer in the West.

Steep Decrease in Availability of Specialized Training

Because of the limited size of the local language market, the training for technical staff is not economically feasible for the WM vendors. At the same time, the cost of one day of training abroad is comparable to a hospital technician's monthly salary. Both hospitals and private companies suffer from the lack of trained technical staff because of the high price of courses and training available in English.

The Need to Cope with Conversion from Fixed Prices of the EEM to Floating and/or Negotiated Prices of the WM

In the EEM, the prices were negotiated between the manufacturer and the centralized governmental institution. For WM purchases, all of the Soviet Union acted as a single, centralized group purchasing organization. The hospitals had to accept the result at a fixed price. As a result, hospitals had no experience at negotiating prices. Consequently, during the initial seven to ten years of the transition, facilities typically paid the full list price. Another related problem was the economic loss that stemmed from poorly drafted procurement specifications and the lack of internal standardization.

Diverse Installed Equipment Base

Currently, three subgroups of devices can be identified in Estonian hospitals:

1. Old (and outdated) EEM devices – degraded in technology and quality, but well supported with documentation and well known by technicians who were trained during the Soviet time
2. Equipment installed between 1990 and 1995 through intensive humanitarian aid – mostly used devices of newer technology and quality but poorly supported because of inadequate technical documentation
3. New WM devices purchased after 1995, which now carry most of the workload in hospitals – latest technology, improved quality, and well supported by private companies, poorly supported by in-house technicians who have limited access to technical documentation

Efficacy of Service Resources

The above-described diverse equipment base in the hospitals, combined with limited budgets and lack of trained staff, presents a significant maintenance challenge. There are two ways to reduce the device service costs: Increase the efficacy of service resources or reduce service of the device.

During the first phase of transition to the free market, the majority of hospitals lacked the technology management experience and tended to overutilize the second of these options. This resulted in rapid deterioration of quality and performance of both used and recently purchased equipment.

The Need to Convert the Legal Environment and Market Surveillance Systems Related to Medical Devices

In the European Union, of which Estonia stands as a candidate for membership, the safety-vigilance system relies mainly on customer activities and complaints. (See Chapter

125) It depends on re active, rather than proactive, market control. Expulsion of ineffective or useless devices from the market is expected to be performed mainly by market forces. In order to be effective and to avoid heavy losses of scarce health care resources, such a system calls for technologically competent hospital personnel as customers.

The Need to Have Reliable Device-Related Statistics to Support Legislative and Decision Making Processes

The EEM was a highly standardized and centralized health care system. The local health care facilities in Estonia had no involvement with the data collection or decision making of the central authorities. Equipment maintenance in hospitals was centrally controlled. Therefore, Estonia's independence brought with it a large collection of legislative, regulatory, and decision making challenges. Data collection, equipment databases, and statistics were necessary to support local hospital decision making, regulatory activities, and legislative action. A number of other, mainly temporary, problems resulting from the rapid transition process exist and need attention.

Conclusions and Recommendations

The majority of the above-described problems will be mitigated or solved, even though sometimes the process is agonizingly slow, particularly under the pressure of a diverse set of market forces. During transition, special attention must be given to the following five factors:

1. Policy, legislation and regulatory action

The interrelation of safety, performance, and availability of devices needs to be addressed during the development of legislative and regulatory systems. Policy and legislative work in Estonia is guided by the European Union requirements. A number of government laws and Social Ministry regulations have been issued. Estonia has made considerable progress during its first five-year Health care Master Plan (i.e., 1995 to 2000). The current health care reform activities are conducted within the framework of the Health care Project 2015.

2. Efficient management of resources

The transition from centralized to decentralized decision making at the country and health care facility levels represents a major cultural change in Estonia. The four- to ten-fold increase in relative cost of equipment from EEM to WM prices creates a major management and budgetary challenge. Management must provide considerable additional attention to technology management and acquisition practices. Budgetary and manpower planning is necessary to ensure that medical devices are adequately maintained and that they operate safely and effectively.

3. Equipment database and statistics

The transition from EEM to WM represents a revolutionary change in the way equipment is procured. Efficient and effective acquisition of equipment by hospitals requires access to actual (independent) price, safety, and performance information. (See Chapters 33 and 34.) This is especially critical for a small economic area with a unique language. Appropriate resource allocation to medical economics and improvement of data collection methods to guide the transition period are essential. However, some initial data collection will be needed before conclusions and projection of trends can be made.

4. Education and training

Specialized education, training, and retraining of the medical and technical staff in medical device technology management require concentrated efforts and resource allocation by health care, governmental, educational, and international organizations. Isolated private-sector vendors are not well-suited for such education and training. Because of the limited market size, education and training are of questionable profitability for the local provider. The importance of language and terminology issues are frequently underestimated, but they should not be. The Medical Technology Plan of Project 2015 estimates the country's medical physics (MP) and biomedical engineering (BME) staff requirements in the order of 150 to 200 specialists. The plan recommends a ratio of 1:4:10 among physicists, engineers, and technicians. During the Soviet period, there was no formalized education in the MP and BME fields. To address the educational, training, and retraining needs, the Tartu University established in 1996 the Training Center of MP and BME, offering degrees at the master's level. It provides quality control and support to hospitals across the country. The Tallinn Technical University established the Biomedical Engineering Center in 1994, offering degrees at the masters and doctoral levels. High-school education in these fields is in the planning phase.

5. Coordinated and integrated action.

Development of the legislative system, medical devices industry, medical gement in hospitals, and research and development work in medical technology as separate systems is not effective, especially in a small economic area with a unique language. These should develop together and should be kept in mind constantly and equally, to ensure effective allocation of limited financial and human resources.

Summary

Reforms in the health care system of a transitioning country can be successful only as long as it is realized that the reforms, by their very nature, are technology-driven. Health care technology and its associated cost in all countries advances faster than their GDP. To meet their population's increasing expectations, the transitioning countries must conduct major reforms with highly limited resources. Therefore, effective technology management is particularly critical for these countries.

19

Clinical Engineering in Germany

Vera Dammann

Department of Hospital and Medical Engineering,
Environmental, and BioTechnology
University of Applied Sciences Giessen-Friedberg
Giessen, Germany

More than 6000 clinical engineers are working in industry, hospitals, and service companies in Germany today. The legal framework for clinical engineering work in the hospital is the Medical Devices Law of 1994, which is based on the European Medical Devices Directives (MDD, 1993; see also Chapter 125) and accompanying directives and regulations concerning ownership, operation, maintenance, and calibration of medical devices. Clinical engineering services in German hospitals are usually carried out by clinical engineers and medical technicians, integrating external services of the manufacturers and service companies. German clinical engineers and biomedical engineering technicians are affiliated in the Fachverband Biomedizinische Technik e.V., fbmt.

Professional Field of Clinical Engineers in Germany

Education of clinical and biomedical engineers started in East Germany in 1953, in West Germany in 1970. Thus, today it is estimated that more than 6000 specialized professionals are working in the field of clinical engineering (Dammann, 1994; Dammann, 2000). The majority found jobs in the medical device industry; and just a minority is working in hospitals. Clinical engineers are supported by skilled craftsmen and biomedical engineering technicians (in Germany, these are simply called “medical technicians”), who attended a special two-year technician college after completion of a three-year apprenticeship in electrical or mechanical technology.

Employers and Jobs of Clinical Engineers

Owing to their interdisciplinary education, clinical engineers are very flexible and thus are able to find adequate jobs. Table 19-1 lists, in descending order of size, the number of CE jobs available.

Survey of Hospitals

Provoked by acute financial problems in the German health insurance system, several laws and directives were revised. The consequences for hospitals are enormous, as the following list shows:

- Budgeting instead of full refinancing of expenses
- Proof of all costs related to special patient treatment procedures and to single departments
- Quality assurance in diagnostics, therapy, and nursing
- strengthening of ambulatory care and reduction of nursing days
- Introduction of a diagnostic-related group (DRG) system and the concept of evidence-based medicine

Many hospitals have closed or reduced their number of beds as a consequence of financial pressures. Today (BFG, 2000), the situation is as follows:

- There are 2200 hospitals, about 10 % of which have more than 500 beds, and among these are 35 university hospitals with up to 2500 beds (e.g., “Charité” in Berlin)
- The average number of beds per hospital is 250
- There are 1400 diagnostic and/or rehabilitation clinics with an average of 135 beds per clinic.

Increasingly more hospitals, including university hospitals, have been converted from public institutions to foundations or private enterprises, with the advantages of better management possibilities, better payment of staff, and, especially, improvement in financing and budgeting. Many hospitals have given up in-house service departments such as catering, laundry, maintenance, clinical chemistry laboratory services, and even clinical engineering services. Instead, they use external service providers.

Legal Requirements in Clinical Engineering

The Law

In the course of harmonization with the EEC Directive on Medical Devices (MDD, 93/42 EEC [MDD, 1993]), the German government signed the German Law on Medical Devices (Medizinproduktegesetz, MPG [MPG, 1994] on August 2, 1994. Like the EEC directive, it is not directed primarily to the owner and operator of a medical device, but to the manufacturer and vendor. It especially defines the prerequisites and procedures for the CE-mark and for a national vigilance system (Pallakarakis, 2003). In addition to the MDD, however, it requires the following at the levels of the manufacturer, importer, and vendor:

- A special person who is responsible for the handling of safety information on medical devices; and
- Special knowledge of the salespersons, advisers, and instructors, who are now called “medical device consultants” (*Medizinprodukteberater*).

The law also authorized the Ministry of Health to publish and enforce special ordinances concerning the following:

- Clinical evaluation of medical devices
- Storage, purchase, sale, information, consulting, and instruction on use and operation, including
 - documentation
 - personal requirements
 - premises
 - hygienics
 - labeling of containers for medical products
 - securing supply
 - handling of medical products that are unsuitable for sale and use
 - regular checks of medical products and documentation of these checks (in the sense of storage checks)
- Education and qualification of medical device consultants
- Instruction of the owner and user of medical devices
- Technical safety checks
- Calibration of measuring devices
- Function checks
- Inventory
- Recordkeeping for dedicated medical devices

All owner-related duties (Böckmann, 1994; BGBl, 1998) are typically the responsibility of the in-house clinical engineer.

System of Governmental Authorities

As Germany is a federal republic, the states (*Länder*) are responsible for supervision of safety in health care. The federal Ministry of Health (<http://www.bmgesundheit.de>) enacts the law and the regulations. Together with the relevant department of the federal Ministry of Health, the state Ministries for Occupation and Social Affairs formed a medical device committee in order to harmonize all procedures. In a particular state, the local trade-supervisory boards (*Amt für Arbeitsschutz und Sicherheitstechnik*), which are the next governmental level below the Ministry of Occupation and Social Affairs, are responsible for the supervision of hospitals and medical device manufacturers and traders. They carry out inspections of documentation and procedures and investigate accidents and incidents. Because maintenance and, especially, safety checks

Table 19-1 Jobs available to clinical engineers by employer and field of specialization

Employer	Field
manufacturer of medical devices	marketing and sales support, technical service application, training product management project management regulatory affairs quality management software development hardware development
hospital	central clinical engineering radiation therapy (as medical physicist) hospital engineering (technical director) technical support in other clinical department
service company* engineering office*	maintenance, especially safety checks, repairs, and calibration hospital and hospital equipment planning software development assessment of devices (for certification or in case of accident) certification ("notified body") advisory service (especially quality assurance and regulatory affairs) authoring of manuals and tutorials training
public administration, ministry	supervision regional planning

*Including self-employed in own enterprise.

and calibration of medical devices need adequate knowledge, experience, and equipment, the boards also may check workshop equipment and the qualifications of staff.

The German federal Office of Drugs and Medical Devices (*Bundesinstitut für Arzneimittel und Medizinprodukte* (BfArM) (<http://www.bfarm.de>) was assigned to medical device matters such as central recording and assessment of observed and reported risks associated with medical devices as well as coordination of measures where necessary. The databases of the governmental vigilance system are maintained at the German Institute for Medical Documentation and Information (DIMDI) (<http://www.dimdi.de>).

Clinical Engineering Services—Tasks and Structures

Because of legal demands, nearly every hospital employs at least one medical technician. The minimum list of duties includes maintaining the inventory, device records, and schedule of safety checks and calibrations. At the next level, the medical technician or clinical engineer carries out first-line service, manages external orders, controls service contracts, and checks the bills.

A full clinical engineering service covers the entire life cycle of a medical device within a quality assurance system (Böckmann and Frankenberger, 1994; Nippa and Fritz, 1995, 1998, 1999). This entails the following:

- Equipment and investment planning
- Technology assessment and specifications development
- Safety of combination of devices and networks
- Call for tenders
- Ordering
- Contracting with external services
- Installation preparation, including cooperation with architects and hospital engineers
- Acceptance tests
- Installation
- Final check and placing in operation
- Consulting and training of users
- Functional and safety checks
- Calibration
- Preventive maintenance
- Repairs
- Cooperation with purchasing officer for the purchase of consumables
- Logistics and environmental protection concerning the supply, operation, and recycling or disposal of consumables
- Documentation (e.g., inventory and device history) [VDI 2426]
- Analysis of incidents and accidents
- Contact with supervising authorities
- Budgeting
- Quality assurance
- Reselling, disassembly, or disposal of device

The clinical engineer may be involved in clinical trials with new devices, either as the person responsible for technical service or at the application level.

As Germany is a country of rather short distances, external services compete strongly with in-house clinical engineering groups.

In-house Structures

On average, in-house clinical engineering structures have the following:

- Clinical engineer (with a university degree) per 500 beds
- Medical technician or further-qualified craftsman per 100 beds
- Clerk per 1000 beds

Various models exist for integrating the clinical engineering service into a hospital's organizational structure.

Large and Medium-Sized Hospitals

The clinical engineering service may be central or decentralized, with technicians in small, individual workshops in the medical departments; e.g., anesthesia and intensive care unit (ICU). The head of clinical engineering is usually an experienced clinical engineer or physicist. Increasingly more clinical engineering (CE) groups have their own budget, develop a business plan, and make decisions on outsourcing tasks; e.g., regular electrical safety checks, full-service MRI contracts, or single repair orders.

The CE group may be an independent department, with its head reporting directly to the hospital director. If the hospital has a directorium, the head of CE may even be member of the directorium. In other cases the CE group is just a sub-department of the technical services, reporting to the technical director of the hospital.

Along with CE groups with hospital-wide responsibilities, some medical departments employ one or more clinical engineers or medical technicians. For example, many clinical engineers work in radiotherapy departments as experts in medical physics and are responsible for dosimetry, therapy planning, and radiation protection.

Small Hospitals

General hospitals with fewer than 200 beds employ one or two medical technicians. They are responsible especially for documentation according to legal requirements, carrying out regular functional and safety tests, some first-line service, and hiring external services for more complex or extensive work.

Highly specialized hospitals such as cardiac surgery or oncology hospitals with just one medical department usually have a clinical engineering group, offering full CE service, including, in some cases, the operation of complex medical devices.

External and Mixed Services

Clinical engineering services are offered externally by the following models:

- Manufacturers traditionally, offering such services as
 - single-maintenance action
 - part or full maintenance
 - cooperative service with in-house staff
 - consulting and/or full clinical engineering service by a dedicated subcompany
- Small, locally operating service companies that
 - specialize in single tasks such as safety tests or calibration according to medical device regulations
 - act as privatized service centers that are responsible for one large hospital, which may be a shareholder of the service company, or for several hospitals in the region, in some cases selling medical devices and/or consumables
- Small, supra-regionally operating service companies, that could include
 - distributors who import, sell, and service medical devices
 - consultants in hospital equipment planning, IT technologies, quality assurance, organization engineering, and surveying or certified experts
- Large, nationally or internationally operating service companies that offer
 - consulting services
 - partial or complete clinical engineering service with or without engineers or technicians, permanently delegated to a single hospital (so-called external in-house service).

In contrast to the outsourcing actions of the early 1990s, hospitals now tend toward mixed services, with at least one clinical engineer or technician who keeps the records and has the knowledge of the hospital.

Affiliation of Clinical Engineers and Biomedical Engineering Technicians

In 1984, the *Fachverband Biomedizinische Technik e.V.*, (FBMT) (<http://www.fbmt.de>) was founded by 40 clinical engineers. Today, the FBMT has more than 500 members who cooperate in regional and working groups. The association offers continuous education in seminars and workshops and holds a large congress in Würzburg every year. (Proceedings are available in print and on CD-ROM.) The scientific journal *Medizintechnik, mt*, is their forum and is distributed to all members. New initiatives include a European Alliance of Clinical Engineering, together with the national CE associations of the neighbor countries and a certification board for medical technicians.

Clinical Engineering in Brazil

Lúcio Flávio de Magalhães Brito

Certified Clinical Engineer
Engenharia Clínica Limitada
São Paulo, Brazil

Brazil: The Country

In describing the current practice of clinical engineering in Brazil, it is helpful to have some background information about the country.

Demographics

Brazil is a country with a population of over 169 million inhabitants distributed over an area of over 8.5 million square kilometers. That results in a population density of 19.9 inhabitants/sq. km. In 1980, the infant-mortality rate was 68 per 1000 births. In 1999, this index fell to 34. Adults are living longer. The life expectancy of those born today in Brazil is 68 years. The data of the Brazilian Institute of Geography and Statistics (IBGE) reveals that the population growth is decreasing and that the migration toward the cities is increasing (IBGE, 2001). New economic opportunities are appearing throughout the country, but social inequality continues.

Geography

Brazil has 26 states and one federal district where Brasília, the capital, is located. The map of the country is shown in Figure 20-1.

Hospitals

The number of hospitals in Brazil and its distribution in federate units (FU) is presented in Table 20-1.

Medical Device Market

In December of 1998, the market for medical devices was \$13 billion. Of this, \$500 million (38.46%) corresponds to diagnostic imaging equipment. The ultrasound market, for instance, began to grow in 1994 and in 1998 the annual market was about \$80 to \$104

million. The annual growth rate was around 20% and represented 50% of the volume of the medical device market in Latin America.

Medical Device Industry

The Brazilian national industry of medical devices is represented by the Brazilian Association of Industry of Medical Devices and Equipment (ABIMO). ABIMO was created in 1962 by 25 companies out of a total of 40. ABIMO is divided into five groups: Medical hospital equipment; radiology and medical imaging; dentistry; laboratory; and implant and supplies.

In 1996, ABIMO member companies had the following profile:

- 80.6% of the companies were of domestic capital, and 19.4% foreign capital
- 39.7% were small in size, 45.5% were medium, and 14.8% were large

Between 1991 and 1996, participation in ABIMO of small companies decreased from 47.1% to 39.7%, while the participation of large companies increased from 4.4% to 14.8%.

The revenue of the market was the following:

- 1994: \$1.31 billion
- 1995: \$1.44 billion
- 1996: \$1.96 billion
- 1997: \$2.30 billion

In 1997, 93.9% of sales were domestic, and the rest were exports. In 1998, ABIMO had 230 members.

ABIMO currently has 243 members. They comprise 80% of the national market. Altogether, they manufacture the products to equip about 80% to 85% of a general hospital. Many of the ABIMO members have been in existence for over 100 years.

In the year 2000, the ABIMO stood as follows (Rodrigues, 2001):

- The section billed R\$ 3,450,000,000 and it exported FOB \$149,901,439.
- Composition of the capital of the companies of ABIMO was of 80% national and 20% foreign and mixed.
- 28% of the companies were small; 68.7% were medium; and 3.3% were large.

(9) index of potential market

- The customer base was 48% private sector; 44.3% government; and 7.7% Unified System of Health (SUS).
- 46 (22.5%) of the companies made products certified by the NBR-IEC standards; 40 (19.6%) CE/UC; 33 (16.2%) FDA; 8 (3.0%) UL; 83 (40.7) GMP, and 23 (11.3%) other standards.
- 125 companies had no ISO certification; 71 (34.80%) had ISO 9000 certification; and 8 (3.93%) had ISO 14000 certification.
- ABIMO generated 37,679 direct jobs, of which 21.4% were for professionals with college degrees; 48.2% were for those with high-school degrees; and 30.3% were for those with other qualifications.

Problems

One of the fundamental problems found during the 1980s was the lack of clear policies for planning and administration of medical equipment, especially for the more innovative technologies. Some of the problems that were most difficult to solve concerned the following:

- Ways to manage medical equipment and devices, ranging from simple ones, such as thermometers, to CT scanners
- Ways to present data on safety and efficacy on each new technology
- Ways to obtain premarket evaluation of some technology
- Ways to obtain data on life expectancy of equipment
- The amount of money that a country should invest in health care technology
- The kind of technology (e.g., drugs, procedures, equipment, and administrative technology) and information that a country should invest in
- The costs to operate medical equipment within an entire country
- Replacement costs of each technology

Between 1980 and 1990, Brazilian authorities began to study and to understand this problem of planning and administration of medical equipment. The strong participation in international meetings that considered this theme in a global way was helpful (WHO/PAHO/FDA, 1986). Brazil started to promote the exchange of information, closer communication, and cooperation with other countries (USDC, 1990). Brazilian authorities understood that the lack of specialized manpower was a serious problem and that a corrective action should be taken (Wang and Calil, 1991; MoH, 1992; WHO, 1989). The following recommendations emerged:

- Training, alone, cannot solve the problems related to health care equipment management.
- Clinical engineering manpower development should be a national priority.
- Particular attention should be paid to policy formulation, manpower development physical-infrastructure strengthening, and information support.
- Highly specialized training should be conducted at the global level.
- Training always should be linked to a service workshop in a nearby hospital in order to give trainees practical exposure.
- A wide and serious gap in availability of training materials existed.
- In Brazil, positive conditions exist for developing a program to minimize and to start to control these problems.

From 1991 to 2000, the results of the efforts of the previous decade began to appear. In 1991, six Brazilian engineers were trained at the First Advanced Clinical Engineering Workshop in Washington, D.C. (See Chapter 70.) In the same year, a Health Care Technology College opened in Brazil. It has a 3-year program that trains professionals called “health care technologists,” who are able to operate and maintain medical equipment. Since 1994, this college has trained approximately 28 new health care technologists each semester.

In 1992, the Brazilian Health Ministry published a Term of Reference for technicians training in maintenance of medical devices. That document described the fundamental importance of the biomedical equipment technician to the proper maintenance of equipment and proposed a strategy to qualify professionals in the Brazilian health care field. It presented the following scenario:

“The world market for medical equipment was, in 1998, \$36.1 billion. Assuming that around 5% to 10% of the value of the equipment needs to be spent on maintenance, one arrives at an amount of approximately \$2.7 billion in annual expenditures. As a consequence of the growth of the installed base and the increase of the technological complexity of the equipment, the expenses in maintenance in these countries grew by 50% in the last five years (1988-1992). In Brazil, the installed base of equipment operating in the public health institutions is nearly \$6 billion, representing annual expenditure for maintenance on the order of \$450 million, in other words, 3.5% of the Budget of the Union for Health in 1991.” (DOU, 1991)

In 1993 and 1994, four federal and state universities began a program to train clinical engineers to practice in Brazil. These courses are full-time programs that lasted 12 months. Approximately 160 clinical engineers graduated in two years. During the 1990s, many other initiatives were undertaken, including the following:

- Master’s and doctoral programs in biomedical engineering were strengthened and consolidated.
- Some new technical schools started while others consolidated.
- The International Certification Commission certified nine Brazilian clinical engineers, and a Brazilian Board of Examiners for Clinical Engineering Certification was created.
- Many meetings relating to clinical engineering were organized.
- At least four books relating to clinical engineering were published.

Reinforce to the Reorganization of the Unified System of Health (REFORSUS), created at the end of 1996 through a \$650 million loan agreement with the Brazilian government,

the InterAmerican Bank Development (BID), and the World Bank (BIRD), has been investing in the recovery of Brazil’s health care physical infrastructure. REFORSUS invested in the purchase of medical equipment, hospital installations, and movable units; the execution of reform works; the enlargement and conclusion of establishments of health; and in projects for the improvement of the administration of the national health system. In order to operate properly, REFORSUS organized a team of health professionals, including clinical engineers, to evaluate needs and to specify and select medical equipment and hospital facilities in the institutions selected for this project.

The National Agency of Sanitary Surveillance (ANVISA) was created by Law No. 9782 on January 26, 1999. It is a regulatory agency characterized by administrative independence, job stability for its managers, and financial autonomy. In the structure of the Federal Administration, it is linked to Ministry of Health. ANVISA began an intensive program to develop agents specializing in sanitary surveillance to work in the medical device and equipment area. Many of these agents were engineers. Clinical engineers participated as teachers in these programs.

Employment

Brazil has been doing its homework. Consequently, it is better prepared than it was 20 years ago. Today, the job market for Brazilian clinical engineers is broad and diverse.

Hospitals

Clinical engineers who work in hospitals are engineers or health care technologists that have taken specialized courses in clinical engineering. Their duties vary according to the institutions where they work but, in general, include those defined by American College of Clinical Engineering. (See Chapter 130.) They usually report directly to the administration of the hospital, where their responsibility is to provide support decisions that involve medical equipment or hospital facilities. Few clinical engineers have the opportunity to act exclusively with medical equipment.

Industry

Usually, industry offers clinical engineers opportunities to serve in the maintenance area. Some engineers who have managerial abilities also act in administrative areas of these organizations. The development of new equipment sometimes is done by clinical engineers, although it is more common to have this activity performed by biomedical engineers. Besides maintenance, the area of sales is also available for clinical engineers and for health care technologists.

Academia

Another option for clinical engineers, biomedical engineers, and health care technologists is to work in academia. There, among other functions, they support and conduct research leading to new procedures. It is a highly sought-after atmosphere among health care technologists. About 35% of recent graduates, along with 30% of those who already have graduated and are active in the job market, seek postgraduate degrees in biomedical engineering and specialization in clinical engineering.

Consulting

Consulting activities in clinical engineering experienced a considerable increase over the last five years. This fact demonstrates that hospitals, health care industries, teaching institutions, health care companies, and the professionals involved in administration are much more conscious of the inconveniences and waste of resources that will ensue if they make the wrong decisions. Clinical engineers, in this market segment, act as mediators in the decision processes. They serve as objective interfaces, translating the needs of the suppliers for the consumers of these technologies. In short, the clinical engineer offers support for the right decisions and investment of resources.

Companies

Many clinical engineers, observing the need of hospitals, meet those needs (Blumberg, 1987). Some have worked independently as consultants. Others have formed companies. These clinical engineers are currently engaged in consulting, maintenance of biomedical equipment, validation of processes and equipment, and sales. Today, Brazil has only a few professionals in clinical engineering companies. However, because of the specialization and the emergence of this new profession, a number of companies have been established in several Brazilian states. With the increase in competition, the search for excellence and quality will result in patients receiving a higher quality of care.

Sales

Selling medical equipment has become highly specialized, to the point where industries are incorporating many clinical engineers to perform this function. The clinical engineer in sales should understand the technical aspects of the product, equipment operation, physiologic interactions, cost analysis (e.g., depreciation, amortization, and leasing), and clinical applications. Many specialists in clinical engineering are practicing in this area.

Conclusion

The role of clinical engineers in the Brazilian health care community has changed considerably over the last two decades. This profession, which not long ago was unrecog-

nized, is becoming more highly respected and appreciated. Clinical engineers are now in demand. Many hospitals and manufactures have a clinical engineering team that is composed of more than a clinical engineer. The team acts to minimize losses of resources in health care technology management. In this context, clinical engineers play a fundamental part in the team as it decides and recommends particular technology to buy. Today, clinical engineers are working with doctors, nurses, and administrators.

Brazil is changing, and clinical engineers in the country are changing with it. These changes are accelerated by the increased interaction with the world at large. In Brazil, clinical engineers have much work to do.

Clinical Engineering in Colombia

Jorge Enrique Villamil Gutiérrez

Independent Technology Consultant for Health Projects
Bogota, Colombia

Colombia's law 100/1993 defines all matters related to the Social Security System in Colombia. This law resulted from modifications in existing health services regulations. The National Social Security System was designed to guarantee every citizen's access to the health system. The guiding principles (CoC, 1993) of the system are as follows:

- **Efficiency:** The best social and economic utilization, in an adequate, timely, and competent way, of administrative, technical, and economic resources for the security of the society.
- **Universality:** Guaranteed protection for all people without discrimination.
- **Solidarity:** Mutual help from the strongest to the weakest among people of all ages, economic groups, regions, and communities.
- **Integrity:** Coverage of all contingencies affecting health, economic situations, and life conditions.
- **Unity:** Politics, institutions, regimes, and procedures working together.
- **Participation:** Active participation of the community, which benefits from the system, in organization, control, supervision, and audit of the system.

The system has two major components known as the "contributive regime" and the "subsidiary regime." In the contributive regime, workers with higher incomes are affiliated with an administrative and financial company known as EPS. EPS controls the contributions of workers and has contracts with several IPS centers (institutions that deliver health services, such as hospitals, health centers, and diagnostic centers). These institutions can be either public or private. EPS makes contracts with several IPS centers to guarantee that all affiliated workers and their families will have access to health services. For their contributions, workers and their families receive a basic package known as POS [Mandatory Health Services Plan (Contributive Regime)]. For additional services, the worker must pay an additional fee. A percentage of the contributions of these workers goes to a National Fund known as FOSYGA, the solidarity and guarantee fund. Its resources are used to help to pay for health services for low income workers.

Low income workers belong to the subsidiary regime. Municipalities pay for the affiliation of these workers. Every person is affiliated with an administrative and financial company known as ARS [Administrative Enterprise (Subsidiary Regime)] and is classified in a social and economic table of reference. The citizen receives a card containing personal data and showing the classification. With that classification, they have the right to receive basic health services known as POSS (Mandatory Health Services Plan Subsidiary Regime). The subsidiary regime pays the IPS centers for services provided to these people according to the POSS rate schedule. The citizen pays a percentage of the cost according to his or her classification. The subsidiary regime covers all the costs of the poorest workers.

The National Social Security System provides participants with certain rights, as follows: The right to select the EPS and the IPS centers; the right to receive the health serv-

ices included in the POS; the right to include the family as beneficiaries of the health services; and the right to select the physician or specialist. Table 21-1 and Figure 21-2 show how many people have Social Security and how the system works (Correa, 2001).

In 1991, Colombia adopted a decentralized government system that gives autonomy to the regions of the country. For every aspect of public administration, the central government gives the political orientation that is mandatory for governors, mayors, and directors of public institutions. But the priorities are set, and the decisions made, by the departmental authorities or the mayors of cities. For example, health and education social services are the responsibility of the mayors. Mayors are the heads of the local health organizations and define, with the councils, the development plan priorities. The mayor selects the managers of the hospitals from a group of three candidates selected by the community, health authorities, and local authorities. The managers serve for at least three years.

To develop and deliver health services efficiently, cost-effectively, and with opportunity, the IPS centers (hospitals) are considered to be companies with autonomy to manage their resources and must compete with other health companies (other hospitals) in their area of influence. To sell their services through contracts with the EPS, the hospitals must fulfill mandatory requirements relating to physical infrastructure, equipment, human resources, administrative organization, controls, audit, and maintenance. These conditions, known as "Essential Requirements," are defined for each health service that the hospital offers. The hospital's manager certifies to the local or regional health authority by means of an official declaration that the services offered comply with the essential requirements and that the hospital is able to operate and provide those services. The National Superintendent of Health and regional and local health authorities assure that the hospital does, in fact, comply with the essential requirements. The mission of the Superintendent and the authorities is to guarantee that the health services provided to their citizens are of excellent quality and are cost-effective and adequate.

Hospitals and Health Centers

Public Sector

In Colombia, health services are provided at three levels: Primary, secondary, and tertiary. The primary level comprises health posts, the health centers (with or without beds), and the local hospitals. Health posts are located in the counties; the health centers could be located in counties, small towns or big cities; and local hospitals are normally located in small towns or, if of a high level, in big cities. Local hospitals normally offer outpatient medical and dental consultation, normal obstetric care, basic surgical procedures, and basic clinical laboratory and X-ray services. Some of them offer basic emergency care. The number of beds varies but average between 10 and 25 per hospital. Health services

Table 21-1 Population with Social Security (Thousand)

Concept	1995	1997	1999	2000
Population Insured	36,558	40,018	41,439	42,299
Contributive Regime	6,708	13,065	13,652	13,454
Subsidiary Regime	4,800	7,026	9,325	9,365
Speical Regime	1,000	1,150	1,250	1,250
Total Insured	12,509	21,242	24,228	24,070
Converted (%)	32.44%	53.38%	58.33%	56.90%

in these establishments are provided by general professionals in medicine, dentistry, infectious diseases, and nursing. At the primary care level, there are 560 local hospitals, 2000 health centers, and 2705 health posts.

Secondary health services are provided by specialists with access to better infrastructure and equipment for diagnoses and treatments. There are 134 regional hospitals located in towns that have more than 15,000 inhabitants, and the number of beds available varies between 30 and 160, depending on the locations and services provided. Some hospitals offer specialized services like intensive care units. Some secondary level hospitals are located in big cities.

Tertiary care is provided in approximately 36 specialized public hospitals located in the main cities of Bogotá, Medellín, Barranquilla, Cali, Bucaramanga, Ibagué, Pereira, and Armenia. These hospitals have the most modern infrastructure and equipment needed for treatment and diagnosis, e.g., computerized axial tomography, automated clinical laboratories, nuclear medicine units, intensive care units, cancer treatment units, linear accelerators, and neonatal units. These hospitals have between 250 and 800 beds and have training programs for health sciences professionals.

Social Security Institute

The Social Security Institute (ISS) is a national institution, classified as an “Industrial and Marketing State Company” within the Labor Ministry. Its mission is to provide health, pension, and insurance services to workers. In the health sector, ISS has its own EPS and a network of IPS centers located in several cities. ISS has approximately 40 hospitals and a network of hundreds of small health facilities where affiliated workers and their families receive health services. For many years, ISS was the main social security provider in the country, but recently it has met with strong competition from private EPS and, as a consequence, has lost a significant percentage of higher income workers to EPS. Today, ISS has major problems that can be solved only by the strong intervention of the central government, which must make radical political and administrative decisions. ISS provides health services to a population estimated at between five and six million people and continues to be Colombia’s largest health services provider.

Private sector

Law 100/93 brought significant change in the private health sector. Many health enterprises were established and compete with public hospitals to sell services to the different EPS. Table 21-2 shows Colombia’s health organization.

Clinical Engineering Facts

The clinical engineer’s roles and responsibilities have changed dramatically over the past several decades. In the 1940s and 1950s, hospitals were so elemental that engineers were unnecessary. Problems could be solved by people who had elemental knowledge of electromechanics. Equipment was so simple and of such excellent quality that it could be kept operational for years with only basic maintenance. In the 1960s, electronics arrived, and a fast evolution began. The universities in Colombia had only classical engineering programs such as civil, mechanical, industrial, and electrical. No one studied any subject relating to modern clinical engineering. Health institutions were developed with financing from central government, religious communities, local communities, and philanthropists.

In 1968, under the administration of President Carlos Lleras Restrepo, a national institution was established, called Fondo Nacional Hospitalario (FNH) (FNH, 1991). FNH was

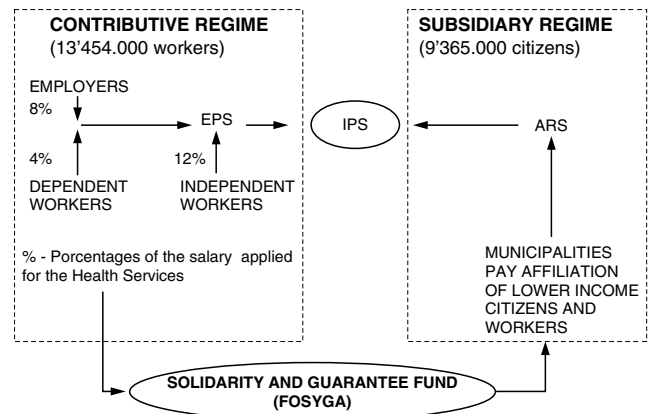

Figure 21-1 Colombian social security system.

charged with the responsibility of improving public hospitals, which were obsolete, inadequately equipped, and generally dysfunctional. This sad state was blamed on unwise investments and lack of proper planning. The contract made between the Health Ministry and the Social Security Colombian Institute (ICSS) establishing FNH defined the mission of managing the investments that were necessary to develop the public hospital network using economic resources from the central government and the ICSS. From 1970 to 1972, FNH began designing a national program targeted at 54 priority hospitals involving every aspect of planning, design, construction, equipment acquisition, and training programs for health professionals, technicians, and engineers. These hospitals, developed with modern ideas of infrastructure development, resulted in better health services for every citizen. To finance the program and to complete the construction and acquisition of equipment, the government increased taxes on beer sales by 8% and authorized international loans with banks and governments. The government also developed a methodology to define investment priorities.

From 1973 to 1992, FNH took out several international loans for new infrastructure development and new equipment acquisition in public and some private hospitals. The Engineering and Maintenance Division of the FNH developed training programs for the hospitals’ technicians and engineers. Technicians and engineers from Colombia and throughout Latin America benefited from these programs. In the 1970s and the first half of the 1980s, training programs addressed only traditional engineering, none involving medical equipment. Not until the second half of the 1980s did a few universities and technical institutes begin training programs in electromedicine and bioengineering. During the years of FNH’s existence more than 1500 technicians and 200 engineers received technical and administrative training. This training improved their skills and technical knowledge in hospital maintenance. FNH was closed in December 1993, as a consequence of the decentralization process that transferred the activities of the FNH to regional and local authorities. Since January of 1994, all processes relating to construction of new hospitals, equipment acquisition, and maintenance of the infrastructure and equipment have been decentralized and now are the responsibility of regional and local health authorities. In accordance with the priorities that the authorities define, hospital managers must plan, obtain, and expend resources on maintenance, acquisition of equipment, and human resources.

Maintenance Legislation

Law 100/93, which has resulted in better maintenance services in public and private hospitals, states in Article No. 189 the following:

Public and private hospitals, in which the value of contracts with National or Territorial Entities is more than 30% of their total income, must assign at least 5% of their total annual budget to maintenance of the physical infrastructure and hospital equipment.”

As a direct result of this article, every hospital must invest in maintenance every year to protect the physical infrastructure and equipment. Before 1993, investments depended only on the common sense of directors. Now, maintenance is an obligatory activity and is implemented based on strategies chosen by hospital administration.

In 1997, in accordance with Law 100/93, the National Superintendent of Health, as the governing authority of the General Social Security Systems, issued Internal Circular No. 29, which defined the need to develop in every hospital an annual maintenance plan, for which the authorities of each hospital (i.e., manager, chief of maintenance, and fiscal auditor) are responsible (NSH, 1997). The circular states, in part:

Hospital maintenance is understood to be the technical and administrative activities required to prevent accidents and to repair and maintain the infrastructure and equipment and activities that improve the functionality of equipment (Article 70, Decree 1769 of 1994).

The circular defines the maintenance objectives as follows:

- To guarantee the security of patients and the personnel who administer and use the physical resources of the hospital
- To support the health service in meeting the quality objectives ordered by law
- To ensure availability and efficient functioning of physical resources required to deliver health services and to help reduce the institution’s cost of operations

The annual maintenance plan is seen as the management tool that provides guidelines to the maintenance departments in every hospital. The plan must include the objectives; programming activities; and physical, human, technical, and economic resources to meet every hospital's objectives. It must include at least two chapters—one on physical infrastructure and the other on hospital equipment.

Physical Infrastructure

“Physical infrastructure” refers to the buildings; water supply and distribution systems; electrical distribution systems; communications; medical gases; and areas adjacent to the buildings, such as parking lots and grounds.

Hospital Equipment

Hospital equipment includes the following:

- Industrial equipment (e.g., electrical generators; boilers; water pumps; refrigeration and air conditioning systems; elevators; laundry; and kitchen and other similar equipment)
- Biomedical equipment
- Furniture
- Communication and information systems
- Equipment used for processing and duplicating information

“Biomedical equipment” is understood to be every machine or apparatus that uses one or a combination of electrical, electronic, or mechanical means for prevention, diagnosis, treatment, and rehabilitation in health services.

Every year before January 30, hospital managers and maintenance chiefs should send to the regional authorities their annual plan of maintenance, which should specify the priorities of the year, including their costs and action plan. The annual plan is an official document that must be signed by the manager, the maintenance chief, and the fiscal auditor. The authorities responsible for supervision will audit the plan to ensure adequate investment of resources. However, this process requires more control. Some hospitals do not obey the law because they either do not have an annual maintenance plan, do not make the investments detailed in the plan, or do not have adequate technical staff to manage the medical equipment technology in the hospital. The Health Ministry and the National Superintendent of Health must urgently attend to these lapses because the “Essential Requirements” refer directly to maintenance services and define actions that must be taken and information that must be available at any time. According to the essential requirements, every maintenance unit must do the following to comply:

- Have clear rules about the functioning of the service
- Plan the needs of spare parts and consumables
- Have the internal administrative forms to control the maintenance activities
- Plan and develop the annual plan of maintenance
- Have an inventory of spare parts and materials for urgent maintenance
- Plan the daily activities
- Supervise and explain the infection control policies of the institution
- Maintain an updated inventory of spare parts and tools required for service work
- Have a daily control of services performed
- Have maintenance records for each device in the hospital
- Have up-to-date blueprints of every network installed in the hospital
- Keep records of the down time of the equipment
- Make monthly evaluations of the preventive and corrective maintenance done
- Keep records of the response time to requests for maintenance services
- Control and evaluate the maintenance activities made through external contracts

Major Problems of the Maintenance Administration

Although the Essential Requirements define a list of responsibilities and administrative controls that must be available at any time, many hospitals do not comply with them. This reality needs to be addressed and corrected as soon as possible. Some of the most common problems are the following:

- In Colombia, clinical engineering is so new that many health professionals do not know what it is.
- In general, only in the tertiary level hospitals are the technical or maintenance units directed by an engineer or other professional. Only a few secondary level hospitals have engineers, with the majority of personnel having low or no technical profiles.
- The Health Ministry determines the salaries of every job in the national health organization. The maintenance staff salaries are so low, and the responsibility so high, that many engineers or technicians work only as outside consultants on specific projects. In many hospitals, the chief of maintenance does not fulfill the requirements for the job.
- Some managers do not understand the importance of the technical activities and do not pay enough attention to them.
- The technical or maintenance unit, when existing inside the hospital's organization, normally occupies one of the lower positions and, as an indirect consequence, the hospital manager does not rely on his maintenance personnel.
- A large chasm divides law from reality. Although the law adequate prescribes technical work, local or temporal circumstances govern inside the hospital. For example, developing a long-term planning process is not possible because the hospital managers want immediate results. These results must be obtained in the normal, three-year period of the manager's tenure in the hospital. For some managers, what could be done after he leaves the position is of no concern.
- In the public sector, it is almost impossible to efficiently manage the financial resources required for maintenance. Equipment should be repaired as soon as possible, but administrative and financial processes dictate different priorities.

- In many hospitals, the technical unit is considered only for maintenance activities; other important tasks, like acquisition of new technology, are done only by the hospital manager and administrative staff. Sadly, the engineer learns of this only when the new equipment arrives.
- In relation to maintenance human resources, the Essential Requirements refer only to the availability of electric or mechanical engineers in the maintenance unit, but availability does not mean that these professionals are required to be on the hospital staff. By contracting, many hospitals avoid the necessity of having their own maintenance unit and, hence, their own engineers. One commonly finds only carpenters or masons at work. Herein lies an explosive situation. Advanced, complex medical device technology demands the attention of a trained, skilled professional. One cannot create such a person in just a few hours.
- Organization inside hospitals normally considers technical activities to comprise only maintenance activities, and does not consider the other important technology management issues, such as the acquisition processes, the evaluation of the equipment's operational costs, and training programs.
- Several Colombian clinical engineers have recently begun to form a professional association, which could be a first step toward solving the problems mentioned above. The clinical engineering association should approach the Colombian Engineers Society, which is the official consultant to the central government, and through this entity, study, analyze, and propose strategies enabling the government to correctly actualize the legislation covering clinical engineering activities. This new association should interface with International Clinical Engineering Associations to raise the quality of its professionals to international standards. (See Ott and Dyro, 2003; Easty and Gentles, 2003; Hertz, 2003; Pallikarakis, 2003; Goodman, 2003; Nicoud and Kermit, 2003; and Grimes, 2003.)
- The National Superintendent of Health must exert better supervision and control to ensure that hospitals comply with every obligation in the norms relating to clinical engineering.

Maintenance Investments

Since 1994, the central government has made some investments through the Health Ministry to help the regional and local authorities to develop maintenance services. These include training programs and acquisitions of tools and instrumentation to update the technology required, in a first step program, to ensure quality control in maintenance services. A \$50 million investment was made through an InterAmerican Development Bank (IDB) loan. The project was made through a Program known as *Mejoramiento de los Servicios de Salud* (Improvement of Health Services) between 1996–1997.

Maintenance Human Resources

In the early 1990s, several Colombian clinical engineers attended several Advanced Clinical Engineering Workshops organized by the American College of Clinical Engineering with the support, in part, of the Pan American Health Organization and the World Health Organization (Dyro et al., 2003). During 1997 and 1998, through the program mentioned above, approximately 23 engineers who worked in the main and more advanced hospitals in the country had the opportunity to take a clinical engineering course designed and developed by The Andes University—one of the most recognized universities in the country—that enabled them to improve their skills and abilities in performing technical work. Other education institutions have begun training programs in the area. During the 1990's, this resulted in trained technicians who gradually were incorporated into hospitals and began to do more technical work than was done in the 1980's. Some of the universities that now offer training programs in bioengineering, electromedicine, clinical engineering, maintenance, acquisitions, supervision, and control of activities are the following:

It is important to know that the increased number of Colombian technicians and engineers who are working now in Colombian hospitals are products of normal training programs of universities and technical schools. Only recently have these new engineers and technicians had the opportunity to begin work in hospitals.

Physical and Functional Hospital Census

Between 1994 and 1998, the Health Ministry, using resources of BID, and through the Improvement for the Health Services Program, made a Physical and Functional Hospital Census that covered 170 public secondary and tertiary hospitals. The census updated all aspects relating to hospital architecture: Physical infrastructure; engineering systems (including water supply installations, mechanical and special installations, electrical and communication installations); and the medical equipment inventory. For each component, a group of architects and engineers designed the required methodologies to gather the information, and systems engineers developed the required software to process the information collected in the hospitals.

The most important results of the census were the following:

- **Architecture.** Every hospital covered has updated architectural blueprints and a detailed analysis of the architecture style and the ways in which the hospital connects with other health institutions and with the community it serves.
- **Physical Infrastructure.** A detailed evaluation of the physical infrastructure of each building from external areas to the interior spaces. All materials used in doors, windows, floors, and walls were classified and their condition, appearance, and maintenance evaluated. Each service and functional unit was counted and classified producing a unique, national classification with updated blueprints of the distributions of services and functional units inside the hospitals.
- **Engineering Installations.** For each type of installation, the Census provided up-to-date blueprints and detailed information of each system, including mechanical installations, electrical and communication networks, water supply systems, fire protection systems, and sanitary sewer systems.
- An **up-to-date equipment inventory** that covered all medium- or high-technology equipment.

Table 21-3 Universities offering training programs on technical subjects

Institute	Area	City
Los Andes	clinical engineering	Bogotá
Francisco José de Caldas (Distrital)	electronic with specialization in electromedicine	Bogotá
Antonio Nariño	biomedical engineering	Bogotá
Manuela Beltran	hospital engineering and biomedical engineering	Bogotá, Bucaramanga
Pascual Bravo	management acquisition processes	Medellín
Escuela Colombiana de Carreras Industriales	electromedicine and biomedical engineering	Bogotá, Cali
Sena (National Apprenticeship Service)	electromedicine, electricity, electronics, machine tools, welding, painting, refrigeration, air conditioning, boilers, out-of-board maintenance motors	Bogotá, Medellín, Manizales, Bucaramanga, Barranquilla, Cali
Sergio Arboleda	hospital architecture and maintenance	Bogotá
El Bosque	electronic with specialization in electromedicine	Bogotá

The information collected by the Census in databases files was delivery to the regional health authorities and to the managers of each hospital. This information enables the hospital staff to improve planning processes and to manage the investments that are required in order to offer health services of the highest quality. This information is also fundamental to maintenance services, and it is the responsibility of the technical team to keep it up to date.

As an example of the information collected, Figure 21-2 shows a national summary of the distribution of equipment of medium- and high-technical complexity by hospital medical and administrative units (Villamil, 1998a). The distribution of medical equipment by functional unit is shown, as well as the convention codes to identify each functional unit. Clinical laboratory and surgical units have the highest concentration of equipment. Such information enables technical departments to define priorities and to plan maintenance actions.

Figure 21-3 contains additional census information. The first graphic contains information about the technological nature of the equipment found; the second, information about the kinds of maintenance services employed; and the third, information on the functionality of the equipment (Villamil, 1998b). It can be seen that electronics is the prevailing technology, followed by electromechanical. This information is important for defining the profiles required by maintenance technicians and engineers working in hospitals. Also apparent is that corrective maintenance (external or in-house) is the most common alternative used in the country, while preventive actions lag far behind. This finding emphasizes the need to develop better preventive maintenance programs to increase the quantity of functioning equipment.

Medical Device and Equipment Technology Legislation

Recently, the Health Ministry signed the Official Resolution No. 00434 (2001/03/27) (MoH, 2001) that defines norms to evaluate and import biomedical technologies and

Brief Resume of the Country

Official name: Republic of Colombia
 National holiday: July 20 (independence Day)
 Government form: Unitary presidential republic; two legislative chambers
 Actual constitution: July 4, 1991
 Population: 40,000,000 estimated year 2000

Capital: Santa Fe de Bogotá
 Geographic location: From 66° 50' 54" Greenwich West Longitude, to 70° 01' 23" Greenwich West Longitude; from 4° 13' 30" South Latitude to 12° 27' 46" North Latitude
 Colombia is situated in the northwestern part of South America and bounded on the north by the Caribbean Sea (1600 km), on the east by Venezuela (2219 km) and Brazil (1645

km), on the south by Peru (1626 km) and Ecuador (586 km) and on the west by Panama (266 km) and the Pacific Ocean (1300 km). Colombia is the only country in South America with coasts on both the Caribbean Sea and the Pacific Ocean.

Total Area: 2,070,408 km
 Terrestrial Area: 1,141,748 km
 Marine Area: 928,660 km
 Political division: 32 departments and a district capital (Santa Fe de Bogotá)
 Largest cities:
 Santa Fe de Bogotá 6,000,000
 Cali 2,500,000
 Medellín 2,500,000
 Barranquilla 2,500,000
 Bucaramanga 2,200,000
 Ethnic groups:
 Mestizo: 58% mixed European and Native American ancestry
 White: 20%

Mulatto:	14% mixed white and black ancestry
Black:	4%
Mixed black and Native American:	3%
Native American:	1%
Urban/rural breakdown	
Urban:	73%
Rural:	27%
Official language:	Castilian (Spanish);
Other languages:	Native American languages (e.g., Arawak, Karib, Chibcha, and Tukano)
Religions:	Roman Catholicism (95%); others (5%), including Protestantism and Judaism
Economy:	gross domestic product (1998) U.S. \$102,896 million

- **Agriculture:** Coffee, sugar cane, bananas, tobacco, cotton, cut flowers, cacao beans, potatoes, cassava, and plantains
- **Mining:** Petroleum, natural gas, coal, nickel, gold, and emeralds
- **Manufacturing:** Food products, textiles, beverages, transportation equipment, and chemical products

- **Employment breakdown:**
Services 46%
Agriculture, forestry, and fishing 30%
Industry 24%
- **Major imports:** Food, machinery and transportation equipment, chemicals, minerals, metals, computers, and electronic and communication equipment
- **Major exports:** Coffee, agricultural products (especially flowers and bananas), petroleum, coal, gold emeralds, chemicals, and textiles
- **Major trading partners:** United States, Venezuela, Germany, Japan, Netherlands, Brazil, and Peru
- **Currency:** Colombian peso (U.S.\$1 = 2350 Colombian pesos -2001)
- **Education:**
Major universities:
National University (Bogotá, Medellín, Manizales, San Andres, Palmira)
University of Antioquia (Medellín);
University of El Valle (Cali)
University of Los Andes (Bogotá); University Javeriana (Bogotá)
University of El Rosario (Bogotá); University of Cartagena (Cartagena)
Eafit (Medellín)

Figure 21-3 Prevailing technologies, kinds of maintenance services, and equipment functioning in Colombia.

Note: The Census detected that there are a total of 10,580 devices that do not receive maintenance services of any kind, and that quantity is 30.11% of the equipment evaluated. For other types of equipment it was not clear if they received any maintenance.

defines the technologies that the authorities must control. The resolution establishes the methodologies and evaluation procedures for technical and economic analysis and methodologies to allocate the technology throughout the country. It also defines the criteria for technology acquisition, importation, and incorporation into the health services, enhancing quality and cost-effectiveness.

The resolution covers biomedical equipment and devices, surgical instrumentation, surgical procedures, drugs, and information systems used in the health services. For the first time, a classification of medical equipment by risk, physical state, and use has been established. The risk classification is based on international risk classifications (high-risk, classes IIB and III; medium-risk, class IIA; and low-risk, class I). The physical state classifies the equipment as like-new (i.e., not used or less than a year from the date of manufacture); old (i.e., less than four years from the date of manufacture); and prototype (i.e., equipment or devices in an experimental stage of development, without authorization to be used to provide health services). Moreover, the resolution defines the process of technological evaluation and finally defines types of controlled technologies, which require a special process to be imported into the country.

Clinical Engineering in Ecuador

Juan Gomez

Director, Hospital Maintenance Division
Ministry of Health
Quito, Ecuador

The Republic of Ecuador, located in the “belt” of Latin America, has an area of 275,830 square kilometers and a population of 12,174,628 (1998 census).

The Ministry of Public Health is the steering agency for health services and manages the largest number of hospital beds in the country, as shown in by level of complexity in Table 22-1 and by number of beds in Table 22-2.

The approximate cost of the equipment for that investment (approximately US\$50,000/bed) is US\$4.35 billion, while \$304.5 million (7%) is required for its annual maintenance. The Ministry of Health’s 2001 budget for hospital maintenance is \$3,212,622, i.e., one-hundredth the amount needed to keep this technology infrastructure in optimal condition and working efficiently, not including physical infrastructure and facilities.

Background

With the oil boom in the 1970s, the country’s physical hospital infrastructure began to be broadly expanded and modernized. In the Ministry of Health, the Department of Hospital Maintenance was created and later transferred to a state agency, the Ecuadorian Institute of Sanitary Works (IEOS), which began providing technical assistance to health care facilities and an ongoing training program for operating and maintenance staff at those facilities nationwide. Technical cooperation agreements were established with PAHO/WHO and friendly governments to train technical maintenance staff.

The 1980s were marked by a national economic crisis that contracted financial resources for maintenance, which led to the rapid deterioration of the health services technology infrastructure. This situation was aggravated by the acquisition of new medical and industrial equipment with technologies that demanded greater financial, human, and administrative resources.

In the 1990s, the country instituted a health sector reform process involving decentralization and modernization of health care facilities. As a result, the IEOS disappeared, and its technical assistance, training programs, and maintenance activities were transferred to the hospitals. Accordingly, in the new millennium, maintenance of the technology infrastructure, particularly infrastructure related to knowledge and the application of clinical engineering, must be developed and adapted to the new role brought on by these changes.

Technology Infrastructure Maintenance Status

In order to establish criteria with respect to the new role that maintenance activities should play in the ministry, it is important to analyze the following related elements:

- Organization
- Medical/industrial equipment
- Human resources
- Budget
- Information

Organization

With the advent of health sector reform, maintenance programs have not been properly defined and identified; therefore, there is no duly structured national maintenance policy. The organizational development of local maintenance systems has been weak; this is further complicated by the presence and activities of unions, as well as low wages, which affect normal operations at the local level. The rise in the market for used and refurbished equipment, as well as greater donations of equipment, is leading to serious operating and maintenance problems, because of the lack of manuals and parts and the absence of regulations and standards controlling the quality and efficiency of these devices. Private-sector involvement in equipment maintenance is inadequate, providing only weak technical service support, due to existing economic constraints and the lack of adequate execution and control mechanisms for such interventions. The lack of coordination

among institutions in the health sector often leads to a duplication of equipment in a single city or region. Some of this equipment is quite expensive, resulting in a waste of the limited national funds available for hospital equipment.

Medical/Industrial Equipment

The mix of brands, models, and origins of existing equipment is an important factor in the inefficient delivery of maintenance services. Approximately 50% of the equipment is out of service, boxed up, or operating poorly. Much of the equipment was manufactured 15-25 years ago and therefore has fulfilled its service life. Physical plant and utility systems have an average useful life of 40 years, with a similar percentage of deterioration. The ongoing adoption of the latest technologies in the area of medical devices places greater demands on medical, operating, and maintenance staff and new demands on sites and facilities. It also generates high operating and maintenance costs. Waste and inefficient use of energy resources such as water, electricity, steam, and medical gases leads to high consumption costs and hence, high operating costs. The lack of hospital safety programs directed at all personnel in medical units often causes problems related to the proper use of equipment and facilities, which affects the life of the equipment and the physical integrity of the people who work with it.

Human Resources

There is a shortage of professional and technical maintenance staff. Approximately 76% of staff have received only on-the-job training; 19% of the staff are technical; and 5% professional. The state-of-the-art technology of the new equipment has not been updated because of the limited professional staff, and there is a lack of human resources in these new technical areas, as illustrated in Figure 22-1.

Since the dissolution of IEOS, there has been no ongoing training program geared both towards equipment operators and maintenance staff, and ministry officials very rarely conduct training courses for such personnel. Universities and polytechnic schools are not involved in training these resources. Mid- and lower-level technical personnel have strong commitments to existing unions in hospital units; this often leads to weak collaboration on attempts to establish maintenance programs in the units. The structural adjustment demanded by the reform process will have a considerable impact on existing human resources for maintenance in each hospital.

Budget

Low percentages of the budget are allocated to maintaining each unit and replacing equipment. Cost analyses are not used as a maintenance management tool. The lack of technical and economic inventories of hospital equipment in each unit makes it impossible to determine real budgetary needs for maintenance and equipment replacement. The budget allotments for maintenance and equipment replacement have historically been based on the number of beds, not real needs. Nonreimbursable loans can be used as a source of financing.

Information

In most hospitals, economic and technical equipment inventories are insufficient. The little information available on equipment is not utilized by management or included in health information systems. There is limited access to the scientific and technical information already available or that could be obtained inside and outside the hospital. Computer systems in each hospital are not sophisticated, and the vast majority of hospitals do not have access to current technologies, such as information networks, e-mail, or the Internet.

New Role

In the new framework of health sector reform, and in the process of acquiring and incorporating state-of-the-art technologies into the health services, the role of engineering,

Table 22-1 Hospitals in Ecuador by level of complexity

Hospitals	No. Of Units	%	No. Of Beds	%
Specialty	2	1.6	700	8.0
Provincial	22	17.5	3,422	39.1
Specialized	13	10.3	2,031	54.2
Cantonal	89	70.6	2,593	29.6
Total	126	100.0	8,746	100.0

Table 22-2 Hospitals in Ecuador by number of beds

Hospitals	Number Of Units	%	Number Of Beds	%
a) More than 200 beds	18	14.3	4,882	55.8
b) More than 100 and fewer than 200	12	9.5	1,531	17.5
c) More than 50 and fewer than 100	13	10.3	840	9.6
d) Fewer than 50 beds	83	65.9	1,493	17.1
Total	126	100.0	8,746	100.0

maintenance, technology management, and equipment regulation programs must be redefined by the following means:

- Strengthening the steering capacity of the Ministry of Health in the area of maintenance
- Organizing and providing training courses, workshops, seminars, and internships that make it possible to train technical equipment maintenance and operating staff
- Developing a new concept of maintenance engineering at both the central and local levels

Factors Involved in This Redefinition

The main factors that will affect the proposed redefinition are the following:

- The deterioration in the physical and technology infrastructure
- New health care delivery modalities
- Changes in the epidemiological profile of the population
- Lack of regulatory programs for medical devices
- The cumulative deficit in maintenance services
- Weak selection processes and the acquisition of technology
- Lack of maintenance service options
- Lack of formal and ongoing training for maintenance staff
- No development of new professional programs
- Development of information technology and communications
- Efficiency, safety, and environmental impact of health care facilities

Purpose

Efforts must be directed toward having a physical and technological health services infrastructure that makes a positive contribution to quality assurance; risk management; and health care facilities accreditation.

General Objectives

The general objectives of health care system restructuring is to develop, operate, maintain, and replace the physical and technology infrastructure in health facilities, to guaran-

tee the delivery of services with equity, quality, efficiency, and safety, in order to protect the investment in this infrastructure.

Specific Objectives

Specific objectives are summarized in the following:

- Undertake an inventory of hospital equipment (technical and economic inventory)
- Strengthen engineering, maintenance, technology management, and equipment regulation policies and programs
- Train operating and maintenance personnel in accordance with the technologies incorporated
- Maximize the use of resources allocated to health facility operations and maintenance
- Improve efficiency and safety in operating the equipment, physical plant, and facilities
- Search for alternatives and mechanisms for delivering maintenance services
- Identify project financing mechanisms

Of these objectives, the following warrant special attention:

- Conducting the equipment inventory to provide a baseline for future interventions for repairs and/or scheduled equipment maintenance and replacement
- Intervention in the different stages of technological equipment management: Planning, procurement, management, evaluation, discarding, and replacement
- Regulating medical equipment and devices and their main activities related to: Registry of entry into the national market; after-sale surveillance; control and inspections of manufacturers and importers; safety, efficacy, and operating evaluation; and standardization of regulatory registries
- Establishment of ongoing training programs

Basic Aspects of Maintenance Engineering

In the new role that Ministry of Health maintenance departments should play at both the central and the local levels, the basic activities that must be accorded priority are as follows:

- Maintenance management: Organizing the departments, employing business criteria to help achieve the basic objective of hospital modernization
- Training: Developing ongoing training programs on the use and maintenance of the technology infrastructure
- Safety and biosafety: Establishing, conducting, and monitoring hospital safety programs that provide for the safe, reliable use of equipment and facilities
- Energy efficiency: training all hospital personnel to properly use energy inputs (e.g., electricity, steam, water, and medical gases) in order to save on operating costs
- Environmental sanitation: Establishing control programs for the unit's liquid and solid waste
- Vulnerability and disasters: Organizing and testing emergency evacuation plans and developing studies on the units' vulnerability to disasters

It should be recalled that the maintenance department is part of a larger engineering process whose purpose is to ensure that the hospital has a continuous, safe supply of equipment that runs efficiently and well, at low operating costs, as illustrated in Figure 22-1.

Activities

The activities required to achieve the proposed objectives are organization, training, information, efficiency and safety, research, and mobilization of resources.

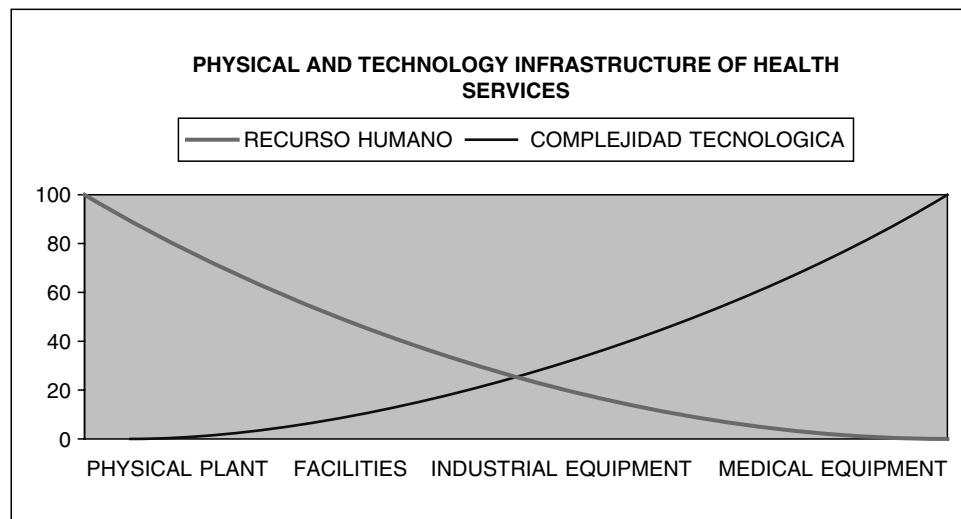

Figure 22-1 Physical and technology infrastructure of health services: human resources and complex medical device technologies.

Organization

- Preparation of national maintenance policies
- Program to regulate medical devices
- Systems for technological management of equipment
- Service maintenance engineering systems
- Programs for preventive maintenance at the local level
- Preparation of codes, standards, and guidelines

Training

- Organization of ongoing training programs
- Internships in technical centers and programs
- Support for graduate students in clinical and hospital engineering
- Technical cooperation with PAHO/WHO and countries in the Americas
- Participation in international congresses and events
- Holding of advanced workshops on clinical engineering

Information

- Technical, economic inventory of medical and industrial equipment
- Organization of management information systems
- Production, compilation, and distribution of technical materials
- Strengthening technical documentation centers
- Links to scientific associations

Efficiency and Safety

- Maintenance management schedule
- Energy resource administration program
- Safety and vulnerability programs in the hospital
- Sanitation program

23

Clinical engineering has developed extensively and rapidly in Mexico over the past two decades. This chapter contains information about the country of Mexico and its health care infrastructure, biomedical engineering education, and clinical engineering activity. The results of a recent survey regarding the practices of hospital based clinical engineering departments are presented. Mexico has a board of examiners for the certification of clinical engineers and a Mexican biomedical engineering society. Finally, the work regarding medical device regulation in Mexico is described, and the challenges that clinical engineers have to face are summarized.

Mexican Health Care System

Mexico is a country of 100 million inhabitants and an area of slightly more than 2 million square kilometers. Unfortunately, almost 40% of the population lives in extreme poverty, although there is an important financial and industrial sector, which supports a middle and upper class. This disparity is reflected in the health statistics (Figure 23-1) that show the causes of mortality to be a mixture of first- and third-world illnesses. Infectious diseases and chronic and degenerative diseases are the major causes of death. Resources need to be allocated to address both ends of the health care spectrum.

Regarding morbidity, the five most important causes are acute respiratory infections, intestinal infections (e.g., diarrhea and amebiasis), diabetes mellitus, high blood pressure, urinary tract diseases, and nutritional deficiencies.

Hospital Infrastructure

Concerning infrastructure (Figure 23-2), Mexico has 21,285 health service units in both the private and public sector. Public sector facilities include 17,496 outpatient care facil-

Summary

Because of new trends toward the modernization of states—particularly in Latin America—that seek to decentralize activities relating to programming, developing, and preserving the physical and technology infrastructure of hospital units in the countries, the individuals who are responsible for preserving such infrastructure, particularly medical equipment, are taking on a new role in their activities.

A technical/economic survey of the current status of hospital equipment, both medical and industrial, must be conducted (equipment inventory) to determine the operating condition of every piece of equipment in each health facility and to schedule the resulting rehabilitation, preventive maintenance, and repair activities; there also must be ongoing training for operators and maintenance staff, using facilities in institutes of higher education and cooperation from international organizations, such as PAHO/WHO, and friendly governments.

National policies on maintaining and resupplying these units must be established, together with programs to regulate equipment and donations, technology management systems for them, and maintenance programs that employ a management perspective, similar to those found in the private sector. The execution of energy-resource administration, hospital safety and vulnerability, and basic sanitation programs plays an important role in this process.

The use of information technology is critical to this management style and is also a source of information for producing, compiling, and distributing technical materials. Research and mobilization of resources must be directed to develop. New maintenance service models, promote operational research, and pursue resources and sources of financing.

When properly managed, all of these elements will make it possible to achieve the general objective of developing, maintaining, and renewing the physical and technology infrastructure of health facilities to ensure equity, quality, efficiency, and safety in service delivery in order to protect the investment in infrastructure.

Clinical Engineering in Mexico

ities, from which just 171 are tertiary or specialized-care hospitals, and 705 are secondary-care general hospitals. In the private sector, 2841 hospitals have fewer than 40 beds, and 72 hospitals—23 of which are in Mexico City—have more than 50 beds.

The Mexican Social Security Institute (IMSS) provides health services to its 40 million participants. The Social Security and Services Institute for Government Employees (ISSSTE) serves 10 million people. The public sector health state services, Health Ministry, Secretaria de Salud (SSA), provides services to another 40 million. About 10 million people are served by the private sector, such as PEMEX, and state services, such as the army and the navy (Figures 23-3 and 23-4).

Technology Problems in Mexico

Almost 90% of all medical device technology is imported. As a consequence of the lack of national production, some of this imported technology is not as efficient as it would be if it were produced in the native country. This increases the costs of health care delivery.

As it is elsewhere in the world, medical technology (i.e., devices, procedures, and drugs) in Mexico is advancing rapidly and constantly. The absorption of this technology by the health care system places an increased burden upon the users, nurses, physicians, and technicians to receive training and to become specialized.

Unfortunately, financial limitations prevent the purchase of all of the equipment, medical devices, and consumables that are needed for all health care units. However, in many hospitals, equipment is underused or is so antiquated that it no longer can be used safely.

Medical equipment is not equitably distributed across the country. The Y2K program showed that 45 % of all electronic medical equipment is in the capital city, Mexico City. Thus, much of Mexico's population does not have access to high technology services as it does not have the means to travel long distances to the city.

Most hospital administrators or medical directors buy state-of-the-art equipment. However, this equipment is not necessarily the most appropriate to meet the needs of each

Mortality Causes

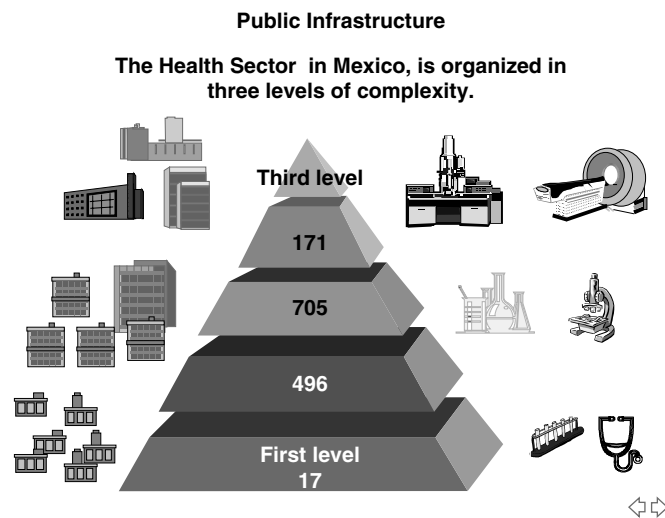

Figure 23-2 Hospital distribution in three levels of complexity in Mexico.

of the health care units. Usually there are not enough financial resources to purchase maintenance or to acquire equipment consumables. In only a few institutions is the technology evaluated extensively before it is purchased.

Biomedical Engineering Education in Mexico

In 1973, biomedical engineering formally started developing in Mexico with a bachelor's degree program at Universidad Iberoamericana. In 1974, another program started at Universidad Autonoma Metropolitana Unidad Iztapalapa. Today, there are four universities offering bachelor's degrees and two offering master's and/or doctoral degrees in Biomedical Engineering. One program that started in the 1960s is dedicated to bioelectronics and research. The four universities are in Mexico City, but now there are three electronic engineering bachelor's degree programs, which have specialty courses in medical electronics or medical instrumentation, in Guadalajara, Morelia, Tijuana, and Puebla.

These programs have produced more than 1000 biomedical engineers who are now working in the following areas:

- In 65 public and private sector hospitals, tending to maintenance, acquisition, training, and use of medical equipment.
- At more than 20 companies, as vendors or distributors of medical technology, providing more professional and informed sales and ongoing support
- In research at more than 10 universities, or in the health sector developing new technologies to better serve the sector
- In information technologies in other sectors

Figure 23-3 Hospital infrastructure in Mexico: Public (SSA 40%; IMSS 29%; ISSSTE 11%; army and navy (SEDENA), SEC MAR 4%, university 1%; and PEMEX 3%) and private 8%.

Biomedical Engineers in Hospitals

In 1978, the first clinical engineering programs in hospitals started. By 1984, four private and five public hospitals had opened clinical or biomedical engineering departments. Today, there are 65 clinical engineering departments working in secondary and tertiary care hospitals; i.e., general care hospitals and highly specialized care hospitals. These cover barely 10% of the need. Where there are no biomedical or clinical engineers, mechanical or electrical engineers and technicians from plant engineering service the medical equipment. These individuals do not have the proper training to manage these health care technology resources effectively, however.

National inventories of medical equipment technology were taken as part of the country's response to the Y2K problem (see Chapter 105). In the course of the inventory, the following were revealed:

- Medical equipment not working properly because of lack of parts or consumables
- Equipment that had not yet been installed because of lack of coordination among maintenance, purchasing, end user, and vendor
- Equipment that was not needed or used
- Lack of medical equipment management programs, which could result in better use of currently available technology in public and private hospitals

A proposal was made for biomedical engineers at regional levels to help with technology management by performing evaluations and general problem solving. Unfortunately, this has not happened yet at a national level.

The results of a Mexican clinical engineering survey made in 2002 show that the 65 clinical engineering departments in Mexico are located primarily in private hospitals with more than 50 beds and at the Health Ministry (Secretaria de Salud) hospitals.

The education of biomedical or clinical engineering department heads is as follows:

- 91% bachelors in biomedical engineering
- 9% bachelors in other engineering fields such as electronics.

Of those surveyed, 9% have a master's degree and 20% have a management diploma.

Within the hospital organization, biomedical and clinical engineering departments report in the following way (Figure 23-5):

- 15% report to the medical director
- 70% report to the management director or hospital administrator
- 15% report to other departments such as maintenance or research

In several hospitals, the clinical engineer coordinates all technological areas and serves as either technology officer, director, or assistant director in charge of the following:

- Biomedical or clinical engineering departments
- Plant engineering (the machine room and all systems including electrical, hydraulic, and pneumatic)
- Electronics, audiovisual, and communications (e.g., networks, phones, fax, copy machines, and audiovisual equipment)
- Systems engineering (clinical and administrative computers)
- In-house maintenance (painting, furniture, signage)
- Laundry and pharmacy
- Special projects like new construction or technology assessment

Monthly salaries are displayed in Figure 23-6. As is evident, no standard salary for biomedical and clinical engineers exists. The low salaries are inappropriate for jobs that entail high responsibilities. Advocacy for higher salaries is a priority. It is suggested that one avenue for salary increases is to tie increased productivity to increases.

The work done in typical clinical or biomedical engineering departments involves the whole cycle of technology:

- Establishing the need for a new technology
- Planning and research on new products and the status of those already in use
- Pre purchase evaluation
- Participating in the acquisition committee (sometimes merely as observers)
- Transferring devices to the hospital location where they will be used
- Verifying the installation
- Coordinating training for technicians, doctors, or nurses, on different shifts, according to the need
- Calling the vendor for service during the warranty period and performing preventive or corrective maintenance with or without the presence of the vendor
- Reviewing safety issues
- Evaluating the performance, productivity, and quality of service rendered
- Replacing planning for old equipment
- Providing consultation on problems and operation, if involved with technology design, development, production, and sale
- Selecting appropriate technology and vendors

The survey data show that clear distinctions among the work of the CE supervisor, CE, other engineers, and BMETs do not exist (see Table 23-1). In some of the hospitals, the work of the BMET job is done by clinical, electronic, or mechanical engineers or students because there is a lack of BMETs.

A survey was made of hospitals with and without clinical engineering departments (CED). It was found that where there is no CED, there is a considerable amount of equipment that is left without service, unless it is urgent or very important to the institution. In public hospitals, the percentages of medical devices at three levels of complexity were as follows: High complexity, 7%; medium complexity, 36%, and low complexity, 57%.

Medical Device Regulation in Mexico

Mexico has five biomedical engineers at the state level making decisions involving medical equipment: one in the federal unit for regulation of medical equipment; at least 20 at the 10 National Institutes of Health; one making medical equipment purchasing decisions for IMSS (which has 40 million participants); two at the Health Ministry in charge of medical equipment central purchases; and four in the Technology Assessment and Management Unit at the Health Care Ministry advising on the e-Health National Program and the cost-effectiveness of certain appropriate medical equipment for special populations. This unit has programs to promote better use of medical technology and a program to regulate donations.

Two biomedical engineers work in the Mexican regulatory agency, COFEPRIS. This federal commission focuses on sanitation and is responsible for the following:

- Sanitation risks evaluation
- Issuance of regulations, authorizations, registrations, permits, and licenses
- Verification of compliance with regulations
- Law enforcement
- Decentralization and wide coverage
- International affairs
- Management and support systems
- National Public Health Laboratory's Net

Clinical Engineering Certification Program

The Mexican Clinical Engineering Group was established in July 1991. This followed the certification of the first Mexican clinical engineer by the International Certification Commission for Clinical Engineering and Biomedical Engineering Technology (ICC) and the first Advanced Clinical Engineering Workshop (ACEW) in Washington, D.C. (see Chapter 70). The Mexican Clinical Engineering group became the clinical engineering chapter of the Mexican Society of Biomedical Engineering in October 1993.

With the support of the ICC and the U.S. Board of Examiners (see Chapter 133), the first clinical engineering certification exam took place in Mexico. Three more Mexicans became certified, and three students passed the first part of the exam. In July 1994, the ICC approved the Mexican Board of Examiners and accepted the affiliation of the Mexican Certification Commission (MCC). The MCC administers the exam in Spanish.

Clinical engineering certification is not a valid license to practice clinical engineering. According to the laws and rules regarding the education of individuals, Mexico does not recognize it as a legal registration. Of primary importance is that certification demonstrates professional achievement and that it is highly regarded by peers in the profession. The clinical engineering chapter of the Mexican Society of Biomedical Engineering provides information regarding certification. The exam has three parts: A general knowledge exam, a written essay exam, and an interview by three proctors. More information is available at the address below:

Mexican Society of Biomedical Engineering

Since 1991 an active group of clinical engineers has been meeting monthly. This group, the Clinical Engineering Club, was later accepted as the Clinical Engineering Chapter of the Mexican Biomedical Engineering Society (SOMIB). SOMIB was formed in 1976 by the first teachers of biomedical engineering. SOMIB now has 450 members, and for 25 years it has presented annual conferences and has published a journal twice per year. Its web site (www.somib.org.mx, ingclinica.somib.org.mx) offers information on events, academic issues, and job advertisements. It has a virtual library, national and international biomedical engineering links, and clinical engineering information. The Biomedical Engineering Society participates in the development of federal regulations and standards. SOMIB has the following ten chapters:

- Diffusion (e.g., web pages)
- Industry, vendors, and distributors
- Clinical engineering
- Academic
- Instrumentation
- International
- Four provinces

SOMIB is a member of several international organizations, including the International Federation of Medical and Biological Engineering (IFMBE) and the International Union of Physical Sciences and Medicine (IUPSM). It is also a member of the Regional Council of Biomedical Engineering in Latin America (CORAL). SOMIB also has memberships in national federations and is a partner of other societies such as the Mexican Hospital Association (AMH) and the Mexican Federation of Scientific Societies (FESOCIME).

Clinical Engineering Challenges in Mexico

Although Mexico started biomedical engineering programs almost 30 years ago, much remains to be done. Some of the priorities are the following:

- To strive for a more financial and academic recognition for technicians and engineers
- To increase the participation of clinical engineers in social security institutions and in the health secretariats of the states
- To have a larger participation in the regulation of medical devices to ensure safe and effective devices commercialized in Mexico
- To promulgate ideas for the improved use of resources
- To demonstrate the importance of selecting appropriate technologies according to specific needs, the cost-benefit ratio, increase technical quality
- To obtain institutional collaboration for the better use of resources, to increase accessibility, equity, quality and efficiency in the Mexican health services to provide better services to the population

Pedro Galvan

Departamento de Mantenimiento, Instituto de Investigaciones en ciencias de la Salud, Asuncion
Paraguay

Health care technology development plays an essential role today in promoting health and developing health systems and services. Traditionally, in developing countries, non-functional equipment and facilities impede the adequate delivery of appropriate health services. Furthermore, a proper equipment management system, which includes health care technology policy, sufficient financial resources, adequate human resources, and a comprehensive maintenance system, is crucial to guaranteeing the development of a sustainable health service.

This chapter provides an overview of the clinical engineering practice in Paraguay and its impact on the care health care technology (HCT) management system for the public health sector. A feasible and sustainable HCT development model is included in the management plan, which is based on a diagnosis of the health care infrastructure that was made few years ago. The HCT management plan focuses on issues such as HCT policy, financial resources, human resource development, and maintenance system to promote a sustainable clinical engineering practice in the country in the framework of an adequate health service delivery policy. Together, a well-structured and organized HCT management with the experiences made in this field can help to establish a comprehensive clinical engineering practice in health care systems.

Introduction

One of the results of globalization and efforts to improve health care systems worldwide has been the recognition that increasingly complex health care technology plays a vitally important role in all health systems.

In the past decade, the majority of countries in the Americas, including Paraguay, have been reforming or considering reform of their health systems and services to promote equity in health and access to health services through improved HCT management (HCTM). Improved HCTM will result in increased efficiency in the allocation, use, and maintenance of resources; improved effectiveness and quality of care; ensured financial sustainability, and encouraging community participation and intersectoral action (PAHO, 1998).

In Latin America and the Caribbean, there are approximately 16,566 hospitals that comprise more than 1,100,000 hospital beds; 44.5% of these hospitals are located in the public sector. Approximately 50% of the medical equipment in public hospitals is out of service or is functioning at a level that is out of compliance with manufacturer safety specifications (PAHO, 1998).

The problem of malfunctioning equipment is complex, however, and it involves issues such as the capital and recurrent cost of equipment; the low level of development of maintenance systems; the lack of standardization; the donation of medical equipment; weak after-sale support service; uncoordinated processes for infrastructure development; a lack of technical capacity; and a shortage of professional and technical staff (75% self taught; 19% technician; and 6% professional) in public sector hospitals.

In Paraguay, the hospital infrastructure lists 1207 hospitals with 6966 hospital beds. Of these hospitals, 68.6% are located in the public sector and comprise 62.2% of the hospitals' beds.

The state of the physical and technological infrastructure in the health sector is similar to that in Latin America. A survey of HCT maintenance practices taken in 11 of the existing 18 regions in the country (Galvan and Isaacs, 1999) showed that 48.9% of existing medical equipment and devices were out of service or malfunctioning, mainly due to a lack of managerial capacity and a shortage of professional and technical maintenance staff.

Finally, as in most developing countries, technology development plays an essential role in promoting health and in developing health systems and services. A well-conceived and well-implemented biomedical or clinical engineering department can make an important contribution to the proper distribution of resources, to the selection of cost-effective technology, to greater efficiency and more effective services, to quality assurance in HCT, and to the facilitation of decision making regarding HCT policy in hospitals and other health care services. This chapter expands the information about the status of clinical engineering in Paraguay and its contribution in improving regulation and the appropriate use and maintenance of HCT.

Diagnosis of the Health Care Infrastructure

As in most developing countries, technological development in the health care system of Paraguay has been based on the transfer of technologies designed for developed countries (PAHO, 1998). In many cases, this technology transfer was incomplete, as it was not adapted to the organizational, economic, social and cultural situation of the country.

In the 1980s and early 1990s, some of the common problems in the health care system were the following:

- Scarcity of many basic technologies
- Excessive and indiscriminate use of expensive HCT
- Lack of policies and standards to regulate the introduction and use of HCT
- Underdevelopment of support technologies
- Inequalities in access to available HCT
- Scarce resources
- A shortage of professional and technical staff (i.e., clinical engineers [CEs] and biomedical equipment technicians [BMETs])

Problems such as a lack of HCT policies and standards; uncoordinated donor programs; shortages of, and inadequately qualified, human resources; and suboptimal managerial capacities are consequences of scarce resources, institutional weaknesses, and insufficient capacity to absorb and maintain new technology in the country (Galvan and Isaacs, 1999).

Regarding the field of HCT and physical infrastructures management, it is common to find that equipment and facilities are frequently out of service or malfunctioning (Galvan and Isaacs, 1999) for various reasons, such as the following:

- Lack of infrastructure, equipment, and human resources for maintenance
- Lack of resource planning and management
- Low efficiency and weak after-sale support service
- Low levels of standardization, leading to a high degree of diversity of equipment and physical plant
- Inadequate training of equipment operators and maintenance technicians
- Lack of managerial and financial capacity to improve HCT maintenance

Survey reports (Galvan and Isaacs, 1996; Galvan and Isaacs, 1997) showed that only 51.1% of basic biomedical equipment of selected health facilities, 10 of the secondary care hospitals (second referral level), and 48 of primary care hospitals (first referral level), were in proper working condition. This situation is a direct consequence of the absence of a maintenance program and shortage of, as well as inadequate training, of maintenance technicians. For performing maintenance in the selected hospitals, there were available only BMETs (13%) and self-taught technicians (87%) but no clinical or biomedical engineers.

Sustainable Clinical Engineering Practice

A sustainable and strengthened organization and structure of clinical engineering departments in the health care services is of vital importance and implies a challenge for all stakeholders and decision makers (particularly for HCT, as its rate of change has increased considerably faster, in recent years, outpacing the evolution in the management and organization of national health care).

To develop a comprehensive clinical engineering practice in Paraguay, the Biomedical Engineering Department of the "Instituto de Investigaciones en Ciencias de la Salud-UNA" (Health Sciences Research Institute) proposed a feasible and sustainable strategy based on survey results (Galvan and Isaacs, 1996, 1997), with the key focus on HCT policy, financing and human resource development, as well as maintenance system development.

The final outcome will only be as successful and strong as the quality of effort and skill applied to the key issues.

Health Care Technology Policy

In December 1994, the Summit of the Americas reaffirmed the interest of the governments of the region in promoting reforms in their health systems that would guarantee equal access to basic health services. The summit charged Pan American Health Organization (PAHO), the International Development Bank (IDB), and the World Bank with organizing a special meeting on health sector in the Americas (PAHO, 1998).

In this regard, and within the framework of transformation of the health sector, the Ministry of Health of Paraguay has been working since 1994 (Vidovich et al 1998) on the reorganization of health systems, including health technology, to achieve a higher level of equity, quality, efficiency, and universal access to health care.

In the past, decisions on new construction, the purchase or replacement of HCT, and the approval of new applications were made through specialists like physicians and nurses but without participation of clinical or biomedical engineers. Consequently, in most cases, it is common to find that, for complex HCT, what was chosen was what is technically possible instead of what is really necessary and useful for each health service (PAHO, 1998). This unsatisfactory situation contributed to inadequate procurement and operational strategies and impacted adversely on the health care system.

In order to improve the overall situation, in particular HCTM health technology assessment (HTA) issues, the Ministry of Health defined a strategy (Galvan, 2001) wherein a basic health technology policy (HTP) is an integral part of its overall national health policy and development plans (i.e., contingency, short-, mid-, and long-term plans).

One essential part of the strategy is the assumed health technology development framework, as show in Figure 24-1, which includes two important components:

1. Health Technology Assessment (HTA) (PAHO, 1998)
2. Technology Management (TM)

In order to guarantee ownership and sustainability of the HTA policy, the Ministry of Health includes all national stakeholders in the formulation and implementation of the policy. In this regard, it created alliances with the following:

- Health sciences research institutes (basic and applied)
- Scientific organizations
- Multilateral organizations
- International agencies

In addition, in April 1996, a meeting of ministers of health of MERCOSUR (the commercial alliance among Argentina, Brazil, Paraguay, and Uruguay) was held to address quality and health care technology.

Since 1997, MERCOSUR has had technical subgroup 11, which is in charge of promoting HCT and HTA issues, among other things. In this regard, the technical subgroup is working on multilateral cooperation, facilitating cooperation with international agencies and networks (e.g., PAHO/WHO, ISTAHC, INAHTA, ECRI, and CCOHTA), identifying relevant groups and national institutions in HCT management and HTA fields, and emphasizing that the clinical engineer is pivotal in the proper implementation of such issues.

More recently, the Ministry of Health of Paraguay began creating a critical mass of personnel trained in HTA methodology and practice (Galvan, 2001) who have appropriate access to national and international information sources.

To establish an appropriate HCT system and its management, the Ministry of Health created an HCT management department with three specific objectives:

1. strengthening policy and programs in clinical engineering, maintenance, technology management, and regulation
2. optimal use of the resources assigned to the clinical engineering and maintenance programs
3. improvement in quality, efficiency, and safety of the operation of equipment, utilities, and physical plant, adapting to economic realities

The HCT management department has implemented the divisions of planning, procurement, and management (see Figure 24-1) to achieve the specific objectives and to guarantee health services delivery with equity, quality, efficacy, and safety, and to protect the HCT investment.

A short evaluation report (Galvan, 2001) showed that the impact of the implementation of the HCT development plan was focused on acceptable improvement of the health care referral system, giving access to curative services with appropriate technology to deliver a basic package of essential diagnosis, treatment, and rehabilitation, with increased delegation of responsibilities at the district level.

Furthermore, viewed from a practical perspective, this preliminary country analysis showed that, over the implementation period of HCTM, the evidence gathered demonstrates that 85% of the contingency plan of the health technology policy for the period 1999-2003 has been achieved with the general improvement in the state of HCT. In general, improvement of planning system focusing on an appropriate HCT system and its management was reached at the Ministry of Health through the implementation of the HCT development plans.

Financial Resources

According to World Bank reports (World Bank, 1996), it is recommended that up to US\$12 per capita is required to comply with current health care demands. The reality of the developing countries demonstrates that such targets are difficult to achieve and that they must make tremendous efforts to comply and meet their health care demands (Heimann et al, 2001).

In the case of Paraguay, the *per capita* spending on health in 1999 was US\$112.9, and the public spending was 7.9% of the gross domestic product (GDP) (Vidovich et al, 1998).

The poor financial resources for public health are mirrored in the area of health care technology, with less than 1% of the overall national health budget dedicated to upkeep and maintenance. Despite this alarming situation, the World Bank and the Inter-American Development Bank (IDB) is financing programs with over US\$77 million to construct and rehabilitate (organization, HCT, and training of human resources) many health care facilities at primary health level for the next five years.

Consequently, the financial needs far exceed the resources available. In order to improve the available financial resources, a process of decentralization with increased delegation of responsibilities at the district level could prove to be one of the key responses.

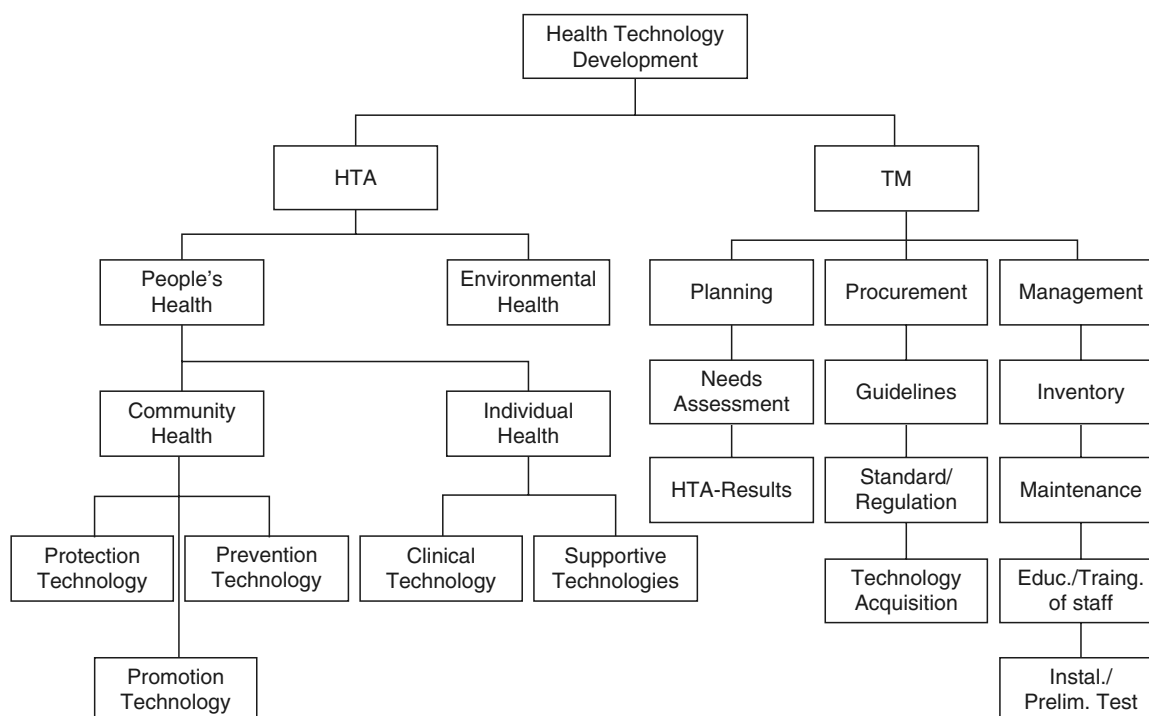

Figure 24-1 Health technology development framework.

Human Resource Development

A sustainable and strengthened HCTM can be achieved only if an appropriate human resource development plan is included in the health technology policy. To establish an appropriate HCT system and its management, human resource availability based on clinical engineers, BMETs, managers, and secretaries as staff members is required.

Such qualified staff should perform activities as listed in Table 24-1 (Bauld, 1987). Task distribution by job classes and the total work effort by all of the staff must be included to account for productivity.

The clinical engineer is the manager of a clinical or biomedical engineering department. The department will be responsible for technology management and at least part of the safety management program. With this variety of responsibilities, several different job roles are required, and each of these may have different educational requirements.

In Paraguay, the main problem with HCTM in the 1980s and 1990s was defined as inadequately qualified human resources and suboptimal managerial capacity. Survey reports (Galvan and Isaacs, 1999) showed that, regarding human resources, the main institutional weaknesses were focused on the following for upkeep and maintenance of HCT:

- Absence of a clinical or biomedical engineer to manage the clinical engineering department
- Shortage of technical staff (2.5% CE, 13% low-qualified BMET, and 84.5% self-taught)
- Inadequate training of maintenance technicians
- Low managerial capacity
- Lack of staff in new technical areas

To improve the HCTM and, in particular, human resource development, a training strategy for BMET and CE was defined. Additionally, another key goal of professional development will be the formation of certification programs for CEs and BMET, with the cooperation and support of the American College of Clinical Engineering (ACCE) (see Chapter 130).

Regarding the training of BMETs, a two-year polyvalent basic training program will be instituted at the National Institute of Health of the Ministry of Health. Such qualified staff should receive further one-year training on medical electronics of biomedical equipment to enable them to fulfill their roles.

The clinical engineering training program includes a five-year polyvalent training at the Polytechnics University of Asunción. Furthermore, a one-year training practicum at hospitals (in clinical engineering departments) or in industry is necessary to enable the clinical engineers to fulfill their roles.

Regular, continuous training courses for staff and clinical equipment users should be implemented, and career opportunities should be explored. Furthermore, specialized courses have been designed and instituted for specific topics, e.g., X ray, CT scanners, lab analyzers, surgery equipment, and ventilators in the annual training program of the Ministry of Health with the cooperation and support of the Senior Experten Service (SES) of Germany.

Moreover, managerial skills are also required at the administrative level (Ministry and Regional Administration) to comply with the needs of a maintenance system and future advances and developments in HCT.

Maintenance System

Maintenance infrastructure should be designed and established at all hospitals and reference centers that have at least 100 beds. Then, in general, at this level there are operating theaters, intensive care units, radiology departments, maternity services, and functional laboratories, all of which need in-house maintenance services.

In Paraguay, the maintenance system situation is similar to that in Latin America. Survey reports (Galvan and Isaacs, 1999) showed that 48.9% of the existing medical equipment and devices of selected hospitals were out of service or malfunctioning, and that one of the main reasons for this situation was lack of infrastructure, tools, equipment, and information systems for maintenance.

To overcome this situation and to improve the HCT maintenance system in the country, the Ministry of Health has designed, and is seeking financial resources to implement,

an HCTM Network for national hospitals as well as all regional/district hospitals as reference centers. The HCTM Network comprises a central workshop, located in Asunción; three regional workshops distributed according to the demand of the involved hospitals in main provincial towns; and three mobile workshops to maintain hospitals in rural and remote areas.

According to the assigned capabilities, the HCTM network should cover up to 85% (depending on volume of complex repair) of the daily scope of maintenance activities. Further, the more complex repair and maintenance work (15%) should be performed by private services (i.e., manufacturers and agents). However, to achieve an acceptable level of efficiency in the HCTM system, a good collaboration should exist among the administration, hospital managers, and workshop personnel.

Recommendations

Clinical engineering departments should be installed close to the problem areas in a sustainable and cost-effective manner. This implies that such departments must have competent human resources (CEs and BMETs), adequate infrastructure, sufficient financial resources, and adequate management for the scope of responsibilities. Furthermore, such departments would not be available at rural and remote levels, given the lack of critical mass of HCT. In Paraguay, the majority of rural and remote hospitals have between 5 and 20 beds, with a lack of critical mass of HCT. To compensate for the absence of such departments in rural and remote areas, the use of mobile workshops incorporated in to the clinical engineering maintenance system is recommended.

In order to achieve a well-organized and well-structured clinical engineering department, an HCTM plan developed according to the criteria of the Joint Commission for Accreditation of Healthcare Organizations (JCAHO) called "equipment management" (EM) should be established to comply with the HCTM's mission and vision.

Conclusion

Clinical engineering practice in Paraguay does not differ significantly from the practice made in other Latin America countries. Proper HCTM, including performing maintenance, is crucial for adequate health service delivery. But local settings differ from region to region in the same country, and appropriate solutions are not easy to find.

In order to guarantee health service delivery with equity, quality, efficacy, and safety, and to protect the physical plant investment, governments need to improve the availability and management of HCT at hospitals in rural and remote areas for the more deprived population.

Sustainable maintenance systems at an affordable cost contribute substantially toward improving the health system. The establishment of an adequate HCT policy, improvement of financial resources, investment in local human resources, and alliances with relevant groups and national institutions to create common positions to solve problems are of vital importance to guarantee a sustainable system.

World experiences show that in-house maintenance services at the local, regional or national level can save the scarce financial resources if driven by a clinical engineering concept and cost-effective considerations.

Investment in continuing education courses for clinical engineers and BMETs is important but is only beneficial if the other key components like sufficient financial resources, adequate infrastructure, and appropriate supply of spare parts are available.

In conclusion, well-structured and well-organized clinical engineering departments to manage and maintain health care technology are absolutely necessary at health care facilities where a critical mass of HCT and utilities is available.

Clinical Engineering in Peru

Luis Vilcahuaman

Coordinador Bioingeniería, Pontificia Universidad Católica del Perú
Lima, Peru

Javier Brandán

Jefe de la Unidad de Bioingeniería, Pontificia Universidad Católica del Perú
La Victoria-Lima, Peru

The attempts at organizing maintenance service in the health facilities of the Ministry of Health in Peru have been rather varied. Within a very general historical framework, some of the efforts made are enumerated here:

Maintenance Service—1966

The proposal, *Organizing the Maintenance Service of the Hospitals of the Ministry of Public Health and Social Welfare of Peru*, was presented as Item X of the Technical Meeting on Hospitals, held in Lima in December 1966. It called for information on the current state of the maintenance service of Ministry of Health hospitals and health centers; planning of what the service should be in the hospitals, including the aspects of staffing, repair shops, standards, preventive and corrective maintenance, safety, costs, performance, links with other services; and recommendations for the creation of a national Office for Maintenance Supervision.

The presentation to the participants concluded with a proposed Organizational Chart for the Maintenance Service, in which the chief of maintenance reports to hospital management, and a Table of Economic Resources comparing health care facilities in the country.

It is important to recognize the conceptualization of maintenance, as well as its proposed organization, at that time. Also deserving of special attention is the establishment of the category “economic resources for maintenance” as a specific line item for maintenance activities.

However, this proposal was implemented in just one or two hospitals in the country, and only as a result of its author’s tenacity. There was no continuity in this process.

National Plans for Coordinated Action in Health (PNACS 82/85)

National Plans for Coordinated Action in Health (PNACS 82/85) was implemented in 1981, with financial support from the World Bank, with the purpose of developing the National Health Services System. Here, it is worth mentioning the comprehensive vision of the health services linked with the maintenance services.

The pyramid of care in health services formulated by this plan consisted of four levels parallel with the maintenance service, as follows:

<i>Care in the health services</i>		<i>Maintenance services</i>	
1st Level:	Community Shelter Health post Health center	1st Level:	Maintenance Re-equipping Remodeling Increase
2nd Level:	Local hospital	2nd Level:	Maintenance
3rd Level:	Regional hospital		
4th Level:	Highly specialized Hospital		

This national plan remained only in the study phase, and its maintenance provisions were never implemented.

National System for the Maintenance of Physical Health Services Infrastructure May 1983

This proposal was presented at the first Meeting on Health Services Architecture and Engineering, which was held in Lima from May 2–10, 1983. It began with an overview of the state, as of 1983, of the Office of Maintenance and Reequipping (OMR), organized into the following units: The Medical Equipment Unit, consisting of the following departments:

Electromedical, electromechanical, dental, diagnostic imaging, and telecommunications; the Heavy Equipment Unit, consisting of the following departments: Boilers, electrical generators, general services, and sterilization; the physical plant unit, consisting of the departments of civil, sanitary, and electrical engineering; and the Agreements Unit, for the reequipping to be done during that period. It is important to note that at that time, the OMR had staff with different levels of training: 47 professionals (14 with university degrees, 33 with high school diplomas), 82 technicians, 126 auxiliaries, and 50 service people, for a total of 260.

The proposal itself rests on three supports: Research and norms, training, and economic resources for the purpose of conducting a situational diagnosis, post analysis, and operations research on the demand for services, and designing the maintenance system.

As in the preceding case, this proposal did not obtain the necessary support from the decision makers in the Ministry of Health.

Consultancy on a National Maintenance System

The purposes of the Consultancy on a National Maintenance System provided to the Ministry of Health of Peru 15.10.83–15.12.83 were to design the National Maintenance System, to prepare a complete timetable, and to detail the process, as well as the scope, of each activity involved in the development of the Maintenance Plan, based on the established criteria.

This work concluded with the following recommendations:

- That the Pan American Health Organization/World Health Organization (PAHO/WHO) continue its support of the Ministry of Health of Peru to implement a Maintenance System that is more complete and efficient than the existing one.
- That PAHO/WHO participate and actively collaborate in a plan to present the social and economic benefits of programmed maintenance, geared to directors of hospitals and offices that support the senior management of the Ministry of Health, indicating indexes and the proportion of capital required by the maintenance.
- Insofar as possible, ensure recognition of the financial burden represented by hospital maintenance for governments such as that of Peru, since the country does not produce hospital equipment.
- That a permanent commission be established to execute the activities according to the approved timetable of the National Maintenance Plan.

In fact, practical action was never taken to establish a maintenance system; thus, this work remained in the consultancy phase.

Situational Diagnosis of Maintenance Services in the Hospitals of Metropolitan Lima, 1984

Situational Diagnosis of Maintenance Services in the Hospitals of Metropolitan Lima, 1984 was conducted by the Office of Physical Infrastructure of the Ministry of Health, under the project known as Development of the Physical Infrastructure of the Ministry of Health (DIF), with joint support from the United Nations Development Program (UNDP) and the Pan American Health Organization (PAHO). This project lists, in the form of technical files, the hospital services, organization of maintenance, ratio of maintenance staff, and area available for maintenance shops. This diagnosis did not lead to concrete results in terms of changes in the country’s maintenance system.

National System for the Rehabilitation of Infrastructure and Equipment (June 1986)

The National System for the Rehabilitation of Infrastructure and Equipment (June 1986) was sponsored by the National Service for the Rehabilitation of Infrastructure and

Equipment (SENARINEO) and with the knowledge of the German GTZ Project, described below, which defines the above-mentioned National System with three levels:

1. Central level: Regulates, supervises, provides technical assistance, serves as controller, and administers the system at all levels, requiring multidisciplinary, specialized human resources
2. Intermediate level: Responsible for providing services to rehabilitate infrastructure and equipment; it would consist of technical service centers (TSCs) throughout the country, which would have material resources, specialized technical personnel, and rehabilitation workshops
3. Local level: Made up of the maintenance departments of hospitals and health centers, and workers in general

This system was not implemented, despite a ministerial resolution to create 12 technical service centers in the country.

Hospital Maintenance Service Project—Ministry of Health (Mds) and German Technical Cooperation Agency (GTZ), 1982–1994

The Hospital Maintenance Service Project was implemented under a technical cooperation agreement between the Republic of Peru and the Federal Republic of Germany (D.L. No. 21086 of 28 January 1975), based on the previous experience of the German government, in which loans had been made for the construction of new hospitals during the 1960s and 1970s. However, because of ignorance about the concept of maintenance and the activities related to it, the infrastructure, facilities, and equipment deteriorated prematurely; new loans therefore were requested for the construction of new hospitals, or in their absence, for the purchase of new equipment, without considering the necessary expenditures for maintenance of the investments already made.

The first period, 1982–1987, had the following goals:

- Establish a Training Center for Health care Facilities Maintenance Technicians in the city of Chimbote (currently named CENFOTES)
- Establish a regional center in Chimbote to offer maintenance services to hospitals belonging to the former Health Region IV: Ancash-La Libertad (at the present time, the technical service center (TSC), located at the Hospital de La Caleta in Chimbote, is not in operation)
- Promote short training courses in hospital equipment maintenance.

The second period, 1987–1988, was marked by donation from the German government:

- Acquisition of heavy equipment, tools, vehicles, and photocopying machines for four technical service centers (TSCs) in Puno, Cuzco, Huancayo, and Chimbote
- Acquisition of heavy equipment and tools for five regional hospitals: Iquitos, Tarapoto, Trujillo, Chiclayo, and Ayacucho.

The third period, 1989–1993, had the following goals:

- Develop logistic system to supply parts and materials for maintenance
- Reorganize the administration of maintenance
- Establish a technical information system
- Upgrade the education and training of staff involved in the maintenance and operation of equipment and facilities
- Set up a planning preventive maintenance system (PPM)

The project's goals were not fully met, due to a lack of commitment of Ministry of Health authorities, especially the programs involved with maintenance at the national level, namely: The Office of Physical Infrastructure (OIF); the Office of Maintenance and Reequipping (OMR); the National Investment Service (SNI); the National Service for the Rehabilitation of Infrastructure and Equipment (SENARINEQ); and the Bureau of Equipment Conservation (DIRECONEQ). All of them today are under the National Maintenance and Equipment Program (PRONAME), which translates into the fact that the project had an official national counterpart for only six months throughout the entire period.

In 1991, as the result of an evaluation sent by the headquarters of the German Technical Cooperation Agency (GTZ), which reported little progress in the programmed activities, the project was deactivated and its remaining economic resources reoriented to providing support for the hospitals of the southern region of the country; e.g., a donation of boilers and the piping system in Tacna and Arequipa.

Hospital Management: The Hospital as a Business

The traditional concept of the hospital, understood as a place where people go to heal, and as a result, where only physicians, nurses, and drugs are found, is used increasingly less, as there is a better understanding that the hospital is a conglomeration of human, material, and technology elements, adequately organized through effective management to provide health services (preventive, curative, and rehabilitative) with maximum efficiency and reliability and optimal profitability.

It is these criteria that govern the concept of the hospital as a business, where management (i.e., the rational use of the available economic, physical, human, and technology resources) occupies a pre-eminent place within the health institution in which it is found. This is why we stated at the beginning of the study that hospitals and, in general, the different types of health facilities, either public or private, will tend to manage their resources on the basis of the variables that influence the production of services—either to boost productivity in the case of public facilities, or to boost profits in the case of the private sector.

The Sphere of Maintenance

As stated above, in this study we introduce the modern concept of the business, where the structure of production costs is increasingly a concern. This is why it is of supreme importance to try to minimize costs in order to ensure greater profits. This criterion is employed to the utmost in the competitiveness business model, where the five major pillars of the business environment are the following:

1. Strategic planning in management
2. Quality systems
3. Monitoring and administration of energy
4. Management of maintenance
5. Staff development

As a result, it is clear from the beginning of the study that the management of maintenance is not an island in the complex organization of the Ministry of Health and the health sector in general. Thus, high levels of interaction are needed in order to achieve the great objective of viewing the hospitals of the Ministry of Health and of the health sector in general as businesses, whose objective of providing health care services should be measured by their quantity and quality.

Definitions of Maintenance

Maintenance is the complex of activities carried out to keep goods or property (e.g., real estate, furniture, equipment, facilities, and tools) in efficient, economic, and safe operating condition. The technical objective of maintenance is to have the goods when and where they are needed. The economic objective is to contribute to the less costly production of goods or services within the business. Hospital maintenance, in turn, has an additional objective, known as a "social objective," which is to prevent death or a worsening of illness when hospital goods are in sound condition, the product of adequate maintenance.

The two types of maintenance defined at the beginning of the study are the following:

1. Preventive maintenance: Actions taken as a result of planning rather than demand
2. Corrective maintenance: Actions taken as a result of demand rather than planning

In principle, predictive maintenance (which is an extension of preventive maintenance) has been discussed, as the need for having diagnostic equipment and adequate computer systems would not correspond to a reality like that of the Ministry of Health. The same holds true for the criterion for rehabilitation or refurbishing, which corresponds to activities outside the maintenance budget (such as investment), but within the sphere of maintenance, which will be described under the heading of "economic resources."

The Management of Hospital Maintenance

By the very nature of its actions, which involve hospital goods and human, economic, physical, and technology resources, the management of hospital maintenance has ceased to be viewed as a complex of technical staff, tools, and parts. It is now seen as a group of activities supported by the four major pillars listed below, requiring a manager who makes rational use of these resources:

1. Administration
2. Economic resources
3. Physical resources
4. Human resources

The Maintenance Organization

With a view to establishing a maintenance organization within a modern concept of management, consideration should be given to the following components:

- Maintenance objectives, which will relate to a reduction in deterioration rates, increases in the availability of equipment, reduction in the high operating costs, and increases in effectiveness and production, which together contribute to an improvement in health service delivery
- Maintenance policies, understood as the intention of achieving the objectives in specific periods, known as the short, medium, and long term
- Structuring and execution of the system, defining the functions and location of each system component and prioritizing the criteria for decentralization and autonomy
- Administration, including the criteria for organization, planning, programming, execution, supervision, and control of maintenance activities

In order to achieve the proposed goals of health facility maintenance and to increase production in the services provided, the health facility itself must have adequate infrastructure, facilities, and equipment, as well as repair shops, tools, and parts for maintenance, supported in both cases by sufficient human and economic resources to achieve the optimal levels of care for users of the health services.

Social Security System

While all public hospitals have departments of maintenance and general services, that operate today in Level IV hospitals at the secondary level of management on the Organizational Chart, the first bioengineering unit in Peru was created by general management resolution on May 12, 1995 in the Hospital Guillermo Almenara Irigoyen (Peruvian Social Security Institute, known today as EsSalud). This unit operates in accordance with its manuals on organization and functions and on norms and procedures.

Emphasizing that clinical engineering and technology management represent the administrative structure in the organization of the unit, their human resources are limited in num-

ber but have levels of specialization and training that are consonant with the master's level in biomedical engineering. Since its creation, the unit has focused on providing training and assistance in the technology aspect of critical area equipment, as the effort to change a years-old system, with all its inherent external and internal problems, has produced conflict with various interests. Accordingly, our current strategy and policies focus on education at the different levels, with priority given to the goals of clinical benefit to the patients that will result from the fulfillment of institutional programs and policies.

By way of background, during its first year of existence, our unit established internships that were initially intended for residents specializing in anesthesiology, but currently they encompass five specialties. The following year, we were successful in instituting a bioengineering course within the graduate specialty of intensive care medicine at the Universidad Nacional Mayor de San Marcos.

In an effort to consolidate our status as an organization, the Project for Strengthening the Bioengineering Unit was introduced in 1997, supported by the Office of International Cooperation of what was then the Peruvian Social Security Institute (IPSS), and the Representative Office in Peru of the Pan American Health Organization (PAHO/WHO).

That same year, a cooperative agreement was signed between the Pontificia Universidad Católica del Perú and our hospital in the area of bioengineering.

Since the signing of the agreement, the joint studies that have been conducted include the following:

- In the field of electromagnetic interference, a study of the prohibition of cellular telephony in critical areas of public hospitals (1998)
- Energy saving: A study of the distribution and diagnosis of oxygen loss in the Hospital Guillermo Almenara Irigoyen (1999)
- Warning and advice on the Y2K computer problem (PIAS) (1999)

Apart from the agreement, our staff support the research group GIDEM, also connected with the Universidad Católica. The principal tasks of this group of professionals are technology research, development, and innovation, with the fundamental objective of educating human resources in order to achieve a multiplier effect for the benefit of the country. Also noteworthy are the awards won by staff at the national and international levels.

26

Clinical Engineering in Venezuela

Ricardo Silva

The Pennsylvania State University
State College, PA

Luis Lara-Estrella

Simon Bolivar University
Caracas, Venezuela

The Bolivarian Republic of Venezuela is a federal nation organized into 23 states and a district capital. It has an area of 916,446 square kilometers with an estimated population of 24,169,744, 85% of whom live in urban areas. Life expectancy for the period of 1995-2000 was 75.7 for females and 69.9 for males. These and other health care-related data may be found on the Internet (OPS-OMS Venezuela: "Análisis Preliminar de la Situación de Salud de Venezuela," <http://www.ops-oms.org.ve/site/venezuela/ven-sit-salud-nuevo.htm>).

According to the Constitution of the Bolivarian Republic of Venezuela (Constitución de la República Bolivariana de Venezuela, Artículo 83), health care is a fundamental social right, and the government has the obligation to guarantee it. In order to do this, there is a National Public Health System, controlled by the Ministry of Health and Social Development, based on the principles of free service, universality, integrity, equity, social integration, and solidarity (Artículo 84). Finally, the constitution states that financial support for the National Public Health System is a responsibility of the state (Artículo 85), and that everyone has the right to social security as a public, nonlucrative service that warrants health and protection against different contingencies (Artículo 86).

There are 296 public hospitals; 214 of which are integrated into the National Public Health System, and the rest are integrated into several different public organizations. There are 344 private hospitals, of which 29 are nonprofit organizations. By the year 2000, there were 40,675 hospitalization beds integrated into the National Public Health System (17.6 beds per 10,000 inhabitants), with more than 50% of those in the five most developed states (<http://www.ops-oms.org.ve/site/venezuela/ven-sit-salud-nuevo.htm>).

Origins of Clinical Engineering

The first attempts at organizing clinical engineering-related activities were begun during the 1960s, when the Centro Nacional de Mantenimiento (National Maintenance Center) was created within the Ministry of Health with a grant from WHO-PAHO (VEN 24/U.N.D.P/P.A.H.O.-4862) (Lara-Estrella, 1991). This center was a pioneer in the development of maintenance standards and guidelines for hospital engineering in Latin America. Although it was a good start, the economic welfare of the nation was about to change, and these initiatives were short-lived.

During the 1970s, Venezuela had an impressive economic boom; oil prices were high, and the government had money to spare. The money seemed limitless, and everything could be acquired new. Major investment projects were begun, new hospitals were built, new equipment was bought, everything was overpriced; and there was a lack of government control to avoid excess. At this time it was felt that there was no need for maintenance.

Therefore, maintenance organizations were dismantled and clinical engineering was considered unnecessary.

The National Maintenance Center was the basis for what later became known as the Dirección General de Mantenimiento de Infraestructura Física y Equipos (DIFE) (General Direction for Physical Plant and Equipment). DIFE's functions were planning, construction, and maintenance of the physical plant and equipment for all of the institutions within the Ministry of Health. In 1987, in conjunction with DIFE, the Fundación para el Mantenimiento de la Infraestructura Médico-Asistencial para la Salud Pública (FIMA) (Foundation for Maintenance of Medical Infrastructure for Public Health), was created. FIMA was created with the aim of organizing and optimizing the response time for the maintenance of medical infrastructure and equipment. The headquarters were located in Caracas, but FIMA had offices in each of the 23 states. FIMA was a civil nonprofit organization, overseen by the Ministry of Health, with direct income from the central government (Lara-Estrella, 1991).

Both FIMA and DIFE were centralized structures in charge of all of the technological responsibilities for the whole country. The area of competence for the first one was hospitals, while that of the second was small clinics and ambulatory care units. These organizations selected and acquired technology, determined technical specifications, provided maintenance, installed equipment, and supervised service contracts. This proved to be a great failure because acquired equipment did not necessarily respond to a real technological need; response time for repair of damaged and defective equipment was high; and preventive maintenance was almost nonexistent. Moreover, the amount of corruption in both these institutions was high, and customer (hospital clinical personnel) satisfaction was very low.

Redefining Clinical Engineering

Since 1976, clinical engineering has been studied at the Simon Bolivar University (USB) as part of the bioengineering studies program; however, it was not until 1996 that clinical engineering activities were established in a Venezuelan hospital. Clinical engineering is commonly associated with the management of medical equipment, while hospital engineering concerns with the physical plant. In Venezuela, this distinction of activities was impossible because many of the equipment-related problems are the direct result of physical plant problems and vice versa. Therefore, in 1997, Mijares and Lara-Estrella redefined clinical engineering for Venezuela as "the sum of all the engineering and management processes that, as a whole, allows the optimization of the hospital's technological aspects, guaranteeing an overall efficient technological management, with high

Traditional Hospital Organization

Modified Hospital organization

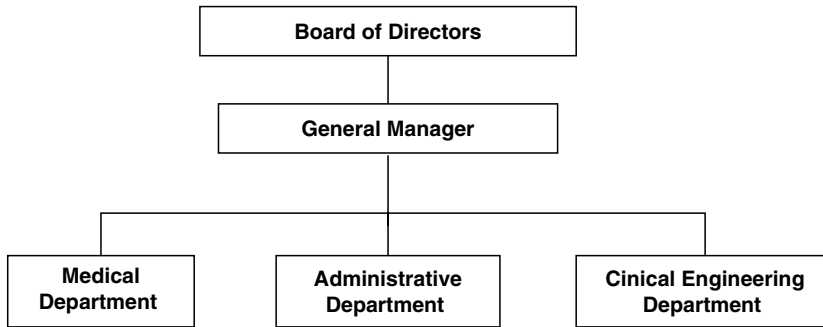

Figure 26-1 Traditional and modified hospital organization models. Under the traditional model, technology management is nonexistent. Consequently, decisions concerning technology are not normally considered within the hospital's management. The new proposed structure includes clinical engineering, in which the technological aspects of health services are considered fundamental elements, due to their important impact on health attention costs.

availability and to the satisfaction of physicians, paramedics, and patients" (Seminario and Lara-Estrella, 1997).

In 1996, the masters program in biomedical engineering was established within Simon Bolivar University and the Unidad de Gestión de Tecnología en Salud (UGTS) (Health Technology Management Group) was created to provide research and funding for clinical engineering-related activities. That same year, a technical assistance agreement was signed between the Simon Bolivar University and the J.M. de Los Ríos Children's Hospital. The objective of the project was to endow the institution with an integral technological management system through the establishment of a clinical engineering department that allowed effective management of all technology available in the institution (Seminario and Lara-Estrella, 1997). The project was begun in March 1996 and lasted ten months. A new organizational structure that considered the technological aspects was proposed. Consequently, the clinical engineering department, structured at a staff level, modified the traditional organization of the hospital in the following way (Figure 26-1).

Successful Implementation of Clinical Engineering

As a consequence of the installation of the clinical engineering department in the Children's Hospital, a generalized increase in productivity could be verified. For example, before the establishment of the department, the hospital generated monthly financial resources of about US\$5263; nine months later, this amount rose to US\$31,578, essentially due to the fact that most of the hospital's installations and equipment were operative (Seminario and Lara-Estrella, 1997). This project went on for several months, but a change in the political scenario brought the project to an end by September 1997; however, the basis was established and the door was opened for new projects to follow, and the modified hospital organization structure (see Figure 26-1) proved to be the most efficient way of addressing technology management.

Two years later, in 1998, Centro Médico Loira, a private hospital in the city of Caracas, requested the establishment of a clinical engineering department in a way similar to that of the Children's Hospital. There were some major upgrades in this project. A mechanism for the evaluation of progress was established, and the concept of the final user was incorporated into the objective of clinical engineering. Clinical hospitality was incorporated as an essential part of the clinical engineering department (Bylaws of Hospitality Financial and Technology Professionals, <http://www.hftp.org/>). In our case, clinical hospitality could be defined as the management of infrastructure and accommodation in order to increase customer (patients, medical doctors, and staff) satisfaction, within a clinical/hospital environment. This concept proved to be significant improvement in clinical engineering management, as technical priorities do not necessarily improve customer satisfaction, and a dirty hospital does not provide a favorable impression even if it has the best medical-imaging department. Thus, taking into account the technical aspects, as well as the hospitality issues and splitting the difference, simultaneously improves clinical practice and customer satisfaction.

Centro Médico Loira's project was a success, and its clinical engineering department has been working ever since. The hospital has steadily been growing, customer satisfac-

tion has increased, and the image of the hospital has improved from a second-level hospital to one of the best private hospitals in Caracas. Following Centro Médico Loira's example, some other private hospitals in Venezuela also adapted and incorporated the concept of clinical hospitality into their technological management.

Nationwide Networking

In 1999, a project was begun to establish a clinical engineering department within Hospital Militar, Dr. Carlos Arvelo, the major military hospital. This project incorporated training of a clinical engineering staff to serve as clinical engineers within the other military hospitals and introduced the concept of clinical engineering networking and coordination at a national level.

That same year, the Ministry of Health decided to change their Technology Management Practices and Procedures, and a New Technology Management General Direction (TMGD) was created within the Ministry. FIMA and DIFE were disassembled, and their technological, and some human, resources were incorporated into this new structure. The purpose of this new structure is to become a policy manager and supervisor of Good Clinical Engineering Practice and to transfer operative processes to the regional level. The TMGD will be responsible for establishing and controlling usefulness, accessibility, and quality of new technology introduced into the country, and for supervising regional activities. However, the operation of technology needs assessment, maintenance, and operative procedures will be managed locally by clinical engineering departments created in every hospital. Simon Bolivar's Health Technology Management Group was hired by the Ministry of Health to manage the transition to the new Health Technology Management scheme. Today, personnel are being trained, structures are being created or modified, and policies are being discussed. If everything goes well, by the year 2004, there should be an organized Health Technology Management network within Venezuela's public hospital system. All of the major hospitals should have a Health Technology Management Department, and the central government should have with a structure responsible for coordinating and integrating technological policies and managerial practices. This should provide the country with the tools required to maintain and improve a quality health initiative within the Venezuelan public health system.

Clinical Engineering in Japan

Hiroshi Kanai

Institute of Applied Superconductivity,
Tokyo Denki University
Tokyo, Japan

This chapter will address the clinical engineering system and national certification of clinical engineering technicians (CETs) in Japan. The present medical device management situation, the challenges that clinical engineering faces, and the Clinical Engineering Technician laws of Japan are discussed.

Clinical Engineers and Clinical Engineering Technicians in Health Care

Various kinds of sophisticated equipment and apparatus have been applied to modern medicine in many countries. Such sophisticated medical equipment should be managed by specially trained personnel who work alongside physicians and nurses. The need to appropriately apply such medical devices has given rise to the need for new members of the health care team, the clinical engineer (CE) (Bauld, 1991; Bronzino, 1995), the biomedical equipment technician (BMET), and the clinical engineering technologist (CET). CEs are specially educated and trained engineers who manage and otherwise support medical device technology in most hospitals in the Americas and in European countries. (See Chapter 15.) Biomedical equipment technicians (BMETs) and clinical engineering technologists (CETs) work in clinical fields such as open heart surgery, hemodialysis, patient monitoring, and assisted ventilation, and perform maintenance and inspection of a wide range of medical devices. Modern health care, with its increasing use of a wide range of medical devices varying in all levels of complexity, has come to rely upon an efficient and effective technology management system to ensure that this technology is safe and cost-effective. Such a system depends upon the contributions of engineers and technicians working in harmony.

In 1991, the World Congress on Medical Physics and Biomedical Engineering met in Kyoto, Japan, and one of the most important subjects was clinical engineering. The topics featured in the clinical engineering sessions at the Congress were the following:

- Clinical engineering role
- Clinical engineering finance
- Clinical engineering technicians
- Education and career of CEs and CETs
- Standards and regulations
- New technologies and their impact on clinical medicine
- Clinical engineering programs in various countries
- Clinical engineering in developing countries

Ten years have passed since the Congress, but most of the problems discussed there have yet to be solved.

Present State of Clinical Engineering in Japan

Japan has only 130 CEs—30 who manage clinical engineering departments and teach clinical engineering in hospitals and 100 who perform clinical research and development of clinical equipment. Japan has about 16,000 CETs certified by the Japanese government. Most work in hospitals, where 2000 maintain clinical equipment, 12,000 operate clinical equipment, and 500 repair clinical equipment. Others work for medical device manufacturers. The current number of paramedical personnel working in hospitals who operate and maintain medical devices is estimated to be about 15,000.

In Japan, clinical engineers who work in clinical research and academia are considered not to need certification. Moreover, only clinical engineers who manage clinical engineering departments or those who maintain and operate medical equipment, should be certified. However, the current number of CEs who fall into this latter category is only about 50 and, despite the expected increase to 200 in near future, it is felt that this number is too small to justify the establishment of the certification system for CEs. Therefore, instead, there is hope that an international certification system and clinical engineering certification guidelines can be established.

Because well over 10,000 CETs were working in hospitals in Japan, a CET certification system for was established. In Japan, medical doctors and nurses have had to solve equipment-related problems in the hospital, despite having little, if any, relevant education and training to do so. Because they lack the knowledge to operate this life-support equipment safely, this role is performed by the CET. A small number of CETs also perform maintenance and repair of clinical equipment.

Clinical Engineering in Societies and Committees

To improve the clinical engineering system in Japan, clinical engineering committees have discussed what would constitute the most suitable clinical engineering system for the Japanese hospital. Three Japanese scientific organizations are concerned with clinical engineering issues: (1) the Japan Society of Medical Electronics and Biological Engineering (JSMEBE); (2) the Medical Instrument Society of Japan (MISJ); and (3) the Executive Committee for Dialysis Therapy in Japan (ECDTJ). JSMEBE is the affiliated society of the International Federation for Medical and Biological Engineering (IFMBE) and is involved mainly with basic medical engineering research. MISJ is rather clinically oriented. Each of these three organizations had their own Committee of Clinical Engineering until 1982, when the three combined to form the Joint Committee on Clinical Engineering. They now meet several times a year to discuss the many matters concerning clinical engineering in Japan.

Because their histories and current medical systems are different, each country has its own policy regarding the organizations of paramedical personnel and respective educational systems. In Japan, for example, those who want to work as paramedics in the clinical field must obtain national licenses, which are certified by the Ministry of Health and Welfare. Prior to 1987, the Japanese Government authorized eleven kinds of paramedical occupations: (1) nurse; (2) clinical laboratory technician; (3) clinical radiation technician; (4) physical therapist; (5) occupational therapist; (6) prosthesis technician; (7) dental hygienist; (8) eye therapist; (9) massager; (10) acupuncturist; and (11) bonesetter.

After several studies and meetings, the Joint Committee proposed a structure for the clinical engineering system, which was suitable for Japan. To safely use modern sophisticated equipment, all medical personnel should have a minimum knowledge of electromedical safety and other medical engineering problems. In addition, clinical engineering specialists are needed for this purpose. They are divided into two groups: Clinical engineers and clinical engineering technicians. The CET is equivalent to the BMET in the United States, and the CE is equivalent to the CE in the United States.

Clinical Engineering System Suitable for Japan

In the 1980s, the Joint Committee understood the main purpose of clinical engineering in the United States and in many other countries simply to be keeping medical devices in good condition. They did not see the role of clinical engineering encompassing the operation of medical devices. Therefore, the main responsibilities of clinical engineering in these countries were considered to be preventive maintenance, safety checks, and repair of equipment. The Joint Committee, on the other hand, concluded that clinical engineering in Japan should include all matters concerned with medical engineering equipment; i.e., health care technology management (David and Judd, 1993), from evaluation for purchase of new equipment to the decision to retire old equipment, as well as the operation of some equipment such as hemodialysis machines and heart-lung bypass units. The Joint Committee also considered that clinical engineering should contribute to medical research in hospitals from the engineering point of view.

The Joint Committee proposed a clinical engineering system. CETs must be certified by the Ministry of Health and Welfare. Educational requirements for the CET are at the same level as the clinical laboratory technician and the clinical radiation technologist, but also include a rather basic and broad knowledge of engineering. This engineering knowledge is required because the CET most likely will encounter a wide array of medical device technologies on the job. They also should have enough basic knowledge to

understand new clinical equipment as it is developed and introduced into the health care system. If more advanced knowledge is required for the operation of complicated therapeutic equipment, such as a hemodialysis unit, it is recommended that special clinical engineering technicians or those CETs who were specially trained and certified by an appropriate nonprofit society (in addition to the national certificate) should operate the equipment. Clinical engineers, those who supervise all paramedical technicians directly concerned with clinical equipment, should be certified by a nonprofit society.

The Joint Committee of Clinical Engineering had long discussions with the Ministry of Health and Welfare about the certification of clinical engineers and clinical engineering technicians. At the end of 1986, the Ministry decided to improve the situation in clinical engineering in Japan in order to keep sophisticated medical equipment in a safe and reliable condition and to operate them safely. The Ministry discussed with the Joint Committee the clinical engineering system that was suitable for Japan. The Ministry and the Joint Committee agreed that the system, proposed by the Joint Committee, was the most suitable system for Japan. It drafted a bill for the Clinical Engineering Technician Law, and the bill was passed by the Japanese congress in June 1987. With the bill's passage, the position of clinical engineering technician became the 12th paramedical occupation authorized by Japanese government. Recently, emergency and ambulatory technicians were nationally authorized, as well.

Clinical Engineering Technician Law

The purpose of the Japanese Clinical Engineering Technician law is the qualification of CETs for the improvement of medical services. The definition of CET is a paramedical person who has a license from the Minister of Health and Welfare and operates, maintains, and inspects clinical life-support and control systems under the direction of medical doctors. A clinical life-support and control system substitutes or assists human life functions of respiration, circulation, and metabolism. A person who wants to work as a CET must pass a national clinical engineering technician examination after graduating from a three-year special college for CETs or an equivalent educational system, and must be certified by the Minister of Health and Welfare.

Education

There are many educational paths that prepare one to be eligible for the national CET examination. The most common is a three-year special college that provides the necessary CET education and training. One alternative is the completion of studies at a one-year special CET college after graduation from a two-year college. Other ways to obtain eligibility exist as well. The law prescribes the CET curriculum of the three-year special college, as shown in Table 27-1.

Because clinical engineering technicians are destined to work on a wide range of clinical equipment problems in the hospital, twice as much time is devoted to basic engineering than to basic medicine and clinical medicine combined. The 33 special CET colleges in Japan graduate about 1500 students each year.

Job Responsibilities

The tasks of the CET are as follows:

- Operation, maintenance, and inspection of clinical life-support and control systems
- Ventilators
- Heart lung bypass units
- Hemodialysis units
- Intensive care units
- Hyperbaric chambers
- Therapeutic equipment (e.g., intra-aortic balloon pumps (IABP) and defibrillators)
- Maintenance and inspection of clinical engineering equipment

National CET Certification Examinations

When the national CET examination program first began, technicians who had been working in Japanese hospitals for at least five years were eligible to sit for the exam. This five-years experience criterion was in effect from 1988 to 1993. During that period, about 13,700 technicians applied for this annual examination, and about 10,000 technicians passed. Since 1994, the national CET certification examination is given each year to applicants who have graduated from the special three-year colleges or from four-year special universities for clinical engineering technicians. Since its inception, the national CET examination process has resulted in the certification of about 17,000 CETs.

Table 27-1 Three-year CET curriculum

Subjects	Time (hours)
Cultural subjects	420
Basic medicine	345
Clinical medicine	240
Basic engineering	765
Clinical engineering	900
Others	330
Total	3000

Distribution of Certified Clinical Engineering Technicians

The distribution of nationally certified CETs is quite different from that of other countries. Of the certified CETs currently employed, 11,000 are working mainly in the operation of hemodialysis units (dialysis techs), 700 in extracorporeal circulation (perfusionists), and 600 for intensive care units (monitoring technicians). Others are working in respiratory therapy (respiratory therapists), and still others in the maintenance of medical devices (biomedical equipment technicians). The Joint Committee recommends that all certified CETs should increase their skills such that they are able to do all of the above jobs. However, it is difficult to change the clinical engineering system in Japanese hospitals.

The most urgent problem facing CETs is how best to work within the organizational structure of the hospital. Special paramedical personnel have long been working in many Japanese hospitals because of the need for those with the engineering knowledge necessary for dealing with modern, sophisticated medical equipment. These paramedical personnel—engineers as well as technicians—are attached to various hospital departments. Most Japanese hospitals do not have special departments for clinical engineering. Only 15% of these paramedical personnel belong to clinical engineering departments. The other clinical engineers and technicians work in other areas of the hospital because doctors find it convenient to have their own clinical engineering technicians in their departments. Most of these technicians have passed the examination and hold a license for working as a CET. Today, throughout Japan centralized clinical engineering services by way of a clinical engineering department are the exception. The rule or common practice on the other hand is the decentralization of CE and CET services in disparate department throughout individual hospitals. With such a decentralized model and, consequently, the lack of a critical mass within a centralized department, health care technology management and other higher-level clinical engineering functions become increasing difficult. With the lack of these services, the hospital, in turn, suffers by inefficient acquisition and use of technology, increased costs, and lower quality of patient care. (See Chapter 30.)

Urgent Problems of Clinical Engineering in Japan

The most urgent problem is the need to revamp the curriculum in the three-year special college for clinical engineering technicians. The Ministry of Health and Welfare has prescribed the clinical engineering technician curriculum in all 33 three-year special colleges and the four-year special universities. It is felt that the time allotted is insufficient to adequately teach the students what they need in order to be an effective CET. Therefore, a new systematic method is needed, to give students a broader and more relevant education in engineering, medicine, and clinical engineering.

An educational system for clinical engineers also should be established. The Joint Committee of Clinical Engineering recommended that the education level for clinical engineers should be at least two years of graduate school in clinical engineering. In Japan, a suitable educational system for clinical engineer does not exist. Only a small number of clinical engineers who have enough ability to manage and to supervise clinical engineering technicians are working in hospitals in clinical engineering. Therefore, in order to increase their numbers, it is urgent that an education system for clinical engineers be established. (See Chapters 66 and 68.)

Japan does not have a certification system for clinical engineers. The Joint Committee of Clinical Engineering is discussing the systems that might be most suitable for the certification of clinical engineers, and it looks to the international community for possible models or affiliation. IFMBE has a Clinical Engineering Division (CED). Over the years, the IFMBE CED has held two meetings per year, in which various problems on clinical engineering and aspects of the international certification system for clinical engineers were discussed. Unfortunately, the expected contribution of CED in promoting the establishment of a world certification system for clinical engineer did not materialize. The American College of Clinical Engineering (ACCE) Clinical Engineering Certification Program (see Chapters 130 and 133) is worth studying for its application to addressing the certification needs of clinical engineers in Japan.

CETs in Japan do not have a society. The author recommends that the Joint Committee assist with the organization of a society for them. Most clinical engineers are members of JSMEBE and contribute their expertise through their work on the JSMEBE clinical engineering and education committees.

Unfortunately, the rapid progress of medicine has brought with it many social problems. These include structural change of disease, increasing numbers of elderly people, economical problems, ethical problems, and safety and reliability of medicine (Bronzino et al, 1990; U.S. Congress, 1987). Clinical engineers have the necessary education, training, and experience to solve these social problems. Japan recognizes the valuable contribution that clinical engineers must make in solving the problems relating to the use of the health care technology of today and tomorrow.

Clinical Engineering in Mozambique

Enrico Nunziata

Health Care Technology Management Consulting
Torino, Italy

Momade Sumalgy

Director, Department of Maintenance, Ministry of Health
Mozambique

Clinical engineering in developing countries, particularly in sub-Saharan Africa is different in many aspects from that in developed countries. Often, there is no history of clinical engineering in the health services of developing countries, and external forces (usually bilateral or multilateral donors) often introduce inappropriate maintenance concepts. The major factors affecting the development of clinical engineering in developing countries are the following:

- A lack of a maintenance culture at all levels in the health service
- Extremely scarce resources (financial and material)
- Low productivity and a lack of skilled manpower
- The transfer and use of inappropriate technology

Clinical engineering in Mozambique should cover not only the maintenance of infrastructure and vehicles but also the management of all of its physical assets (also known as health care technology). Physical assets include equipment (medical and general), vehicles, infrastructure, and other installations (e.g., central medical gas supplies). The direct transfer to Mozambique of clinical engineering models developed in western countries and, more recently, in Latin America, is not appropriate, due to technical difficulties and deep cultural differences. This chapter gives a description of a physical-assets management model being developed in Mozambique, along with its strengths and weakness.

Mozambique

Table 28-1 provides some background information on Mozambique. More detailed information is available at the official National Institute of Statistics website: www.ine.gov.mz.

Brief History of the Maintenance System in Mozambique

Prior to independence in 1975, maintenance in the health service had been provided by outside contractors. On the eve of independence, the contractors left, and consequently there was no maintenance being carried out. A centralized national maintenance center was slowly created in the capital city of Maputo, with the support of donors. Staff, from plumbers to X-ray technicians, were introduced and trained to different levels. Maintenance centers were also introduced in the provincial capitals. They were entirely dependent on the National Maintenance Center in Maputo for their supplies—everything from the paper they wrote on to spare parts. The connection between the provincial maintenance centers and the local health service was negligible and sometimes nonexistent.

In 1987, the Government of Mozambique and multilateral donors agreed to implement a Structural Adjustment Plan, and the health service started on a recovery program. At the beginning of the decentralization process in the early 1990s, three specialized maintenance services were opened in the three major hospitals in the country (in the southern, central, and northern regions). More maintenance staff were introduced and trained. Some of the medium-level technicians gained work experience with the help of technical advisors funded by donors. Little formal training was done outside the country, except for occasional short courses provided by medical companies for newly acquired equipment. Centralized planning enabled equipment (i.e., medical

and supporting hospital equipment) to be standardized. Consequently, the same types and models of machine were found across Mozambique's health facilities, and, therefore, spare parts planning and acquisition (or donation) of new equipment were simplified.

As the economy continued opening, the private market developed, and some public institutions, like the state-owned electrical and communication companies, were partially privatized. The search for skilled technical manpower drained the already minimal human resources acquired by the health service, and the most capable technicians left. At the end of 1996, the National Maintenance Center in Maputo was stagnant. Few technicians from the center were traveling the country to perform maintenance on medical equipment. Infrastructure maintenance was nonexistent, and most of the government budget for maintenance was absorbed by the repair of vehicles. The National Maintenance Center was totally disconnected from the rest of the health care system. There was no leadership, no control system, no established priorities, and no recorded measurement of the work performed. A new leadership team took over the Directorate of Administration and Management and the Ministry of Health (MOH) as a whole. The maintenance sector underwent a profound change with the support of external technical assistance grants and the willingness to access donors' or soft-loan funds. This change is still ongoing. The reforms were policy document, strategic planning, information system, and Training.

The Policy Document

Around the end of 1996 and the beginning of 1997, the then National Maintenance Center proposed a policy document to reorganize the maintenance systems in the MOH. The document underwent several discussions in the ministry, and after a consensus was reached the MOH Coordination Council approved the new policy, which was signed in July 1997. The policy document was very simple and brief, outlining the major concepts of management and maintenance of physical assets in the health service. It detailed the most important steps that were necessary to create an efficient and sustainable system

The New Organization and the Strategic Plan

Following the adoption of the new policy, a new organizational structure was introduced. Under the new structure, the old National Maintenance Center became the Department of Maintenance, whose responsibilities changed from intervention to regulation and monitoring. In the provinces, the old maintenance centers were supposed to be transformed into management and operational services within the Provincial Directorate of Health. They were to provide professional advice as well as intervening in physical assets management and maintenance. With these changes, the new system was born, but the system was far from operational. There were many constraints, such as a limited skill base and limited material resources available, especially in the provinces. Therefore, a strategic and operational plan, defining the steps to take in the fields of human, material, and financial resources, was prepared in order to complement the policy document. The strategic plan included, among other issues, the following information:

- The typical structure in term of space, human, and material resources of the maintenance unit for each level of the health service pyramid
- An estimation of the financial resources (recurrent costs) needed for maintaining the physical assets, based on a percentage of the estimated replacement cost
- An estimation of the financial resources (capital cost) needed to improve and develop the maintenance sector in terms of infrastructure, material, and human resources

Table 28-1 Basic statistics for Mozambique

Population (1997 Census)	16,099,246
Surface area	799,380 km
Infant mortality rate (IMR)	145.7/1000
Life expectancy at birth (average for men and women)	42.3
Gross domestic product (GDP) per capita (1998)	236.9 USD
Minimum salary (1998)	20.5 USD

The strategic plan was finalized in late 1998, and implementation started during the first quarter of 1999.

The Information System

No system can be managed without information, especially when the system to be managed is not homogeneous and is distributed over a large area, as in Mozambique. Therefore, one priority was the development of an information system (IS) and the regular collection of data. In late 1997, a nationwide information system was introduced, and data collection on assets and maintenance activities started. The IS did not include any preventive maintenance procedures, but the work order form allowed one to differentiate between preventive maintenance and corrective maintenance. The data collected produced a set of databases containing information on equipment around the country. It allowed the Department of Maintenance to produce an annual Retro-Information Bulletin with analysis of the raw data and to produce tentative comparisons among the different maintenance centers around the country. This first IS contained only indicators regarding medical equipment maintenance (e.g., down time and total number of corrective maintenance hours), but no indicators were available to evaluate the system as a whole.

The Implementation Process

In late 1998, one and a half years after the policy became official, the implementation of the policy lagged behind what was expected. It was felt that in the provinces, the directors of health did not know about the policy and its implementation. Probably, one reason for this was that Provincial Directors usually stayed in place for no more than two or three years. Indeed, by the end of 1998, most of the directors who had approved the policy document in 1997 had left for further education or different careers. It became apparent that the administrative system was the key to the successful implementation of the new policy. It was the administrators who, since the early 1980s, really had been managing the provincial health service. The directors—always young doctors who had just finished university—were taking these appointment as a “must do” before proceeding with his or her specialization. They were not interested in management, but only in clinical work. Therefore, the administrative system was not keen on accepting the new *modus operandi* and was delaying introduction of the changes. Consequently, it was decided that the Department of Maintenance in Maputo needed to monitor and to follow up the policy implementation. This decision was backed up by the Directorate of Administration and Management, who decided to host a National Meeting of the Administration and Management Sub-Sector each year. During these meetings, the development of the administrative and management system (of which the Department of Maintenance is a part) is discussed, and constraints are examined in order to be resolved. These meetings were a great help in boosting the whole policy implementation process.

Monitoring

In order to evaluate the development of a system, it is necessary to measure its changes and to create a monitoring system that is able to detect problems and to allow for adjustments. When the policy document, information system, and strategic plan were prepared, no target, and few indicators, were defined. The only indicators used were those relating to the equipment maintenance and inventory activities. During 1999, the Department of Maintenance performed a study. Its objective was twofold. First, the Department of Maintenance wanted to have a better picture of the cost that would be incurred to expand its services and maintenance activities. Second, it wanted to define a benchmark of indicators that could provide a measurement base for the maintenance sector as a whole. The study, based on known literature, provided a series of possible scenarios for the future of the sector and their related costs. It also defined a benchmark of 10 indicators, taking into account the following factors:

- Productivity (single and multi factors)
- Efficiency
- Administrative management capacity
- Assess life-cycle status
- Qualitative evaluation

It defined a “quality indicator” as a weighted sum of the 10 other benchmark indicators.

Training

The skill level of the technicians was, and still is, low. A system works only if enough of the right human resources are in place, and if their responsibilities and hierarchy are defined and respected. Finally, incentives and stimuli are needed, to retain the personnel. To face these challenges, the Department of Maintenance is preparing a comprehensive proposal for the Ministry of Health that defines the human resource requirements at all

levels, from basic biomedical technicians to postgraduate health technology managers. As the salary for technical staff is extremely low, the Department of Maintenance is proposing that the Ministry should create a special career for technical health care personnel, similar to that which exists for nurses. It would allow for a raise in government salaries, due to the special role provided by technical health care personnel in the civil service.

1999–2000: The Preliminary Results

The results of the process started in 1997 with the signature of the policy document, and then with the definition of the strategic plan and its first two years of implementation can be summarized in Figure 28-1 and Tables 28-2, 28-3, and 28-4.

Figure 28-1 provides a graphical representation of the organizational changes to the system as a whole. The vertical structure of the previous system changed into a horizontal structure and allowed integration of the Provincial Maintenance Services into the Directorate of Health.

Table 28-2, provides the Department of Maintenance, in particular, and decision makers in the Ministry of Health, in general, with a graphical representation of the development of the system. To create this table, the Department of Maintenance collected data on the following criteria:

- Policy application and organization
- Human resources
- Infrastructure and material resources
- Information systems

For each criterion, scores were defined for the level of policy implementation. The maximum score for each criterion was 1.00. Looking at Table 28-3 an improvement of almost 100% between 1999 and 2000 can be observed. The number of good, adequate, and bad cells increased from 4, 4, and 12, to 7, 10, and 22, respectively.

Finally, Table 28-4 reproduces the preliminary results of the evaluation of 5 difference maintenance services in Mozambique, based on the benchmark indicators previously described.

The Future

After the first two years of implementation and evaluations (internal and external), the Department of Maintenance initiated a revision of its strategic plan. The process of revision included the following steps:

- Analysis of the 1999–2000 implementation and preparation of the 2001–2204 Strategic Plan
- Revision and improvement of the information system with the inclusion of the benchmark indicators and the inventory and management of the infrastructure
- Revision of the priority areas of the maintenance sector, aligning them with those of the health service as a whole
- Continuous monitoring of the maintenance sector to evaluate its performance and its integration into the health service as a whole

Some of these activities are already under development, and by the second half of 2001 all the revisions should be finalized and the new plan initiated. One major step will be the final separation of the management and the operational responsibilities of the Department of Maintenance.

Conclusion

The change of a system, especially when it has been in place for more than a decade, is a complex, barrier breaking, multidisciplinary effort. It should include a deep analysis of the entire sector of which it is a part, and not only of the one under consideration. Today, the maintenance sector in Mozambique, three and a half years after the introduction of the policy, is still at the beginning of its changing phase. Indeed, even if some major results were achieved, the overall objective of efficient and cost-effective physical asset management is still far away. The difficulties in reaching these objectives are multifarious and different from those encountered when setting up a maintenance service in a hospital in a western environment. In the process, the management core of the Department of Maintenance learned several lessons:

- Culture and social realities are major factors to take into account when planning countrywide physical asset management within the public sector
- Multidisciplinary aspects, such as the administration and logistic sectors, upon which most of the maintenance activities depend, also must be considered
- Donors’ and community interests and priorities, which are not necessarily the same as those of the Ministry of Health, must be evaluated and accounted for
- Priorities and target-setting must be addressed as early as possible and must correspond to those of the health service as a whole. It is important to maintain a comprehensive mix of activities and not to skew the interventions in one area to the detriment of another (e.g., the primary health care level versus the tertiary health care level)
- Monitoring and continuous evaluation activities must be in place from the very beginning, so that situations requiring immediate intervention can be identified and acted upon.

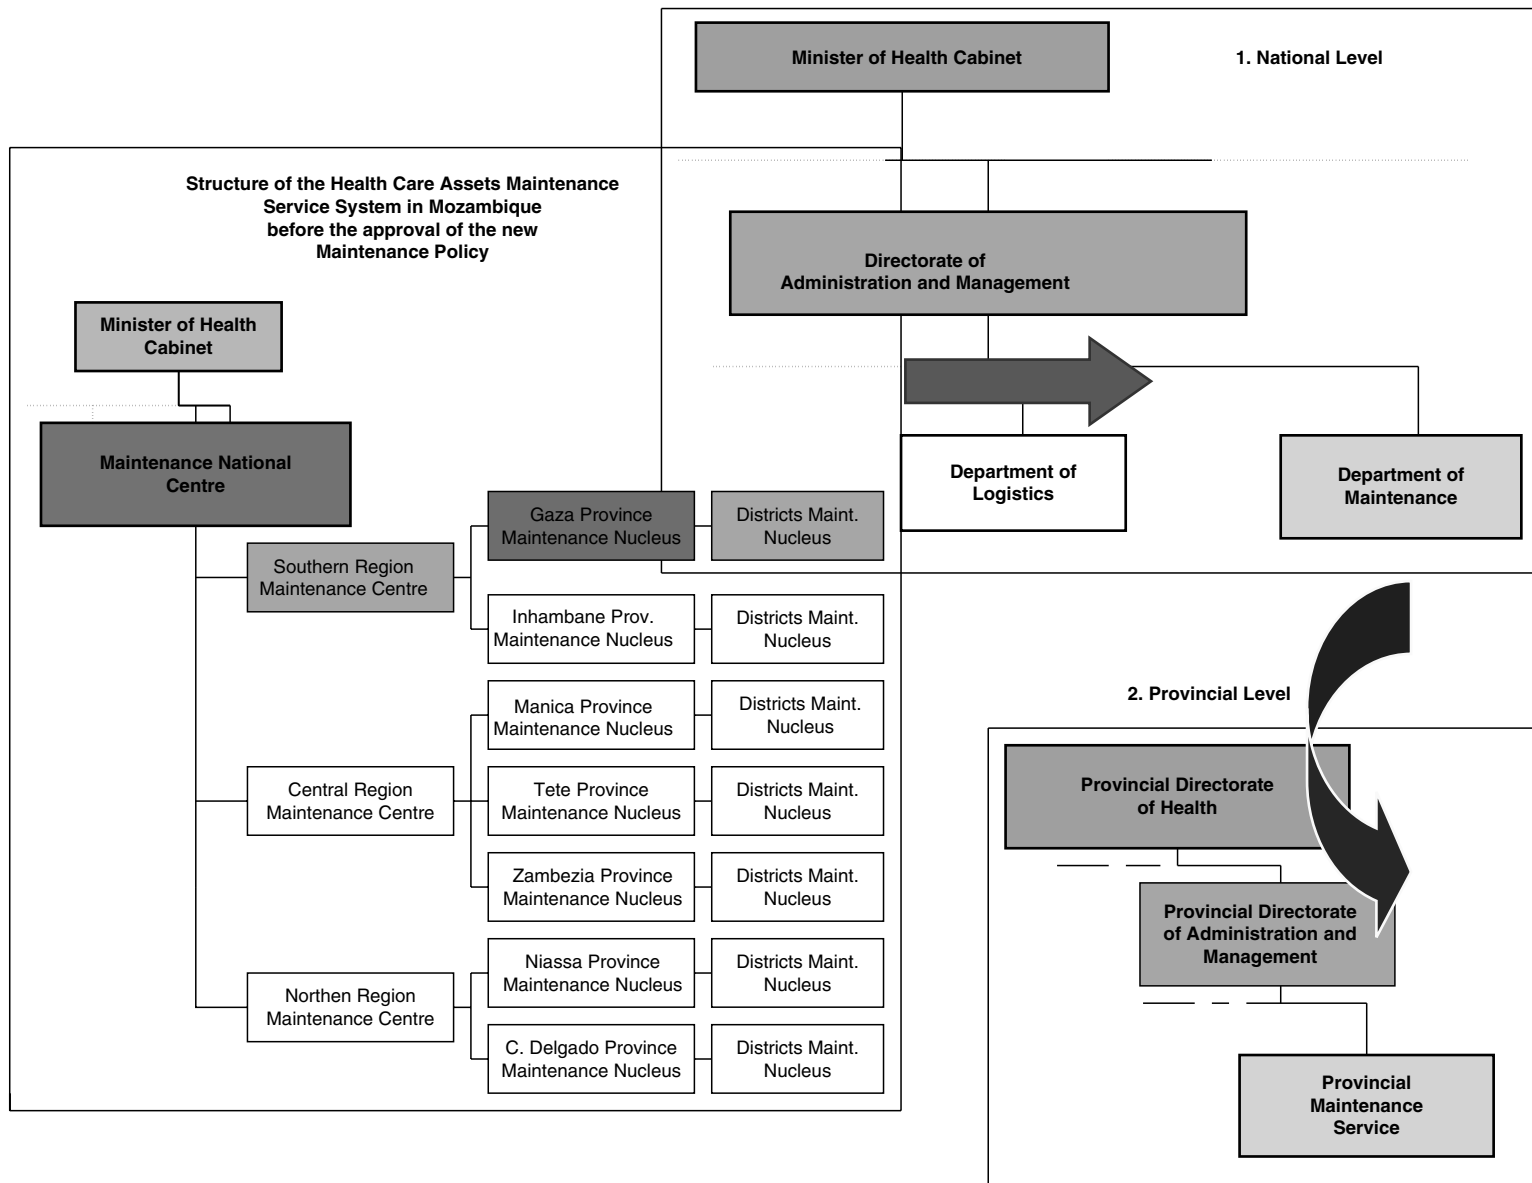

Figure 28-1 The changing from a vertical organizational structure to a horizontal one shows the situation with respect to the inventory process at the end of 1999. The assets inventoried were only medical equipment and hospital supporting equipment such as washing machines or power generators. Only in one province did the inventory include furniture (hospital and general).

Table 28-2 Data of the inventory of medical and general hospital equipment in Mozambique

Clinical Engineering in the Middle East

Hashem O. Al-Fadel

Managing Director, ISNAD Medical Systems, Amman, Jordan

With the existence and influx of many types of sophisticated medical equipment, the management of technology is considered one of the important factors in maintaining a high standard of health care (see Chapter 30). Clinical engineering departments monitor, inspect, and ensure that medical equipment is appropriately functioning and properly acquired for its intended purposes. Management of technology is the primary role of any clinical engineering department in a hospital. Such management begins before the time of purchase and lasts through the life of the equipment, and it includes the disposal process.

Maintenance of medical equipment is one of the main functions that attract most of the attention by users and administrators in any hospital (see Chapter 37). This paper reviews and describes the major problems and concerns facing clinical engineering departments in general and in developing countries in particular (Al-Fadel, 1995). In addition, some solutions to existing problems are suggested, and a perspective on the future is discussed.

Problems and Concerns

Some of the common problems or concerns of clinical engineering departments in the Middle East include the following:

- Long lead-times are required, to obtain needed spare parts. Although most departments try to stock some recommended parts, often the parts needed cannot be found in stock. To obtain a particular part, it may take from three months to a year, as sometimes it is not even in the vendor's stock or in the manufacturer's warehouse.
- Sometimes service manuals are not provided or are not even adequate, thus resulting in longer times to repair.
- Adequate support from some vendors, or even from manufacturers, is often not provided. For example, a vendor might not be prompt in solving the problem. Some local vendors might not even employ qualified service personnel to solve the problems.
- Lack of full awareness of some clinical staff about the roles of clinical engineering departments could result in lack of proper communication between users and the clinical engineering staff.
- Some types of equipment might have intermittent problems that could be caused by age, design problems, or the environment. This problem may occur in any health care institution and is addressed by technical departments throughout the world.
- Difficulty in finding well-qualified technicians or engineers often occurs.
- Difficulty in maintaining some equipment by in-house personnel because of the lack of standardization often occurs. Having many one-of-kind devices, each of which requires that the staff obtain special training for servicing, places an onerous burden on the training resources that are available to the department.
- Sometimes there is a lack of competent in-house training programs offered for users and clinical staff.
- Not enough trained local staff are necessarily available to meet hospital needs.
- The process of training staff is long.

Discussion

These problems are common not only in the Middle East, but in hospitals worldwide—even in many hospitals in the industrialized countries (see Chapter 15). Cooperation among hospitals, and proper selection of equipment from cooperative vendors and manufacturers are crucial for long-term equipment support. Other factors, such as increasing clinical engineering awareness by clinical engineering departments presenting seminars to the clinical staff, training programs for local clinical engineering graduates, and emphasis on standardization in the purchasing process, will contribute positively toward reducing these problems. These efforts are made in few clinical departments but are not consistent from one hospital to another.

In Saudi Arabia in 1990, the Clinical Engineering Club was founded at the King Faisal Specialist Hospital and Research Center in Riyadh. The club has started the process of cooperation among hospitals in terms of technical consultations, seminar presentations, and expertise exchange. This process can strengthen the cooperation among the technical departments to a certain extent and can result in mutual benefit for all hospitals. Similarly, the Egyptian Clinical Engineering Society, when it was active in late 1989, has contributed some assistance to this field. Exchange of information at the international level benefits all parties. In 1991, the King Faisal Specialist Hospital hosted the week-long International Conference on Health Technology Management, which featured the leading clinical engineers and technology managers from around the world. Several clinical engineers from The Kingdom of Saudi Arabia were among two dozen participants at the 1st Advanced Clinical Engineering Workshop, held in Washington, DC, in 1991 (see Chapter 70). Other examples of international cooperation and information exchange can be found in non-governmental programs to improve health systems. For example, Project HOPE provided financial and technical assistance in Egypt between 1979 and 1986 (Weed and Gellert, 1995).

The problem of acquiring spare parts in a prompt manner needs a great deal of attention and research by all departments in order to find the optimum solutions. This may include setting guidelines on agreements of sharing services, experience, and, possibly, spare parts among hospitals. Another possibility is for hospitals to have comprehensive service agreements with experienced major original equipment manufacturers (OEMs) for optimum service. These subjects could be open for discussion toward any suggested practical solution.

One cannot deny the fact that local vendors will not be able to stock spare parts for equipment other than that covered by service contracts. In the meantime, the suggested or recommended spare parts to be purchased by customers are often exaggerated. Accordingly, neither vendors nor customers can maintain sufficient stocks of spare parts. This situation can be nearly corrected by rationalizing the lists of recommended spare parts and by offering them at lower profit margins.

Future Outlook

Clinical engineering departments should continue striving to keep up with the rapid future technology demands and to increase the awareness of hospital administrations to support their continuous staff development programs. More meticulous planning for stocking a

reasonable number of spare parts, especially for vital equipment, in order to minimize equipment down time, should be implemented. Careful selection of equipment for purchase with an emphasis on after sale service is a necessity, to avoid withdrawal or lack of service support. Relationships with clinical engineering departments in neighboring local and regional hospitals should be strengthened by way of activities such as clubs, seminars, and workshops, to promote cooperation in technical support.

Conclusion

Managing health care technology has become an important aspect of the operation and maintenance of hospitals. Local experience by clinical engineering departments in hospitals indicates that problems encountered do not differ widely from those experienced by similar departments worldwide. Maintaining stocks of spare parts, having the correct service documents, staff development programs, and recruiting qualified technicians are the main concerns of the clinical engineering departments in hospitals. Finally, the high-technology equipment always should be maintained by major OEMs or sole agents, to minimize down time and to increase availability and productivity of technology.

Mutual cooperation among regional hospitals is one way to overcome most of the major problems encountered. Hospital administration support is needed more than ever, to aid the management of health care technology. The successful transfer of high technology demands recognition and support for CE training and practice from health care policy makers and administrators (Weed, 1989). As the cost of this technology continues to increase and the technology's complexity grows, the need for effective management will grow commensurately. To avoid being overwhelmed by the advances of technology, a systematic and innovative approach is needed.

Section III

Health Technology Management

Thomas M. Judd

Director, Quality Assessment, Improvement and Reporting,
Kaiser Permanente Georgia Region
Atlanta, GA

Health care systems everywhere face the *STEEP* test of being Safe, Timely, Effective, Efficient, Equitable, and Patient-centered. Meeting these current and perceived future challenges to improve health care content and delivery are often associated with using increasingly sophisticated technologies for diagnosis and treatment. Health care technology management activities offer a range of solutions to address these requirements and to improve quality while reducing cost. These activities include, but are not limited to, setting technology priorities based on the disease burden of the population served, allocating resources (physical, financial, and human) matched to these health needs, and managing these resources through their full cycle of potential use. This section will review the full spectrum of those activities.

The 2001 U.S. Institute of Medicine (IOM) Report regarding 21st century health care in the United States suggests *highest quality care* would be achieved when:

- All preventive, acute, and chronic care services are delivered accurately and correctly.
- All indicated services are delivered at the right time.
- Services not helpful to the patient or reasonably cost-effective are avoided.
- Safety hazards and errors that harm patients and employees are avoided.
- The patient's unique needs and preferences are respected.

The definition of *health technology* used by the World Health Organization (WHO) includes drugs; devices; medical and surgical procedures; the knowledge associated with these in the prevention, diagnosis, and treatment of disease as well as in rehabilitation; and the organizational and supportive systems within which care is provided. This section of the Handbook does not include focus on management of drugs, technology users, or evidence-based clinical procedures. However, it does include management of other health technology *assets*, such as medical devices and supplies; physical infrastructure, such as health buildings and associated services and utilities; and logistics support and information systems. These latter items are important technology components in ensuring quality and cost-effective outcomes for patients.

Health technology management (HTM) is defined as a systematic process in which qualified health care professionals, typically clinical engineers (with their unique ability to visualize a wide range of systems issues and to determine important linkages and solutions), in partnership with other health care leaders, plan for and manage health technology assets to achieve the highest quality care at the best cost. HTM activities in classical terms begin with strategic planning as well as technology assessment and facilities planning, proceed with technology procurement, and conclude with service or maintenance management.

Nearly 20 esteemed colleagues have made major contributions to this section, describing the impact of a wide range of HTM activities, as conducted in both developed and

developing countries. They and others have contributed to a collection of case studies that WHO analyzed in 1998,¹ demonstrating the quantitative evidence of HTM impacts on the provision of appropriate *STEEP* and *highest quality care*, which are noted below.

Medical Devices	Cost (or Time) Savings
<ul style="list-style-type: none">• Maintenance	20-30%
<ul style="list-style-type: none">• Reduced investment through planning	10-20%
<ul style="list-style-type: none">• Reduced development time for acquisition specifications	(2-4 weeks)
<ul style="list-style-type: none">• Appropriate technology introduction	10-90%
<ul style="list-style-type: none">• User training, reducing maintenance	10%
Health Facilities	
<ul style="list-style-type: none">• Reduced investment through planning	10-20%
<ul style="list-style-type: none">• Reduced time for planning	30%
<ul style="list-style-type: none">• Utilization	
<ul style="list-style-type: none">• Ambulatory care	20%
<ul style="list-style-type: none">• Inpatient care	20%
<ul style="list-style-type: none">• Diagnoses and treatment	50%
Health Delivery System Processes	
<ul style="list-style-type: none">• Chronic disease treatment	
<ul style="list-style-type: none">• Appropriate use of technology	20%
<ul style="list-style-type: none">• Supplies and logistics process redesign	20%

Because HTM activities typically consume 20% or more of all health care capital and operational investments, using the strategies outlined in this section is a must for any health care delivery system in the 21st century.

Introduction to Medical Technology Management Practices

Yadin David

Director, Center for TeleHealth and Biomedical Engineering Department, Texas Children's Hospital
Houston, TX

Thomas M. Judd

Director, Quality Assessment, Improvement and Reporting, Kaiser Permanente Georgia Region, Atlanta, GA

Raymond P. Zambuto

CEO Technology in Medicine, Inc.
Holliston, MA

The quest of every society is to continuously improve the quality of its members' lives, through promotion of health, prevention of disease, and access to an efficient health care delivery system. Many different methods and strategies for pursuing efficient delivery systems have been tried, and others will be experimented with in the future, but it is evident that we have not yet found the optimal approach. Health care ranges from the fight against diseases to the maintenance of physical and mental functioning, and its delivery largely depends upon technology, especially medical technology. Therefore, medical technology management is one of the most important segments of the health care system, and it is the segment that carries the best potential for clinical engineers (CEs) to demonstrate their unique expertise and leadership excellence.

Medical technology contributes to the advancement of health care in many ways. It contributes to screening of abnormalities and their risks. It contributes to the diagnosis of clinical signs that identify the nature or the cause or the extent of the pathology. It contributes to treatment in the restoration, improvement, and replacement of bodily function as well as preventing further deterioration or pain sensation. It contributes to rehabilitation by restoring, replacing, improving, or maintaining physical or mental function impairment. Technology is expected to reduce the risk of a disease, shorten illness duration, improve the quality and accuracy of care, increase access to care, and replace or limit the decay of a person's functions so and return that person to a state of quality life. In addition, technology is expected to contain cost, to enhance healthy behavior, and to reduce intervention risks. In summary, acquisition of medical technology is accomplished primarily for the following five reasons:

1. To improve diagnostic, therapeutic, or rehabilitation efficiency.
2. To increase the health system's cost-effectiveness or reimbursement.
3. To reduce risk exposure and eliminate errors.
4. To attract high-quality professionals.
5. To expand the service area or to better serve the beneficiary base.

Health care delivery systems around the world are going through major transformations. While knowledge is continuously being created and disseminated at an accelerating rate, the allocation of resources for implementation of preferred solutions is lagging behind, creating a gap that could overwhelm the system if left unchecked. This chapter addresses technology management practices that close this gap by achieving an efficient and effective methodology for the assessment and deployment of medical technology.

Technologies in general, and medical technology in particular play a significant role in the health care transformation. To ensure that technology is safe and effective, there is a need to understand adequately the potential of technology and the importance of its associated management methodology and tools. Without such management methodology and tools, technology function and patient outcomes will be impaired. Forward-looking managers recognize that properly constructed medical technology management methodologies and tools provide objectives and guideline protocols for efficient practice and decision making processes in the following stages in the technology life cycle:

- Strategic technology planning
- Technology assessment
- Technology acquisition and implementation
- Technology risk management and quality improvement
- Technology utilization and servicing
- Technology value or cost/benefit ratio analysis

The management of assessment and deployment of safe and effective medical technology lags behind both the knowledge and practice patterns of management in general. In the

highly complex environment of the health care delivery system, the challenge to invest in management methods and practices has diminished such that the consequences of medical technology decisions are inadequately factored into the larger strategy. While this varies from one patient population to another, and from one hospital type to another, these management tools, where they are used, have a direct impact on patient care outcomes, hospital operations, and financial efficiency. Only by applying these tools and methodologies can the system optimize the development of medical technology and the facilities that house it.

There are three types of managers: Those who make things happen, those who watch things happen, and those who wonder what happened. This chapter describes the managerial tools that can facilitate the transformation of a "watcher" into a "maker".

Strategic Medical Technology Planning

The health care delivery system is going through a transition that is driven by four major forces: Budget, structure, technology, and social expectations. The impact of any one or combination of these forces may change from time to time, as does their relative significance, creating a result that is the subject of public debate. It is clear, however, that health care is being subjected to mounting pressure by the needs to (1) identify its goals; (2) select and define priorities; (3) allocate resources more effectively; and (4) achieve system-wide integration.

The health care delivery system presents a complex environment wherein policies, facilities, technologies, drugs, information, and a full range of human interventions interact. It is in this clinical environment that patients in various conditions, skilled staff, contract labor, and a wide variety of technologies converge. The dynamics of this swirling environment, as they relate to medical technology management, include leadership, resources, competencies, risk exposure, regulations, rate of change, and the ability to demonstrate impact on outcomes.

Care providers are faced with the ubiquitous presence of medical technology at the vortex of changing provider and patient roles compounded by system accessibility and integration challenges. Society demands, in addition to user competency, improved quality of care, reduction in error rates, and containment of expenditures. Without a systematic approach, this scenario often leaves hospitals without a clear direction for meeting these expectations. Short-term cost pressures can drive hospital decisions that conflict with the other factors.

One apparent solution that would bring a sense of order and reason to this volatile environment is to seek ways for hospitals to more effectively manage their available technology resources and to do more with less available capital by only selecting "appropriate" technologies that have longer and more reliable life cycles. Proven technologies that fit well into their budgets and operations can be supported and relied upon to provide safe and effective care. Health care delivery organizations have begun to combine strategic technology planning with other technology management activities in programs that effectively integrate decisions about adoption of newer technologies with the hospital's existing technology base—a process that has resulted in better care outcomes at higher efficiencies. Well-integrated medical technology programs will steer hospitals through these transition times by improving performance, eliminating preventable errors, and reducing operational costs.

The Scope of Technology to Be Managed

Technology, as defined by David and Judd (1993), means merely the use of "tools," that is, the involvement of any agent that assists in the performance of a task. In this context, the technology that has been developed for, and deployed in, the health care delivery system ranges from the "smart" facilities within which care is being provided to the products that

are used in and around the provision of health care services. Technology “tools” have been introduced at an increasing rate during the past 100 years and include the use of techniques, instruments, materials, systems, facilities, and information. Of all the factors and resources that will shape the future of the health of humankind, the one that most often stretches the imagination is medical technology. However, medical technology is often blamed for contributing to the escalation of health care costs without receiving recognition for improving access to the system and the quality and efficiency of the system.

The past decade has shown a trend toward increased legislation in support of more regulations in health care. These and other pressures will require technology managers to be familiar with the regulations and to be able to manage a program that demonstrates compliance with these requirements throughout the life cycle of the technology. If you subscribe to the saying, “You cannot manage what you do not measure, and you cannot measure what you do not define,” then the need for the development of a systematic and comprehensive planning process for technology adoption is obvious. In terms of defining the scope of technology to be managed, the health care organization must develop a rationale for adoption. Without this most basic tool, the process becomes increasingly randomized over time until no consistent system of management can survive. One example of a ranking of rationale for technology adoption is the following list:

Clinical Necessity

- Contribute to meeting/exceeding standard of care
- Positively impact care quality or level
- Impact life quality
- Improve intervention’s accuracy, specificity, reliability, and/or safety
- Reduce disease longevity/length of stay

Operational Support

- More effective care/protocol/decision making
- Impact operational efficiency and effectiveness
- Impact development or current service offering
- Impact liability exposure, contribute to reduction in errors
- Increase compliance with regulations
- Reduce dependence on user skill level
- Impact supporting departments
- Increase utilization rate and reduce maintenance load

Market Preference

- Impact access to care
- Increase customers’ convenience and/or satisfaction
- Impact organization or service image
- Improve return on investment (ROI) or revenue stream
- Lower the cost of adoption and ownership
- Impact market share

Strategic Planning Process

The strategic planning process is the road map for the introduction and development of technology and services, and their related policies into the core business of the hospital to maximize the value outputs of the program. The outputs of this process are measured as changes in cost, quality, performance efficiency, or quality of life. The road map is an important guideline because it identifies a common vision for timely response to fundamental needs. The following key components must be present in the plan to ensure the optimal allocation of funds needed:

- Regional planning, coordination, and technology assessment
- Strategic technology planning and priority setting
- Budget development and approval processes
- Technology management and service planning
- Technology acquisition
- Technology audit and risk management

A technology strategic plan is derived from, and supports, well defined clinical objectives. The ability to contribute to this process and the development of these components and their interaction with budgeting processes require a unique set of skills and technical management expertise that is consistent with the characteristics of a mature clinical engineering professional. This expertise facilitates the integration of clinical objectives with management and technical threads that permeate the organization. This aspect of the planning process must include the following elements:

- Creation of a plan to support the facility’s vision and communicate its process to staff
- Periodic review of the alignment between the vision and strategy
- Identification of areas/topics where changes are needed
- Determination of priorities and creation of a plan to meet the objectives
- Inclusion in the plan of the details of specific expectations from information technology, medical technology, and building spaces—transforming experts’ knowledge into service strategy
- Delineation of clinical goals for road map planning, interaction with operations and capital budgeting processes, acquisition and deployment timing, equipment asset management, and monitoring and evaluation

In order for the planning process to maximize the value it adds, it must include standard elements of analysis and must be somewhat predictive in several areas where trends may change over the course of implementation of the plan. The planning process must include the following elements:

- Assess changing clinical goals. The clinical goals are updated annually. For a given year, key hospital participants, through the strategic planning process, determine the clinical services that the hospital should be offering in its referral area. These must be projected with accuracy at the outset.
- Take into account health care trends, demographic and market-share data, and space and facilities plans.
- Analyze the facility’s strengths and weaknesses, goals and objectives, and opportunities and threats.
- Conduct an audit of the existing technology base, including its condition, life expectancy, and utilization rate.
- Audit and project the costs of health care providers using the existing technology, considering turnover of personnel as well as technology.
- Integrate assessment and prioritization of new and emerging technologies.
- Ensure strong compliance with and support of anticipated technological and utilization standards.
- Review technological trends and their operations impact.

If all of these areas are considered, the outcome of this process will be the following:

- A coherent plan that supports the objectives outlined in the organization’s vision for the coming year
- A predictable level of technology that is capable of meeting requirements for a standard level of operation in the referral area
- Offerings of better and more efficacious and consistent health care services
- Effective use of limited resources and provision for growth of the organization’s intellectual property
- A strategic technology plan that helps technology managers to match available technical abilities (both existing and new) with clinical requirements and financial capability
- A definition for the level of service expected
- Priorities in budgeting for technological adoption and acquisitions

To accomplish this goal, clinical engineers and technology managers must understand why their institutions’ values and mission are as they are; must pursue knowledge and collect information that supports their institutions’ strategic plans; and must be able to translate their operations according to the strategic planning process utilizing the often limited resources allocated to them. Although a technology manager might not be assigned to develop an institution’s overall strategic plan, he or she must understand and be ready to offer logical and informative input to the hospital management. The clinical engineer will be prepared to provide this input in the following ways:

- By committing to a professional involvement with, and understanding of, all the hospital services
- By understanding technology assessment methodology and equipment life cycle functions
- By determining the ways in which the hospital’s technological deployment is best evaluated
- By articulating justifications and provisions for adoption of new technologies or enhancement of existing ones
- By assisting in providing a review of emerging technological innovations and in determining the impact that they can have on the hospital. (A good rapport with the research and development industry facilitates this.)
- By visiting the sites of technology development—research or manufacturing—as well as the exhibit areas at major scientific and medical meetings, because tomorrow’s clinical devices are in the research laboratories today
- By being familiar with the institution and its equipment users’ ability to assimilate new technology

The past decade has seen a trend toward increased customer expectations, legislation, and regulation in health care. These developments and financial pressures require that additional or replacement medical technology be well anticipated and justified. Proper planning will provide the rationale for sound technology adoption. Today’s marketplace demands cost effectiveness, competitiveness, and flexibility from every hospital if it is to survive and grow. Such demands require that the effective clinical engineer be able to articulate the differences among factors such as clinical necessity, code compliance, management support, market preference, and arbitrary decision.

Technology Assessment

As medical technology continues to evolve, so does its impact on patient outcomes, hospital operations, and financial resources. The ability to manage this continual evolution and its subsequent implications has become a major challenge in all health care organizations. To be successful, it must be an integral part of hospital operations that address the needs of the patient, and it must smoothly mesh people and technology. The manager who commands knowledge about the organization’s culture, the equipment users’ needs, the existing environment within which equipment will be applied, equipment engineering, and emerging technological capabilities will be successful at implementing and managing technological changes.

In the technology assessment phase, the clinical engineering professional needs to wear two hats in order to lead the team and to contribute to the decision making process. The team should incorporate representatives of equipment users, equipment maintainers, physicians, purchasing or reimbursement managers, administration, and other members from the institution, as applicable.

Technology Audit

With a coherent clinical strategic plan in place, the hospital can conduct a credible audit. Each major clinical service or product line must be analyzed to determine how

well the existing technology base supports it and supports the conditions of that technology. A Medical Technology Advisory Committee (MTAC), consisting of hospital management, physicians from major specialties, nurses, program managers, and clinical engineers should be appointed to conduct this analysis. The key steps that should be taken during the audit are as follows:

1. Develop a hospital-wide complete inventory (i.e., quantity and quality of equipment included), and compare the existing technology base against known and evolving standard-of-care information, patient-outcome data, and known equipment problems
2. Collect and review information on technology utilization and assess appropriate Use, opportunities for improvement, and reduction of risk level
3. Review technology users' (physicians, nurses, technologists, and support staff) educational needs as they relate to the application and servicing of medical equipment
4. Determine appropriate credentialing of users for competence in the application of new technologies, assess needs, determine whether requirements are being met, and assess risks involved (credentialing committees will be the primary group to match clinician skills with evolving clinical treatment procedures or protocols)
5. Keep current with published clinical protocols and practice guidelines using available health care standards directories
6. Utilize clinical outcomes data for quality assurance and risk management program feedback

The audit will allow the gathering of information about the existing technology base and will enhance the capability of the MTAC to assess the need for new and emerging technologies as well as the impact of these technologies on their major clinical services. In this assessment, the following issues should be considered:

- Needs
- Value of the technology
- Technical validity
- Ability to assimilate the technology
- Ability to integrate with existing technological platforms
- Medical staff satisfaction
- Impact on staffing and delivery of care
- Impact on facilities
- Impact on standards of care and quality
- Economic considerations (e.g., reimbursement, life cycle costs)

The committee will then set priorities for equipment replacement and implementation of new and emerging technologies, which, over a period of several years, will guide the acquisitions that provide the desired service developments or enhancements. Priorities will be set based on need, risk, cost (acquisition, operational, and maintenance), utilization, and fit with the clinical strategic plan.

Budget Strategies

All of the information collected above will bear on the developing of budget strategies. Strategic technology planning requires a 3- to 5-year long-range capital spending plan. The MTAC, as appropriate, will provide key information regarding capital budget requests and make recommendations to the capital budget committee each year. There is a three-fold purpose for the capital budgeting process:

1. To develop procedures to solicit and review technology requests
2. To coordinate capital expenditures with available resources
3. To determine optimal financing methods for acquisition

The MTAC should review the final capital budget listing in order to recommend when the items should be purchased during the next year and, if possible, to determine if there should be centralized, coordinated acquisition processes planned for similar items from different departments.

Long-term capital equipment budgets are derived from the analysis of replacement life cycles, organization financial conditions, annual operations support costs (including service, upgrades, and repairs) and true needs justification coupled with a 3-year budget cycle. Each item of equipment listed on the budget is highlighted as either a replacement or a new requirement for an existing or new program. The replacement life cycle is modified from standard tables by factors such as average duty cycles and utilization and escalating repair and service history. Economic justifications for clinical services revolve around a "make or buy" decision—whether the service should be performed by the clinical services in-house or should just be purchased from the commercial market. The needs justification usually centers on the capabilities of the clinical staff.

Prerequisites for Medical Technology Assessment

Medical technology has a major strategic factor in positioning the hospital and its perception in the competitive environment of health care providers. Numerous dazzling new biomedical devices and systems are continuously being introduced. They are being introduced at a time when the pressure on hospitals to contain expenditures is mounting. Therefore, forecasting the deployment of medical technology and the capacity to continuously evaluate its impact on the hospital require that the hospital be willing to make the commitment and to provide the support such a program. An in-house "champion" is needed in order to provide the leadership that continuously and objectively plans. This figure might use additional in-house or independent expertise as needed. To focus the function of this program in large, academically affiliated, and government hospitals, the position of a chief technology officer (CTO) is becoming justifiable. While executives have traditionally relied on members of their staffs to produce objective analyses of the hospital's technological needs, they nevertheless are too often sub-

jected to the biases of various interest groups, including marketing and vendor appeals. More than one executive has made a purchasing decision for biomedical technology only to discover later that some needed or expected features were not included with the installation or that those features were not yet approved for delivery. These features have come to be known as "futureware" or "vaporware". Or, alternatively, it may be discovered that the installation has not been adequately planned, ending therefore as a disturbing, unscheduled, expensive and long undertaking.

Most hospitals that will be providers of quality care will be conducting technology assessment activities in order to be able to project needs for new assets and to efficiently manage existing assets within the limits of the available resources. In order to be effective, an interdisciplinary approach and a cooperative attitude are required because the task is complex. The ability to integrate information from disciplines such as clinical, technical, financial, administrative, and facilities in a timely and objective manner is critical to the success of the assessment.

Medical technology includes medical and surgical procedures, drugs, equipment and facilities, and the organizational and supportive systems within which care is provided. This definition focuses on equipment, systems, facilities, and procedures (but not drugs). There are considered to be two tiers of investigation in medical technology assessment, given that it is the evaluation of the effectiveness of equipment, systems, and procedures in treating or preventing disease or injury:

1. Primary: Clinical safety and effectiveness in terms of physical indicators of patient care outcome
2. Secondary: Synthesizing the results of clinical impact to project financial outcome and reimbursement decisions for payers.

This chapter also emphasizes medical equipment management as an essential element of medical technology management, including the notion of the skills to forecast medical equipment changes and the impact of those changes on the hospital market position. While most consideration is usually given to capital asset management (see Chapter 35) when it comes to medical equipment, one should not exclude the accessories, supplies, and disposables from the medical equipment management program. Another often-overlooked factor in medical equipment management is the impact of the maturity of the technology on education and training as well as on servicing. Equipment that is highly innovative, in development or in clinical trials, will have a far different learning curve for users as well as maintainers than equipment based on more mature technologies.

Technology Assessment Program

Increasingly more hospitals are faced with capital or equipment requests that are much larger than the capital budget. The most difficult decision, then, is the one that matches clinical needs with financial capability. In that process, the following questions are often asked: How can a hospital avoid costly technology mistakes? How can a hospital wisely target capital dollars for technology? How can a hospital avoid medical staff conflicts as they relate to technology? How can a hospital control equipment-related risks? How can a hospital maximize the useful life of the equipment or systems while minimizing the cost of ownership?

As mentioned earlier, technology assessment is a function of technology planning that begins with the assessment of the hospital's existing technology base. Technology assessment is, rather than an equipment comparison, a major, new function of a clinical engineering department. It is important that clinical engineers be well prepared for the challenge. They must have a full understanding of the missions of their particular hospitals, a familiarity with the health care delivery system, and the cooperation of the hospital administration and the medical staff. To maximize their effectiveness, clinical engineers need access to database services and libraries; the ability to visit scientific and clinical exhibits; the capability to establish an industrial network; and a relationship with peers throughout the country.

The need for clinical engineering involvement in such a program is evident when one considers the problems typically encountered:

- Recently purchased equipment, or its functions, is underused
- Users experience problems with equipment.
- Maintenance costs are excessive.
- The facility is unable to comply with standards or guidelines (e.g., JCAHO requirements) for equipment management.
- A high percent of equipment awaits repair
- Training is inefficient because of a shortage of allied health professionals

A deeper look at these symptoms using a proper technology assessment analysis likely would reveal the following:

- The lack of a central clearinghouse to collect, index, and monitor all technology-related information for future planning purposes
- The absence of procedures for identifying emerging technologies for potential acquisition
- The lack of a systematic plan for conducting technology assessment, and thus an inability to maximize the benefits from deployment of available technology
- The inability to benefit from the organization's own previous experience with a particular type of technology
- The random replacement of medical technologies, rather than a systematic plan based on a set of well-developed criteria
- The failure to integrate technology acquisition into the strategic and capital planning of the hospital

The following scenario suggests one way to address these problems and symptoms. To address these issues, efforts to develop a technology assessment plan are initiated with the following objectives:

1. To accumulate information on medical equipment
2. To facilitate systematic planning
3. To create an administrative structure supporting the assessment program and its methodology
4. To monitor the replacement of outdated technology
5. To improve the capital budget process by focusing on long-term needs relative to the acquisition of medical equipment

This program, and specifically the collection of up-to-date, pertinent information, requires the expenditures of certain resources and active participation in a network of colleagues who practice in this field. Membership in organizations and societies that provide such information should be considered, as should subscriptions to computerized databases and printed sources.

The Director of Clinical Engineering (DCE) chairs the MTAC while another CE from the same department serves as the committee's designated technical coordinator for a specific task force. Once the committee accepts a request from an individual user, it identifies other users who might have an interest in that equipment or system, and it authorizes the technical coordinator to assemble a task force consisting of users who the committee has identified. This task force then serves as an ad hoc committee that is responsible for the establishment of performance criteria that will be used during the assessment of the equipment described on a Request for Review (RR) form. During any specific period, there might be multiple task forces, each focusing on a specific equipment protocol.

The task force coordinator cooperates with the material management department in conducting a market survey, in obtaining the specified equipment for evaluation purposes, and in scheduling vendor-provided in-service training. The scheduling of the in-service training for the users can be highly frustrating at times, as the shortage of allied health professionals reduces availability for training while increasing the need for training due to higher staff turnover rate. It is highly recommended, therefore, that this activity be well coordinated with the users' group training coordinator.

After establishment of a task force, the committee's technical coordinator analyzes the evaluation objectives and devises appropriate technical tests, in accordance with recommendations from the taskforce. Only equipment that has successfully passed technical tests will proceed to a clinical trial. During the clinical trials, the clinical coordinator collects and then reports to the task force the summary of experiences gained. The technical coordinator then combines the results from the technical tests and the clinical trials into a summary report and prepares the task force's recommendations for MTAC approval. In these roles, the CE serves as the technical coordinator and as the clinical coordinator bridging the gap between the clinical and the technical needs of the hospital.

The technology assessment process, begins with a department or individual filling out two forms: (1) an RR form (Figure 30-1), and (2) a Capital Asset Request (CAR) form (Figure 30-2). These forms are submitted to the hospital's product standards committee, which determines whether an assessment process is to be initiated, and the priority for its completion. It also determines whether a previously established standard for this equipment already exists.

In the RR form, the originator delineates the rationale for acquiring the medical device. For example, the way the item will improve patient care; generate cost savings, support the quality of service; and provide ease of use, as well as who the primary user will be. In the CAR form, the originator describes the item, estimates its cost, and offers some justification for its purchase. The CAR is then routed to the capital budget office for review. During this process, the optimal financing method for acquisition is determined. If funding is secured, the CAR is routed to the materials management department where, together with the RR, it will be processed.

The rationale for having the RR accompany the CAR is to ensure that pricing information is included as part of the assessment process. The CAR is the device by which the purchasing department sends product requests for bid. Any request for review that is received without a CAR, or any CAR involving medical equipment that is received without a request for review is returned to the originator without action. Both forms are then sent to the clinical engineering department, where a full-time employee designated as a coordinator reviews and prioritizes various requests for the committee to review.

Both forms must be sent to the MTAC if the item requested is not currently used by the hospital or if it does not conform to previously adopted hospital standards. The committee has the authority to recommend either acceptance or rejection of any request, based on a consensus of its members. If the request is approved by the MTAC, then the requested technology or equipment will be evaluated using technical and performance standards. Upon completion of the review, a recommendation is returned to the hospital's product standards committee, which reviews the results of the technology assessment, determines whether the particular product is suitable as a hospital standard, and decides whether it should be purchased. If approved, the request to purchase will be reviewed by the capital budget committee (CBC) to determine whether the required expenditure fits within the available financial resources of the institution, and whether or when it might be feasible to make the purchase. To ensure coordination of the technology assessment program, the chairman of the MTAC also serves as a permanent member of the hospital's CBC. Accordingly, there is a planned integration between technology assessment and budget decisions.

As a footnote to this example, it is important that those involved in the process understand fully the way that standards are developed, the way they are used and modified, and, most significantly, the effect of these activities on the entire spectrum of health-related matters. Some standards address, for example, protection of the power distribution system in the health care facility; protection of individuals from radiation sources, such as lasers and X-rays; and protection of the environment from hazardous substances (see Chapter 117). The practicing professional should fully appreciate the intent of standards in general and should participate in their development and use.

Technology Assessment and Clinical Engineering

Clinical engineering departments are at the threshold of a revolution toward the comprehensive management of all health care technology. Increasing pressures for greater

attention to the quality, fiscal containment, and risk mitigation and error reduction should be matched with skillful and competent management focusing on the characteristics of health care technology. A well-organized program will have a significant impact on the hospital's bottom line, which is a highly desirable outcome in today's financial climate. Hospitals and vendors that operate with organized asset management programs are already benefiting from the involvement of clinical engineering professionals. The role of clinical engineers is threaded throughout the program as it relates to medical equipment and systems. Clinical engineers contribute to, and participate in, every phase of the equipment life cycle, from the capital budget planning, the equipment evaluation, and the performance validation, to the acceptance testing, user training, inventory control, repair and maintenance services, and incident investigation. Their involvement improves the planning for the new (and the management of the existing) equipment inventory, thus impacting integration, quality, finance, and risk.

Device Evaluation

One of the best methods of ensuring that the contribution a technology makes is valuable to the hospital is to analyze carefully each medical device in preparation for its assimilation into the hospital operations. This process of equipment evaluation provides information that can be used to screen unacceptable performance, by either the vendor or the equipment, before it becomes a problem for the hospital (see Chapter 33).

The evaluation process consists of technical, clinical, financial, and operational aspects. These aspects were evaluated earlier, as described in the MTAC function; however, the emphasis here is on the clinical engineer's responsibility. It is assumed that in order to fulfill these duties, the CE is familiar with the emerging and evolving technologies and can translate the clinical needs of the users into an effective and comprehensive bid specification document. The document should be clear, facilitating a competitive bidding environment and comparison of vendors and their wares. This document sets the whole equipment evaluation and selection into motion. Validation criteria for key elements, such as system configuration, extent of facility preparation and operation disturbance, performance requirements, users and maintainers training, warranty, documentation, delivery schedule, and implementation plan, should be spelled out. Cost of service support and price for future upgrades need to be locked.

After the vendor has responded to the informal request or the request for proposal (RFP) information, the clinical engineering department will be responsible for evaluating the technical responses, while the materials management department evaluates the financial responses.

In translating clinical needs into a specification list, key features or "must have" attributes of the desired device are identified. In practice, clinical engineering and materials management develop a "must have" list and an "extras" list. The "extras" list contains features that could tip the decision in favor of one vendor, all other factors being equal. These specification lists are sent to the vendor and are effective in a self-elimination process that results in a time savings for the hospital.

Once the "must have" attributes have been satisfied, the remaining "candidate" devices are evaluated technically and the "extras" are considered. This is accomplished by assigning a weighing factor, e.g., 0-5, to denote the relative importance of each of the desired attributes. The relative ability of each device to meet the defined requirements is then rated. Consider the following examples of attributes:

- Accuracy and repeatability
- Ease of use
- Reliability
- Expected user's skill level
- Serviceability and warranty
- Performance
- Compatibility and interchangeability
- Ability to be upgraded
- Safety
- Cost

Each of these attributes is important, but some are more important than others. In assigning the weighing factors, the CE must take into account the relative importance of each of these attributes. He or she should create a bidding environment that will enable a direct comparison of vendors. Therefore, the RFP should provide details of delivery training and installation, a detailed description of the "must haves" and the "extras," and the cost of service and upgrades, as well as identifying recourse for vendor deficiencies.

The performance of the acceptance testing accomplishes the following:

- Verifies by incoming inspection that each medical device received is capable of performing its designed function
- Obtains baseline measures that can be used later to resolve specified problems
- Assures compliance with the equipment management program, the relevant factors of which include:
 - Verification that the chosen vendor has delivered a complete system with all of the accessories and other needed supplies
 - Documentation of full compliance with terms that were prescribed in the Conditions of Sale and agreed upon when the bid was awarded
 - Initiation of an asset control record by the clinical engineering department

This last item is the point where the equipment enters into the equipment maintenance program, the warranty period is initiated (if applicable), and testing criteria are documented.

The review of each of the vendors' responses, the performance of comparative tests and value analysis, and the performance of acceptance testing are the steps that will reduce procurement costs and problems. They will prevent problems such as dissatisfaction, cost overrun, postimplementation surprises, unplanned service costs, slow resolution or delayed response, prolonged startup, performance gaps, overcharges, and unauthorized promises.

Figure 30-1 Request for Review (RR) form.

Existing inventory utilization should be monitored periodically. The utilization level can be measured and compared with the budgeted level. The utilization rate of existing inventory is a good indicator in justifying additional capital requests.

Risk Reduction

Significant progress in controlling risk has been achieved with the early implementation of an equipment management program. With the development of the dynamic equipment risk factors and associated failure analysis techniques, proactive techniques to contain risk can now be implemented (see Chapter 56). These techniques should be used for assessing new equipment as well as for the management of existing inventory. Error avoidance

and lessons learned from analysis of near-miss events are useful tools for further reduction of potential risk (see Chapter 55).

An organization may have a variety of objectives, such as profit, growth, and the performance of a public service. However, a fundamental management commitment to minimizing the adverse effect of accidental loss to an organization is the founding principle of a risk management program. Risk management is the process of making and carrying out decisions that will minimize adverse incidents. Such a program requires development of criteria, identification of problems, and action to reduce those problems.

The medical technology management program participates in the organization effort early on and throughout the equipment life cycle by assessing equipment performance. Impact of risk and quality are monitored prior to purchase decision; during installation, maintenance and repair; and as indicators for disposition or replacement. Faulty design,

CAPITAL ASSET REQUEST

This form is required for all fixed asset purchases with a cost of \$500 or more.
Please type and complete all requested information.

poor manufacturing, lack of compatibility with existing technology, and mismatch with users' skills or needs can be corrected during the equipment selection and incoming inspection. On the other hand, incorrect operating procedures, the lack of a (or an inadequate) maintenance program, or faulty repair work can be corrected by failure analysis and corrective action based on information collection and an evaluation system that has been described in the JCAHO Plant, Technology, and Safety Management publication. The collection of equipment failure analysis information over several years indicates that equipment risk factor is dynamic. The dynamic equipment risk factor is a modification of a static factor that is assigned to a medical device when it first enters the equipment management program. This static factor is being modified, continuously, over its life cycle by risk factors that derive from information collected about the equipment performance experiences.

Periodically, a summary report of significant equipment-related performance is prepared. The report's data comprise elements that show

1. The ratio of completed to scheduled inspections
2. The number and percentage of devices that fail to pass the prescribed inspection
3. The number and percentage of devices for which a user's complaint was registered, even if no problem was found
4. The number and percentage of devices that show physical damage
5. Devices that were involved in an unusual event, i.e., an accident. Each element is counted as an event, and thresholds above which unsafe conditions may exist can be determined.

Each individual device has its own history and thus its own risk level. The failure elements report allows the structured progression from considering an isolated device performance to clustering equipment users' behavior and their interaction with the devices. In essence, this change is a translation of an equipment repair service into a technology management function that aids the hospital in selecting better equipment, establishing more effective users training that is proportional to measured risk, scheduling maintenance more efficiently, and prioritizing capital replacement. The trending of this information over time will guide the annual review of the effectiveness of the clinical engineering program.

The program should be complemented with a professional communication between the clinical engineer and the various manufacturers. It will result in the availability of better and safer products, less complex operation and maintenance instructions, more effective in-service training, and rapid resolution when action is needed.

A well-managed equipment program provides a systematic approach to controlling technology-related risks in all of its phases, from the needs analysis to equipment disposition. Equipment-related data elements provide qualitative criteria for evaluating equipment and users performance in relation to equipment use. Through the development of a failure analysis program, continuous improvement in equipment performance and simultaneous reduction of risk potential in the clinical environment is achievable.

Technical Asset Management

An accountable, systematic approach will assure that cost-effective, efficacious, safe, and appropriate equipment is available to meet the demands of quality patient care. Such an approach requires that resources committed to the acquisition and the management of medical equipment will be monitored. It is assumed that the financial group manages cost accounting. The medical equipment management program's purpose is to ensure that a process is dedicated to the management of technology.

The MTAC provides a comprehensive and integrated approach to the analysis, implementation, and management of new or additional medical technology. It will turn a fragmented and unpredictable decision making process into a new technique that is well conceived and that supports the hospital's mission. Bold action is required in order to achieve this, including gathering knowledge regarding the trends in medical technology; the development of decision criteria and analytical techniques; the interaction with budget strategies and financial alternatives; the implementation of the capital assets management program; the determination of facility design and long-range services impacts; and the coordination of technology and assets information into hospital operations. This technique will fill many gaps in database reports that are critical to effective operation and hospital performance. Once it becomes integrated, this process may impact a broad range of parameters, including monthly profit and loss, employee productivity, cost accounting, departmental utilization, the effect of physicians' practice patterns on resources, use of hospital resources in relation to patient outcome, analysis of charges, comparative data from other hospitals, profitability forecasts, and procedures pricing.

Asset Management

The attributes of ideal asset management are demonstrated through the continuous availability of robust and reliable equipment and systems at the lowest possible life cycle cost, whenever and wherever needed (see Chapter 35). Asset management attributes are outlined below.

1. Acquisition and equipment life cycle
 - (a) Involvement in the process of determining the need for equipment (both short- and long-term needs)
 - (b) Preparation of bid specifications and supporting negotiation
 - (c) Careful and detailed pre-purchase evaluation and selection
 - (d) Development and performance of acceptance testing
 - (e) Technical support over the equipment's life cycle
 - (f) Recommendations for, and assistance in, its disposition by replacement, refurbishment, upgrade, or declared obsolescence

2. Technical support
 - (a) Establishment of complete equipment inventory with control records, files containing operating and service manuals, and testing and quality-assurance indicators
 - (b) Incoming equipment acceptance testing and application of a control-number tag
 - (c) Hazard and recall notification and incidents handling system
 - (d) Periodic, as well as preventive, maintenance of all equipment, performed by either hospital personnel or outside vendors
 - (e) Equipment repair, including management and integration of service vendor activities
 - (f) Day-to-day assistance to equipment users promoting improvement in clinical use of equipment (e.g., periodic 'equipment rounds' in the diagnostic-imaging department)
3. Information and Training
 - (a) Dissemination of user's of manuals and other labels;
 - (b) Processing and tracking hazard and recall data
 - (c) Initial and ongoing training of all clinical personnel in the safe and effective use of patient care equipment on at least an annual basis
 - (d) Investigation of incidents, prompt reporting as appropriate, equipment-related incidents, hazards, and problems. Methods to avoid learned errors should be discussed during staff training
4. Monitoring and evaluation
 - (a) Development of, implementation of, and participation in quality assurance and risk management activities
 - (b) Periodic assessment of the equipment management program's effectiveness with the combination of objective and subjective data
 - (c) Ensuring of effective communication and feedback between relevant personnel in the hospital, (e.g., clinical staff, purchasing, clinical engineering, hospital administration, and equipment vendors). It is important to focus all service-related communication between hospital departments and vendors in the clinical engineering department.
5. Documentation of program activities described above to meet regulatory, accreditation, and problem solving requirements and to minimize liability

A clinical engineering program, through outstanding performance in equipment management, will win the support of the hospital and will be asked to be involved in the full range of technology management activities, including:

- An equipment control program that encompasses routine performance testing, inspection, periodic and preventive maintenance, on-demand repair services, incidents investigation, and actions on recalls and hazards
- Multidisciplinary involvement in equipment acquisition and replacement decisions; development of new services; and planning of new construction and major renovations, including intensive participation by clinical engineering, materials management, and finance departments
- Training programs for all users of patient care equipment
- Quality improvement (QI), as it relates to technology use
- Technology-related risk management

Clinical Engineering Needs

Because medical assets, the technology, the information, and their interaction with users are mission critical, professional management review is expected to guide this process. Clinical engineering professionals have the skills and the competency to provide this service. However, an effective program requires that administrative and clinical personnel have a clear vision of the program deliverables and return on investment. The deliverables must be well documented and periodically reported, highlighting changes in medical-assets characteristics and performance, clinical engineering personnel development and turnover rate, risk mitigation results, cost containment achieved, customer satisfaction, and participation in scientific publications.

To deliver all of these items, a clinical engineering program requires strong and capable leadership, commitment of budget for personnel, test equipment, and appropriate space. Clinical engineering leadership must be able to identify the needs for a quality program and to determine the impact if the expected level of fiscal support is not obtained. To accomplish this, workload and budget allocations per unit of service must be developed and established for the organization and for clinical engineering functions. Because medical assets management consists of a variety of tasks, individual impact and alternatives should be studied and presented to management.

A successful clinical engineering program is largely dependent on adequate budgetary support for training, administrative overhead, subscription to technical services, and access to supplies. Strong relationships with peers in other organizations, including professional societies and vendors, should be encouraged, and information technologies such as computer hardware and software programs are necessary.

Within the organization there should be a demonstration of strong support for the clinical engineering program through clear and immediate communications and involvement of members of the program in space and equipment planning, purchasing decisions, and service contract review. Organizations that have adopted this approach have harvested the benefits of planting and nourishing the seeds of optimal medical technology management.

Good Management Practice for Medical Equipment

Michael Cheng

Health Technology Management
 Ottawa, Ontario, Canada

Joseph F. Dyro

President, Biomedical Resource Group
 Setauket, NY

Establishing essential elements for good medical device technology management practices (Cheng, 1996) is desirable and is in keeping with the development of concepts of best practices or good practices standards and recommendations. In the government-regulated fields, Good Manufacturing Practice (GMP) has long been established as a quality assurance requirement for drugs, and later it was extended to medical devices regulated by the United States Food and Drug Administration (see Chapter 126). More recently, quality systems have become mandatory regulatory requirements for manufacturing medical devices in an increasing number of countries worldwide, following the recommendations by the Global Harmonization Task Force (see Chapter 124). Quality assessment and performance improvement regulations have recently been promulgated by the United States, requiring hospitals to develop and maintain a quality assessment and performance improvement (QAPI) program.

In North America and many other parts of the world, the quality assurance of professional practices is delegated to the professionals themselves (whereas it is delegated normally to their associations). Standards of practice for clinical engineers exist in Canada (see Chapter 123). Similarly, there are good distribution practice, good laboratory practice, good clinical practice, and many other “good practices.” Clinical engineers (CEs) and biomedical equipment technicians (BMETs) are professional managers of medical devices in health care institutions. Basic guides to Good Medical Device Technology Management Practices (GMDTM) or Good Management Practices (GMtP) are clearly needed.

The need for GMtP is even more urgent in developing countries for the following reasons: In developing countries, medical equipment maintenance remains an unresolved problem. Over fifteen years ago, the World Health Organization reported that 25%-50% of all equipment in hospital inventories is out of order; the situation has not improved significantly since then. In fact, the situation is complicated by the rapid global diffusion of medical devices. A GMtP could serve as a guide for CEs worldwide. Medical device maintenance is considered one component of several essential elements that constitute medical technology management (see Chapter 30). Placing maintenance within the framework of a total medical technology management system will facilitate the development and sustenance of maintenance programs. Recently, recommended practice for a medical equipment management program was developed in the United States under the aegis of the Association for the Advancement of Medical Instrumentation (AAMI) and was accepted as an American National Standards Institute (ANSI) (see Chapter 122). This was a step in the right direction, and it is a document upon which one could build a more comprehensive approach to medical technology management.

This chapter presents a proposal for a GMtP that incorporates all of the essential elements of technology management (see Chapter 30) and discusses the practical applications of such a good practices document.

Proposed Essential Elements for Management

Starting with the essential element of medical device maintenance, one can readily grasp the fact that many interrelated factors at all of the stages of the equipment life span, if left unmanaged, greatly complicate the maintenance problem. However, it is clear that if maintenance capabilities are considered during the initial stage of planning and acquisition, maintenance problems can be minimized. For a comprehensive and more effective way to manage medical equipment, one can learn from GMP by using the system approach to consider the management of the different aspects within the life cycle of a medical device. The typical life cycle of a medical device has the stages shown in Figure 31-1.

Information gathering for the planning phase normally starts during the last three phases, but it can occur at any phase of the life cycle.

Planning

Maintenance is just one element to be managed. Proper management of each of the other elements has an impact on the maintenance function, but it is especially important in the planning phase. For example, in the planning phase, one can specify the following conditions that should be met in order to aid the decision-making process:

1. Demonstrated needs and benefits
2. Available qualified users
3. Approved and reassured source of recurrent operating budget
4. Confirmed maintenance services and support
5. Adequate environment support
6. Regulatory compliance

If all of these conditions are met before the acquisition of the device, problems (including maintenance) that can occur later will be reduced. If some conditions are not met, potential problems can be anticipated rather than coming as surprises that cause wastes of precious resources as well as obvious frustration for the maintainer. The previous six conditions are simple and should be applied to any routine acquisition of a medical device. A policy on medical device acquisition that includes meeting these conditions as prerequisites to acquisition will reduce medical device problems later in the life cycle of the device. For example, a consideration of the skill level that is required for operating a device will ensure that only the appropriate technology is acquired. Similarly, assessing the financial resources of the acquiring enterprise will determine whether the total cost of operation of a device can be maintained. Items such as cost of disposables, training costs, and maintenance costs can be identified, and appropriate financial planning can ensue. Figure 31-2 shows the “Acquisition Iceberg” with most of its life cycle costs hidden from view. Planning for a large amount of medical equipment or the adoption of

Stages in the Life Cycle of a Medical Device

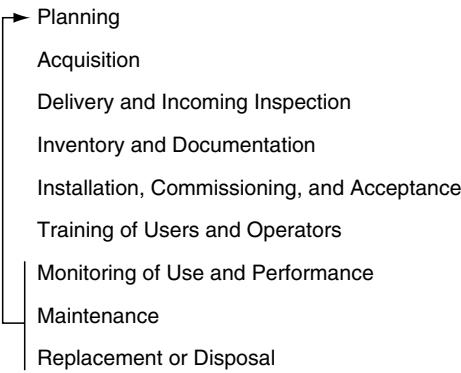

Figure 31-1 Essential elements for life-cycle management of medical devices.

Figure 31-2 Medical device acquisition iceberg.

new technology should also include a broad range of enriched considerations, as indicated in Table 31-1. The significance of managing the other phases of the life cycle is briefly introduced in the following sections, with respect to minimizing the maintenance-related problems.

Acquisition

The acquisition phase can be subdivided into evaluation (see Chapter 33) and procurement (see Chapter 34). Evaluation of devices includes such factors as safety, performance, and ease of maintenance. Such items as the need to standardize on models or manufacturers of equipment should be considered. Furthermore, in the procurement process, conditions can be included in the purchase order to specify that the supplier must supply operating and service manuals, operation and service training, and essential spare parts. Other special requirements also can be specified here, such as withholding payment if specified conditions are not met.

Delivery and Incoming Inspection

Incoming equipment should be carefully checked for possible shipment damages; compliance with specifications in the purchase order; and delivery of accessories, spare parts, and operating and services manuals (see Chapters 6, 95, and 122).

Inventory and Documentation

Medical device inventory and documentation systems can provide information to support different aspects of medical equipment management (see Chapters 35 and 36). One important aspect is consideration for standardization. Inventory entries should include accessories, spare parts, and operating and service manuals. It is advisable to make copies of the manuals for distribution to the users, while the original copies of the manuals should be stored at the technical document library for safekeeping.

Installation, Commissioning, and Acceptance

Installation and commissioning can be carried out by in-house technical staff if they are familiar with a given item of equipment. If installation and commissioning by the suppliers are needed, in-house technical staff should monitor the process so that any technical matters can be noted and recorded on the equipment service history. The occasion also provides an excellent opportunity for in-house technical staff to gain familiarity with the new item.

Training of Users and Operators

Training of users and operators is important in ensuring the safety and effectiveness of medical devices. Operator error is a leading cause of device malfunction. In developing countries, expatriate physicians frequently change equipment, and retraining before the use of complex devices should be mandatory. Incorrect use of devices also will greatly increase maintenance problems.

Monitoring of Use and Performance

One common mistake is to believe that the warranty period is covered by the supplier, so no in-house technical attention is necessary. In-house technical staff should become the link between user and supplier and should observe any supplier's technical services. Such warranty services should be recorded in the equipment service history. This also will provide a learning opportunity for the in-house technical personnel. Vigilance and the regulatory requirements of postmarket surveillance must be implemented.

Maintenance

Proper maintenance of medical equipment is essential in order to obtain sustained benefits and to preserve capital investment (see Chapter 38). Medical equipment must be maintained in working order and must be calibrated periodically for effectiveness and accuracy (see Chapter 37).

Replacement or Disposal

Given that the majority of medical equipment in developing countries is old and that spare parts are often in short supply, some old units can be dismantled to provide spare parts for similar units. This process also will provide an opportunity for cultivating technical innovation using local resources. Disposal of equipment must follow safety procedures (see Chapter 61) in order to protect people and the environment. The equipment inventory must be updated to reflect the fact that devices have been retired.

The preceding nine management functions are proposed as essential elements for good medical device technology management practices. From the simplest one-technician workshop to an elaborate national network of workshops and from the poorest country to the richest, GMtP requires the appropriate management of each phase during the life span of medical equipment.

Enrichments of the Essential Elements

The management of each phase can be enhanced when needs arise and when the resources are available. For example, the basic maintenance service is curative repair. Preventive maintenance can be added whenever time and resources become available. Further enhancement would add risk management and quality improvement. Planning, in addition to the six basic items listed previously, would include health technology assessment, national health policy, and socioeconomic considerations (see Chapter 32). Information technology can enhance one or all of the phases. Table 31-1 offers a few suggestions, but ultimately this table should include all topics associated with the management of medical devices.

Table 31-1 Enriched elements in life cycle management

<i>Essential element</i>	<i>Basic application</i>	<i>Enriched application</i>
Planning	Basic planning questions before acquisition Demonstrated needs and benefits Available qualified users Approved and reassured source of recurrent operating budget Confirmed maintenance services Adequate environmental support Regulatory compliance	Enriched tools Health technology assessment National health policy Health reform policy Socioeconomic elements Political-cultural elements Alternative health care Other considerations
Acquisition		
Delivery, incoming inspection		
Inventory and documentation	Paper or cards	Computers
Installation, commissioning, and acceptance	Risk management, quality improvement, and information technology	
Training users and operators		
Monitoring use and performance		
Maintenance	Corrective, preventive	
Replacement or disposal	Personal safety and environmental procedures	

Applications

Table 31-1 provides a framework that integrates all topics relating to medical equipment management. "High profile" topics (e.g., regulations, health technology assessment, acquisition strategy, risk management) are linked to the shop level operational elements. This holistic framework provides a "big picture" for everyone, and it can serve as a simple reminder to senior management that planning is an integral part of GMtP. In the training of new technicians, this framework is also very useful for seeing the basic elements in relation to advanced topics.

Good management practice using the life cycle approach could offer an effective management system in developing countries, to meet the challenge of the rapid global diffusion of medical technologies. It also should improve the recognition by decision makers of the tasks and skills needed by medical equipment professionals to manage medical equipment properly. The life cycle management concept was reported in a health care policy mission to Mongolia (Cheng, 1996). In the Republic of Vanuatu, national policy and guidelines for the management of medical equipment based on the life cycle management concepts were established in 2001 by the country's Ministry of Health. (Cheng 1999; MoH, 2000). Again, based on the life cycle management framework, Lao (2003) has recently established a medical equipment management policy and has presented this national policy at an international forum (World Bank, 2003).

Some medical equipment professionals in industrialized countries may claim that managing these simple essential elements is already their daily routine and there might not be a need to state the obvious. While this may be true, it further emphasizes the importance of documenting what basic good practice is. Furthermore, many CEs and BMETs have expressed their lack of involvement in the planning and acquisition aspects of medical equipment. This good management practice guide should help to legitimize their role and to gain support from senior management to include CEs and BMETs in the activities that are important to good management of medical devices.

One suggested reason for the unsatisfactory development of medical equipment management capacity in developing countries was the lack of an international standard to guide this development (World Bank, 2003). The GMtP framework can be developed into an international standard, with detailed application tools for international applications. This standard also can serve as a guideline for monitoring, evaluation, or audits in a way that is similar to the use of other quality standards. Weakness in certain areas of service can be systematically identified and strengthened in this manner.

Developing countries have expressed a need to know "how to fish" for themselves in managing medical technologies (World Bank, 2003). For many developing countries, the life cycle management framework described in this chapter and the practical maintenance strategy (see Chapter 38) can be used together systematically to manage medical equipment. No significant external resources are needed for the application of this methodology. They can serve as tools to "fish for oneself."

Health Care Strategic Planning Utilizing Technology Assessment

Nicholas Cram

Texas A&M University
College Station, TX

The effective and efficient management of medical technology has become a matter of financial survival for health care facilities. Coordinating purchases of medical equipment and medical equipment service contracts requires both technical and managerial expertise. Regardless of the size of the health care facility, the process of successfully maintaining and acquiring medical equipment remains the same. Only the economies of scale differ with regard to size. Medical technology assessment provides a management tool linked to the specific needs of a specific health care facility, as well as the mission and vision statements of that health care facility. This linking process of assessment and acquisition of medical technology is vital to long-range strategic planning. In such planning, existing and projected additions of technology within the health care system, must be evaluated to determine necessity, efficiency, safety, and cost versus benefit. Existing and newly acquired medical technology must also be evaluated with respect to the current and future needs of the health care organization. Developing a technology evaluation system that incorporates technology forecasting and off-the-shelf technology with specific needs and future goals is the most efficient way to provide a decision making template for strategic planning. Medical technology purchase decisions are often made with respect to a single department or a single event, without a systems approach or multidepartment involvement. A well-defined technology assessment program can incorporate provisions for medical device system interfacing and future growth, which is usually not a priority with the single-department approach to medical technology acquisition.

The ability to interface disparate devices with a central monitoring area and/or database is an ever-growing requirement among health care systems. Both in-house interfaces and telemedicine applications need to be considered, even if they are not currently required. Coordination of purchases through a technology development plan based on technology assessment will prevent disappointments and costly retrofits.

Standardization and economies of scale can be achieved with a system-wide approach to technology acquisition and can provide a better bottom line for the organization. The development of medical device vendor standards must include clinical and technical criteria. A lower cost product that is of poor quality and not accepted by the clinical staff could potentially jeopardize patient care. The selection of a standard product, therefore, must involve a combination of quality, effectiveness, and cost factors, all of which can be achieved with a medical technology assessment program.

The Medical Technology Assessment Process

The most robust and comprehensive method of technology assessment is known as randomized controlled clinical trials (RCTs). Although this method provides extremely useful information, the process is complicated, expensive, and time consuming. Clinical engineers (CEs) and chief technology officers (CTOs) need to have access to a continuous flow of information concerning the technology baseline and future needs of their specific organizations. Medical technology assessment (MTA) is a continuous process of evaluating the medical equipment in use, planning for future technology needs, and acquiring medical equipment. The most important and essential step in beginning a medical technology assessment program is the existence of an accurate equipment inventory. The most efficient review of equipment is provided with a computerized maintenance management system (CMMS) (see Chapter 36). A physical inventory should be taken annually and should be verified against the inventory reflected in the CMMS database.

The technology baseline is accomplished using a medical equipment audit, which consists of both an inventory and a utilization level measurement of all medical devices that

the facility is currently using. An inventory listing alone is not useful as an audit tool to establish the technology baseline. If the facility has 100 devices listed on the inventory, and 50 are never used due to either maintenance problems or user preference, the actual technology baseline should reflect this fact. As an example, during a preventive maintenance check of infusion pumps, the CE finds several of the items stuffed in the corner of the soiled hold room. Upon investigation, the CE learns that the nursing staff has not used the pumps in six months because they did not understand the programming features of the pumps. The solution is to determine whether operator training in-service will solve the problem or whether the technology is so complicated that it is not user friendly. In either case, the actual utilization of the equipment must be reflected in the technology baseline, which is accomplished with the technology audit.

Planning for the future technology needs of the organization is based on patient surveys, mission and vision statements, and demographical information of the medical population served. An integrated, interdepartmental committee with representation from clinical engineering, nursing, medical staff, purchasing, and administration provides the best results for defining and implementing the future technology needs of the organization. As with all programs, support of the medical technology assessment process must come from upper administration in order to receive the resources needed for it to be successful. Because of the importance of technology management in relation to competitive positioning, and because of the effect of technology costs on the bottom line, many health care organizations have created the position of Chief Technology Officer (CTO). In organizations with a CTO, medical technology assessment is a primary focus of one individual. In larger organizations, the chief technology officer (CTO) is typically the technology committee chair.

Acquisition of medical technology (i.e., medical devices) will be determined by the technology baseline of the facility and the needs of the organization, which are determined by the technology planning committee. Medical technology assessment (MTA) of new equipment can be accomplished through in-house resources of the clinical engineering department and clinical staff or through secondary sources. Certain devices, such as those used in imaging, are not appropriate candidates for in-house evaluations due to size and portability restrictions. Site visits and secondary sources provide the best means of MTA for devices in this category.

Technical and clinical in-house evaluations are limited in scope but can provide valuable hands-on assessment of specific devices, that cannot be achieved through any other methods. The in-house assessment process can be accomplished using a weighted matrix or ranking system for decision making. A weighted matrix is a comparison of a vendor's ability to meet certain preselected criteria. The weighting occurs due to valuing the criteria at different levels ("points"), depending on their priority. A weighted matrix is valuable in selecting the best equipment to purchase for the specific area of priority. This process is similar to that provided by *Consumer Reports* magazine in comparing various manufacturers' products. An example of a weighted matrix is illustrated in Table 32-1, in which a point system (0-5) is used to evaluate the various features of four telemetry systems considered for purchase. Table 32-2 shows an example of a report to a technology committee, based upon the results of the clinical evaluation shown in Table 32-1, in which advantages and disadvantages of the four systems under consideration are summarized.

A ranking system helps to focus on a particular area of technology. For instance, if a certain amount of capital budget money is set aside for technology acquisition in the upcoming year, a ranking system can set priorities for how much and where that money is spent. Secondary sources of information include published data, peer group shared information, group purchasing organization (GPO) flyers, manufacturer inquiries, and subscriptions from private and governmental organizations. A full discussion of MTA is presented elsewhere (David and Judd, 1993) and in other chapters of this handbook (see Chapters 30 and 33). But a brief overview of the in-house evaluation process and secondary MTA resources will be provided to allow continuity of the topic.

In-House Clinical and Technical Evaluations

An in-house clinical evaluation of new medical equipment should never be confused with a clinical trial. A clinical trial involves medical devices, that have not been cleared for commercialization by the Food and Drug Administration (FDA) under paragraph 510(k) of the Medical Devices Amendments of 1976 (see Chapter 126). These devices may be part of a study to obtain FDA premarket approval (PMA). In-house clinical evaluations, on the other hand, are performed with medical devices already in production by medical device manufacturers. The in-house clinical evaluation process uses nursing and/or clinical staff members, for evaluation of the new technology over several days as a part of their normal clinical practice or nursing protocol. As mentioned earlier, criteria are selected for the weighted matrix, and the clinical staff will evaluate each vendor against the others, based on the criteria. Clinical criteria should relate to clinical issues and user-friendliness of the equipment. Examples of clinical criteria include monitor visibility, range and clarity of signal, ability to program the device, and human-factors elements. Human-factors elements are related to features on the medical device that are related to user-friendliness. For example, if a bedside monitor requires three steps in order to print an ECG strip, is the three step process intuitive? Does it require that a blue button be pressed, and then a red button? Is the system Windows®-based? Is there a point-and-click process similar to those of personal computer (PC) processes? How quickly did the nursing staff learn how to use this new medical device after the initial presentation? The clinical evaluation is designed for selection of the medical device that best suits the clinical (i.e., patient care related) needs of the clinical staff, regardless of the price. Therefore, relative vendor pricing never should be disclosed to the clinical staff until after the evaluation process is completed.

The in-house technical evaluation should involve maintenance and interface related criteria such as mean time between failures, nonproprietary features of hardware and software, cost of parts, cost of the system, cost of ancillary parts (e.g., cables, pads, electrodes), installation requirements, ability to be upgraded, scalability, and the cost and availability of technical and clinical training. It should be noted that the criteria for in-house technical and clinical evaluations also could serve as selection criteria for information received from secondary sources of MTA.

TOTAL POINTS	38	26	27.6	29.5

Criteria scored 0-5, except "reputation of vendor" 0-10, with 5 and 10 as best scores respectively

Planning Strategies

The format for MTA presented in this chapter is an expanded version of the approach of ECRI, a long-time advocate of medical technology management and strategic technology planning (ECRI, 1989; ECRI, 1992). All planning strategies must have the support of upper management in order to be successful. This support must include budgetary resources required to carry out the plan. As in the case of MTA, the medical technology strategic plan is long-range (i.e., 5 or more years) and is continually evolving. The plan should be updated at least annually.

Two key elements of the technology strategic plan are the technology audit and the community needs assessment. The technology audit provides a technology baseline for a specific facility. In essence, this is the technology snapshot of where a facility is today. The community needs assessment provides essential information regarding potential opportunities for expanded health care services among a specific patient population. The community needs assessment provides a *technology vision* of where a

Table 32-2 Technology assessment: Final report to technology committee

Company 1 (\$198,000)	Company 2 (\$217,000)
Advantages: 1. Price 2. Best score for both clinical and technical evaluations 3. Committed to research and development 4. Technical and clinical training provided 5. Full disclosure system Disadvantages: 1. Lesser-known company; no track record 2. Not an OEM; reseller of device	Advantages: 1. Price includes two portable monitors for transport 2. Not user-friendly Disadvantages: 1. No ST segment analysis 2. Upgrades depend on agreements with another company 3. No technical or clinical training 4. Not an OEM; reseller of device
Company 3 (\$225,000)	Company 4 (\$349,000)
Advantages: 1. Excellent vendor reputation 2. System operates in UHF range for improved signal quality Disadvantages: 1. Not user-friendly 2. Not PC-based 3. Worst overall score on clinical evaluations	Advantages: 1. Best score on clinical evaluations 2. User-friendly Disadvantages: 1. Price 2. No clinical or technical training provided 3. Unknown vendor reputation

health care facility should position itself. Combined with demographic information, the community needs assessment and the technology audit are powerful tools for strategic technology planning.

The sole purpose of the medical technology strategic plan is to support the clinical strategy of the health care facility. The medical technology strategic plan therefore must have balanced input from both clinical and technology sectors of the health care facility. Valuable first-hand information can be obtained from the technology audit. Additional clinical input can be obtained through a committee setting or face-to-face interviews with key decision makers in your facility.

The medical technology strategic plan is a marriage of convenience. The clinical goals and clinical strategy are compared to the baseline technology provided by the technology audit, and the basic question is posed: How do we get there from here? It may require the purchase of new medical devices, or there may be a need to support a completely new technology. An awareness of emerging technology should always be incorporated into the medical technology strategic plan. There will be an increasing trend in health care technology for software-driven applications, including remote diagnostic procedures for medical devices, robotics, and electronic records automation. Although the exact impact of biomedical research might not be predictable, clearly noninvasive and minimally invasive procedures are on the rise. Changes in your health care facility's infrastructure must be considered today in order to avoid costly renovations or missed opportunities in the future. Since all planning involves futuristic targets, there will always be a risk of unknown events or circumstances, which have an impact on the planning process.

Planning must be a fluid process that is flexible enough to allow for change. Risks can be minimized by thorough research, and specific contingency plans should be provided for suspect critical elements of any strategic plan. Attending professional conferences and subscribing to professional journals will provide adequate information on emerging technology and health care trends. The Internet is a rich source of emerging technology information. All facility strategic plans should support and complement the mission and vision statements of the organization. Figure 32-1 provides an illustration of a flow chart for a technology strategic plan.

Utilization of Automated Systems

The flow of information for any clinical of engineering process can be overwhelming. Coordinating, reviewing, and implementing of process changes are best accomplished using automated systems. Manual methods of reviewing and sorting mountains of infor-

mation are inefficient and not practical. Most computerized maintenance management systems (CMMS) provide user-defined fields. The CMMS provides a database of all medical equipment in the system. CMMS reporting and trending capabilities provide complete maintenance histories of all medical devices in the system. Cost benefit and equipment life cycle calculations can be derived from user-defined fields in the CMMS. A user-defined field allows the system user to create analysis reports, which automatically update the status of priority areas. The priority areas are flagged in the CMMS according to indicators identified by the user. An indicator is defined as a quality characteristic of a process that can be measured and contributes positively or negatively to an outcome. Indicators are best identified when a process is detailed in a flow chart. An example of a process flow chart with identified indicators is illustrated in Figure 32-2.

Defining Terms

Chief technology officer (CTO): An organizational position that is responsible for the management, application, and strategic planning of all technology within the organization.

Community-needs assessment: A survey or questionnaire that provides essential information regarding potential opportunities for expanded health care services among your specific patient population. The community-needs assessment provides a technology vision of where your health care facility should position itself.

Indicator: A quality characteristic of a process that can be measured and contributes positively or negatively to an outcome.

In-house clinical Evaluations: An assessment process used in medical technology assessment that uses facility patient care staff for hands-on analysis of medical equipment in a pre-purchase scenario.

In-house technical evaluations: An assessment process used in medical technology assessment that uses facility technical (Clinical Engineering) staff for hands-on analysis of medical equipment in a pre-purchase scenario.

Medical technology assessment (MTA): A management tool linked to the specific needs of a specific health care facility, as well as the mission and vision statements of that health care facility. A continual process of assessment and acquisition of medical technology is vital to long-range planning. Existing and projected additions of technology within the health care system must be evaluated to determine necessity, efficiency, safety, and cost/benefit. Existing and newly acquired medical technology also must be evaluated with respect to the current and future needs of the health care organization.

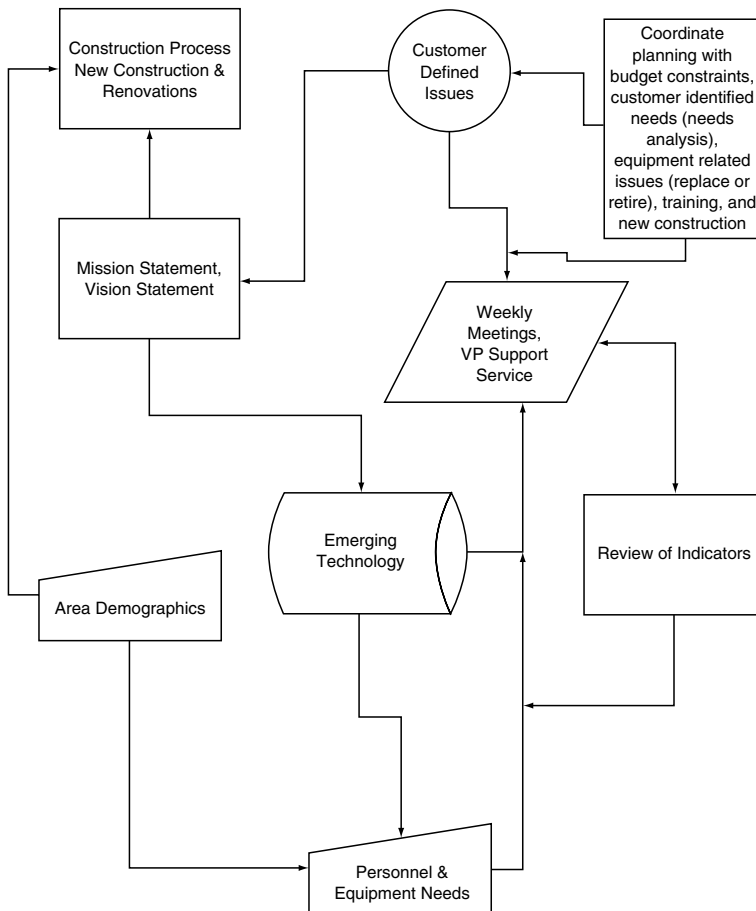

Figure 32-1 Clinical engineering and telecommunications strategic planning process.

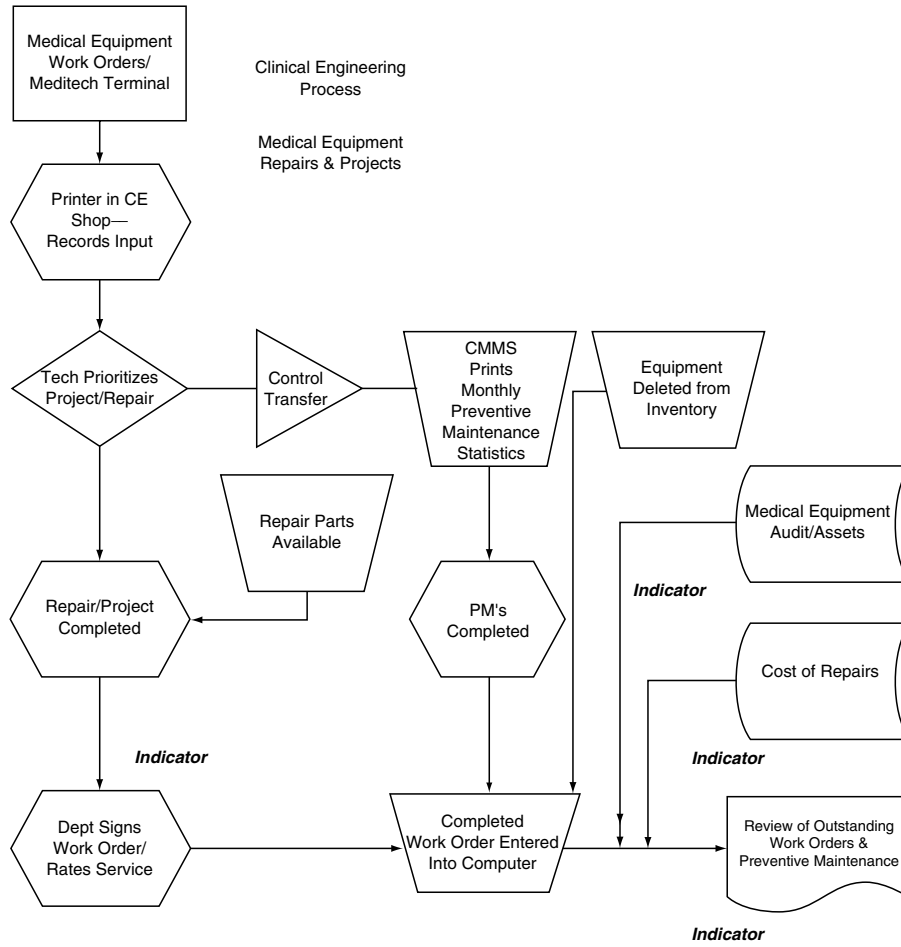

Figure 32-2 Flow chart of a clinical engineering process, medical equipment repairs and projects, showing four indicators: Repair/project completed, medical equipment audit/assets, cost of repairs, and review of outstanding work orders and percentage of completed preventive maintenance procedures.

Technology Evaluation

Gary H. Harding

Greener Pastures, Inc.
Durango, CO

Alice L. Epstein

CNA HealthPro
Durango, CO

Participation by clinical engineers in the evaluation of technology can directly contribute to and affect the quality of patient care and patient outcomes and financial situation of the facility. The extent of training required to effectively participate in the process and the workloads of various department required to contribute will need to be analyzed. The impact of new or reengineered technologies varies from the time the technology is introduced through its obsolescence. Technology evaluation is most often associated with complex devices, but clinical engineers should be aware that what appear to be simple, noncomplex devices should be subject to the same technology evaluation processes; otherwise, there can be dramatic and negative impacts. Technology evaluation is not merely the review of devices or supplies, but the review of those devices or supplies for particular clinical need(s). If the technology selected does not meet the clinical needs of the patient or cannot be successfully used by those who are responsible for direct patient care, then needed or optimum procedures could be impossible to provide. If the technology overlaps the utility of existing equipment or is rapidly made obsolete by other technology expected to be introduced onto the commercial market, there can be a substantial negative financial impact. If user and service support are not considered, frequent training and retraining in correct use of the technology and mitigation of accidents, as well as constant down time for repair or maintenance, can result.

Clinical engineering's contribution to careful and complete evaluation of technology can ensure that the introduction of new technology meets the medical goals of the organization in the present and, to the extent possible through forecasting, in the future. Examining ways in which technology would integrate system-wide into the organization, or what alternatives there are or might be in the near future, can help to control costs, thereby improving the organization's financial situation. Determining whether and how technology can be rapidly assimilated by clinical staff and whether service expectations are within reason and acceptability can reduce training requirements, accidents, and down time.

This chapter will discuss many of the critical aspects of technology evaluation. Evaluation of technology is a team effort. Members of the clinical staff, administrative management, facilities management, and many others should (and do) participate in this process. As with all team efforts, there will have to be concessions because of such things as cost and user limitations. While there are many acceptable and necessary reasons to make concessions, clinical engineers must be careful to identify and to evaluate requested concessions that do the following:

- Impact patient and/or staff safety
- Are not truly required, as the limitation is perceived and not real
- Have potentially severe utility or financial implications
- Fail to meet laws, regulations, or acceptable practice

Evaluating technology can be a challenging and rewarding experience for the clinical engineer—one in which others can learn from the engineer, and the engineer can learn from others.

Strategic Technology Planning

Where does (or should) an organization start in the technology evaluation process? Because of the importance of technology to the overall patient care and financial goals of the organization and the risks of haphazard acquisition, the first step in technology evaluation should be development and implementation of a strategic technology planning program (or process, depending on the size and resources of the organization) (Cram 2003). The main purpose of strategic technology planning is to:

Gain a complete understanding of the existing technology-related equipment and services within the organization and the expected progression of and changes in services that can be forecast with an intent to provide a base on which to consider and time acquisition of future technology.

The clinical engineer has the primary responsibility for identifying existing technology within the organization. This duty often takes the form of the clinical engineering inventory, although it is not uncommon to supplement this with inventories from specialty departments such as radiology and clinical laboratory, and from capital equipment financial bases, e.g., accounting. For the purposes of strategic technology planning, a complete tabulation of current technology should be developed and should include not only the name and manufacturer, but also the age and expected useful lifetime. Other information (e.g., location in the facility and progressive annual costs to use and maintain) can be useful as well, although more detailed information can be acquired later in the process as specific technologies are considered. The importance of this tabulation is primarily to assist in determining the status of current technology within the organization that may or may not be in actual clinical use, vendors that have supplied technology, and technology approaching obsolescence and need for replacement.

An inventory and overview of technology-related clinical services delivered by the organization is typically the responsibility of administrative management. It might include departmental administrators and/or clinicians. It is important that an overview of current technology-related services be compiled so that (1) future requests for new services can be compared against services already provided; and (2) future requests for new technology acquisition can be examined for ability to meet current needs and to expand utilization in areas other than that of the requester. It would be unwise to purchase a new surgical laser for one department when there was an existing, acceptable surgical laser in use by another department that was underutilized, for example. It would be important to know that a request for new service by one medical specialty is a service already provided by a different medical specialty, or that a technology requested for one procedure could be used in many more. Technology relating to imaging illustrates this point. Efforts by the Agency for Health Care Research and Quality (AHRQ) in 2001 included evaluating Positron Emission Tomography not only for its application in diagnosis of breast cancer, but for myocardial viability, soft tissue sarcoma, thyroid cancer, and Alzheimer's disease. Once the existing technology and services are compiled, requests for replacement or acquisition of new technology can be pursued.

In order to ensure that the strategic technology planning process is supported, it is important to seek participation by affected parties. It is not essential that all parties be represented in, for example, a strategic technology planning and acquisition committee, but some mechanism(s) to ensure that the voices of affected parties are heard and that rationales for decisions are distributed to these parties must be provided. There will be difficult, and often political, decisions about replacement, supplementation, and introduction of technology that be necessary to make. In today's economy, financial resources are limited and must be distributed carefully. Unrealistic requests may be made; powerful participants may not understand the relative importance of their need or desire versus the relative importance of another participant's need outside their expertise. One value of the strategic technology planning process is that participants can be advised of all of the needs and the rationales for decisions. Experience shows that these highly trained and motivated participants typically endorse decisions or offer constructive alternatives when provided with valid information. Organizations might want to consider utilizing independent consultants for initial process development and periodic participation in lieu of developing their own structure for strategic technology planning.

Technology and Alternatives

Once the strategic technology planning program has been instituted and identification of technologies for consideration for acquisition occurs, the process of technology evaluation can proceed. The first step in the process is to identify and assess the requested technology and alternative technologies already in use within the organization or available commercially that could meet the identified clinical need. This process will formalize the following:

1. Identification and detailing of the clinical procedure(s) for which the requester intends use of the technology
2. Collection of information about the specific technology being requested
3. Identification of other clinical procedures for which the technology could be used
4. Collection of information about alternative technologies that could be used for the same clinical procedures
5. Comparison of the requested and alternative technologies to the existing technologies within the organization
6. Determination of the risks and hazards associated with the use of the requested and alternative technologies
7. Examination of the clinical efficacy of the requested and alternative technologies
8. Performance of a conceptual needs analysis based on all of this information

Clinical Procedures

It is typical for there to be an official or unofficial clinical sponsor or advocate for acquisition of the technology. The sponsor should provide a narrative and supporting literature (e.g., authoritative published reviews of the procedures and use of the technology) for the technology being requested. The narrative should provide the sponsor's understanding of the clinical procedures for which the technology may be used now and in the future; their analysis of the clinical literature that clearly supports the use of the technology in these clinical procedures; the technology they are currently using or could use to perform these clinical procedures; and their reasons why the specific technology should be acquired. Complete copies of authoritative published reviews are desirable. A review is an article that examines experience derived from many studies; these reviews often can save those who are responsible for making decisions from having to seek out, select, obtain, and read volumes of separate articles—all of which may have individual limitations in their performance and application. Reviews often provide detailed bibliographies that provide additional references in one place and also provide the reviewer with an idea of how well established and analyzed the technology is. For example, if no reviews exist, or only three articles exist in the world, or all articles are foreign-based, the reviewer could gather important information on which additional questions to ask.

The sponsor also might be aware of, or might seek out, information about other clinical procedures for which current technology, requested technology, and alternative technology may be used. Resources that are readily available for the sponsor in this endeavor include peer-reviewed literature, the medical director and medical staff, and the manufacturer(s) of the technologies.

Comparing Requested and Alternative Technologies

The clinical engineer is well prepared to direct the effort to collect information about the requested technology and alternative technologies. A literature search should be performed emphasizing the specific technologies and include related medical literature, as well as engineering, financial, and governmental databases (see Chapter 86). Resources that identify manufacturers of the technologies (e.g., group purchasing lists of acceptable equipment, Medical Device Register (MDR, 2003), the Health Devices Sourcebook (ECRI, 2003), and MD Buyline (MD Buyline, 2003)), should be consulted. Requests for information should be made to each manufacturer of the requested and alternative technologies, emphasizing that the manufacturer should provide all information, e.g., brochures, user manuals, sales and marketing documents, support documents, and published articles that the manufacturer believes the organization should consult before making a decision about the technology acquisition. Organizations could specifically ask each manufacturer to provide a comparison of their product to that of its competitors. Such a comparison should be readily available or easily compiled, as it is important for sales and marketing professionals to differentiate their product from those of competitors. It is convenient at this time to request data that the manufacturer either submitted to the FDA (see Chapter 126) or identified to the FDA as available to support the manufacturers' contention that the technology is safe and effective for its intended purposes, as well as a compilation of the clinical procedures that the manufacturer identifies as an intended purpose of the device. In new or developing technologies, it is worthwhile to ask specifically which clinical procedures normally encountered within the medical specialties for which the technology is used are not currently within the intended purposes of the technology.

Comparing Owned vs. Requested or Alternative Technologies

Once information about possible clinical procedures and technologies has been received, and before any other extensive investment of time or money, the information should be reviewed and compared against comparable information on technology that is already owned. All affected parties should be consulted, and their viewpoints should be considered. While much of the discussion might have occurred as part of the strategic technology planning process, this effort provides an opportunity for parties to become aware of the latest information about requested and alternative technologies and how they could impact on, or be utilized by, all parties. Identification of potentially unacceptable financial impact or equipment compatibility issues could arise. Participants from other medical specialties can identify an opportunity and interest in supporting and using the technology if, for example, necessary options for their specialty are purchased; this can be particularly important to the original sponsor if the sponsor's utilization projections are marginal. A rational decision to forgo acquisition of the requested or alternative technology, to use or upgrade existing technology, or to proceed with the process as existent or modified can be made.

Risks, Hazards, and Clinical Efficacy

It is important to remember a basic premise in health care: First, do no harm. In order to meet this basic premise, potential risk must be identified. While adverse clinical events

occur, and some might be inevitable given the complex nature of medicine, unnecessary complications and accidents should be avoided when possible. It is imperative that risks be minimized and eliminated where possible through the proactive identification of risks and hazards to identify whether and how they can be mitigated (see Chapter 56).

Process

Most engineers are familiar with standard design engineering practices, such as Failure Modes and Effects Analysis (FMEA) (Stamatis, 1995). One can consider technology risk and hazard analysis to be analogous to a system-wide process applied to the technology rather than the device (Stalhandske et al., 2003). The points are the same: Eliminate unnecessary failure modes; guard against those that cannot be eliminated for some reason; and warn about those that cannot be eliminated and where guarding alone is insufficient to mitigate the risk or hazard. Elimination of risk or hazard could mean redesigning a feature of the product while in device design. In technology evaluation, elimination could mean discontinuing consideration of a product from a specific manufacturer. Similarly, while in device design, a fail-safe limit switch may be provided to guard against the potential for limb entrapment; in technology evaluation, however, the guard might be accepting products only from vendors who have a commercially available system that has been in place in other facilities for some time, without resultant adverse occurrences. Furthermore, while a caution label could serve as the warning in device design, alerting medical staff to limitations in use of each of the technologies under consideration could be an analogous technology evaluation warning. Hence, it is important that a systematic, unbiased process of risk and hazard identification and mitigation be used for technology evaluation. While the process can be identified by many names and the features vary somewhat from process to process, the goals of the risk and hazard analysis process should be the same.

Financial Risk

Risk, for the purposes of technology evaluation, means not only the risk of physical injury or facility damage typically recognized, by clinical engineers, but also financial risks that the technology may pose as well, e.g., underutilization, unacceptable dedication of financial resources, loss of clinical specialists, increase in liability premiums or potential losses, or negative publicity. While addressing certain risks would be beyond their ability or control, clinical engineers can ensure that a participant in the process who can address them is responsible to identify and review risks and their extent. While any aspect of technology evaluation can be a "make or break" item, more often decisions are based on a comparison of many aspects, with financial risk being significant.

Resources

Unfortunately, the governmental agency that we often think of as being responsible for ensuring the safety and efficacy of medical products, the United States Food and Drug Administration (FDA) Center for Devices and Radiological Health (CDRH), has a history of poor performance in this regard, as demonstrated by the number of patient and staff injuries caused by medical devices. While physicians and other medical specialists often believe that if a product has gone through the FDA process it is safe and effective, the reality is that for many device types, and in many cases, the FDA process does not determine safety and efficacy. Due to human and financial resource limitations primarily imposed by Congress, the FDA often relies on the manufacturer of the product to determine safety and efficacy. In the 510(k) premarket clearance process, the FDA often does not even require the manufacturer to provide the data on which the manufacturer made its determination that the product was safe and effective. Hence, potential purchasers of technology cannot, and should not, rely on a manufacturer or a technology having received FDA clearance to market the technology as any indication that the product is safe and effective. Greater assurance is provided if that product has gone through the premarket approval (PMA) process, usually reserved for Class III, complicated, or other technologies identified in the past as particularly problematic.

The FDA process can be abused by manufacturers, distributors, and others as a means, for example, to avoid cost, dissemination of information, or appearance of acceptance of responsibility to determine safety and efficacy. For example, a large manufacturer who held and still holds major market share in injection and blood-collection needle products did not perform unbiased, statistically significant clinical studies prior to, or for years after, placing its safety products on the market to determine that these safety products actually reduced the occurrence of accidental needle sticks. Instead, the manufacturer made it a de facto responsibility of each organization to determine on its own whether the safety products were "safe and effective."¹ CDRH cleared such products from this and other manufacturers again and again, for years, without review of safety data or even requesting that the data be provided to them.

While organizations should request this information from the manufacturer and should examine FDA and/or CDRH databases,² a healthy degree of skepticism in findings, or the lack thereof, could be warranted. If the manufacturer did not submit clinical data to the CDRH and does not provide this data in response to the request by the organization, it is difficult to offer a valid reason to continue to consider that device. It is reasonable to expect that the manufacturer is most knowledgeable (i.e., expert) about the product and its safety and efficacy. If a manufacturer cannot, does not, or will not provide substantiating information that is convincing, it is reasonable to exclude that manufacturer's technology. If a manufacturer transfers the responsibility for determining safety and efficacy to the organization, it is reasonable to exclude that manufacturer's technology from

¹This manufacturer introduced a safety-needle product in 1988. However, it was not until Younger et al. (1992), the CDC (1996), and Mendelsohn (1998) performed studies that clinical safety and efficacy of safety devices were evaluated.

²The CRDH website has databases relating to registration of the manufacturer, listing of devices, 510(k)s, PMAs, and occurrence reports, which can be accessed at <http://www.fda.gov/cdrh/databases.html>.

further consideration. Document the situation so it can be conveyed to the clinical sponsor in an unbiased, straightforward manner.

There are other governmental and private agencies that can offer information on technology evaluation. For example, the Agency for Health Care Research and Quality (AHRQ) performs technology assessments on behalf of the Center for Medicare & Medicaid Services (CMS) for the purpose of CMS determining whether Medicare/Medicaid will provide financial reimbursement for application of the technology. The AHRQ has performed a number of technology assessments since 1990.³ AHRQ states that it (or its evidence-based practice centers) uses state-of-the-art methodologies for assessing the clinical utility of medical interventions. Reportedly, their assessments are based on a systematic review of the literature, along with appropriate qualitative and quantitative methods of synthesizing data from multiple studies. While useful information can be gained from studies performed by, or on behalf of, AHRQ and CMS, it is important to differentiate the interests and motivation of the organization from the interests and motivation of a governmental agency impacting on government spending. If third-party or Medicare reimbursement is an important financial aspect of the technology acquisition, and the technology is not covered, this would be important information to acquire, document, and distribute.

The International Network of Agencies for Health Technology Assessment (INAHTA) currently includes 39 member agencies from 20 countries around the world. It offers a database of technology assessments, a technology assessment checklist, and links to member technology assessment sites.⁴ A number of private World Health Organization (WHO) collaborating agencies (e.g., ECRI) are included. If a technology under consideration is new or “cutting edge” technology in the United States, experience gained by use in other countries can be obtained by accessing INAHTA information.

Private agencies, such as ECRI, can offer technology assessment information of varying detail (Keller, 2003). While this information is typically fee-based (e.g., cost per report and cost per annual subscription), it can be a wise investment if the resource provides specific, detailed information about the requested or alternative technologies under consideration that is correct and unbiased. In some instances, fees cover telephone consultation with agency experts to whom specific questions can be addressed. On-site and comprehensive consulting services also can be useful, especially where organizational expertise does not exist or where organizational internal dynamics challenge the ability for the system to operate properly otherwise.

Local, regional, national, and international organizations of clinical engineers can provide a mechanism for obtaining advice from peers who may have encountered the same technology evaluation issue. (See Chapters 130, 131, and 132).

Conceptual Needs Analysis

The purpose of the conceptual needs analysis is to capture and synthesize clinical procedure and technology information that is pertinent to decisions making. That is, it is not typically reasonable to provide participants with a package of original articles, manufacturers’ brochures, or technology assessments. A small, experienced taskforce should preview the information and present only the information that is necessary to do the following:

1. Educate the participants
2. Inform participants why preliminary procedures, technologies, or even specific vendors have been excluded from further consideration
3. Briefly identify aspects that are similar to all technologies under consideration
4. Identify in greater detail specific aspects that are dissimilar and that are important to decision making
5. Identify known risks and hazards and methods to successfully mitigate them⁵
6. Detail the clinical efficacy of the technologies

Some organizations may direct this task force to make specific recommendations based on their analysis of these considerations.

The preliminary analysis should be provided to all participants in anticipation of their individual or collective (i.e., committee) review. Ample time for participants to examine and consider the information must be provided. Participants may pose new questions that will have to be explored. Collective review allows an opportunity for discussion and the back and forth consideration of important items, be they financial, technical, or administrative. The desired outcome of the conceptual needs analysis is to determine whether existing, requested, or alternative technologies should receive further consideration. If the outcome is not to proceed, it is important to document the reasons for discontinuing pursuit; this may be especially important when the issue was related to replacing existing equipment that is nearing obsolescence. Documenting the decision can simplify future consideration if and when it arises; this is not to say future consideration will be avoided or result in the same outcome, since reasons for discontinuing pursuit may have been overcome at a later date. It can help the organization’s litigation position if there are valid reasons for discontinuing pursuit and if an incident occurs with the current equipment.

Several other important decisions can be made at this juncture:

- Which top three to five vendors should be considered further?
- Should the technology receive further evaluation of only the preliminary clinical procedures that were identified, or should a broader or narrower application be pursued?
- Are there other issues (e.g., potential physical location, staffing, volume of disposables, and medical professional certification) that must be considered, and how critical are they to ultimate acquisition and safe introduction of the technology?

- How well does the technology fit into the current user environment? (Can the technology be expected to fit easily, safely, and reliably into current experience and practices of clinical users, service support professionals, and the patient population without undue resistance or extraordinary requirements for training?)

Assuming that a decision is made to pursue the technology further, the next step involves determining desired specifications and starting the bid process. As the bid process is an important and complex step, it is discussed in this handbook separately in the next chapter (Chapter 34). This technology evaluation model assumes that desired specifications have been identified and that a reasonable bid process has been achieved. The remaining discussion assumes that the bid process was performed and that it resulted in a further reduction of vendors and identification of a more detailed compilation of device features and options, service support offerings, acquisition alternatives, and training requirements.

Testing Laboratory and Engineering Evaluation

The most desirable next step is to have the remaining vendor products brought into the facility for further evaluation. If possible, the technology or a representative sample thereof (e.g., a single patient monitor) should be delivered by each vendor to the facility. In some cases, where the equipment is extremely large or costly, or requires special utilities or facilities, this may not be possible. In such cases, the testing laboratory and engineering evaluation should be performed either at the manufacturer’s location or in a representative installation at a time when the technology is not expected to be in use. It is important that those who are responsible for the laboratory and engineering evaluation receive adequate training from the manufacturer prior to the actual evaluation. It is also essential—especially when the testing of equipment is performed in a representative installation—to advise the vendor of tests that are expected to be performed prior to their performance, in order to allow the vendor to identify tests that could be potentially destructive to the equipment or harmful to staff.

Laboratory and engineering evaluation prior to introduction of the technology serves several purposes. Of primary importance is the keeping of potentially unsafe equipment out of clinical areas. It is important to examine the quality, features, performance, possible failures, and service requirements of the equipment as well.

Incoming Inspection

Technology entering a facility on a trial or evaluation basis should be subjected to full incoming inspection testing (see Chapters 6 and 122). Because the clinical engineering components of the evaluation are significant, the tests performed during incoming inspection of a trial/evaluation device should be even more comprehensive. Clinical engineers are expected to gain information that will allow decision makers to differentiate and decide among competing products. While incoming inspection of a purchased product can focus in part on verifying that operation specifications are met, incoming inspection of a trial/evaluation product could justifiably focus on determining the full range of operation and the comparability of operation from one trial/evaluation product to another.

Clinical engineers have a multitude of incoming inspection checklists available,⁶ including the manufacturers’ recommendations on how to examine electrical and mechanical safety of the products. Most address classic aspects of electrical and mechanical safety through inspection and testing. All accessories required for proper operation should be present, as should the operators’ manuals and technical service manuals and schematics. Some manufacturers might attempt to limit this information, but the information is important to understanding exactly how the product works and the limitations that are inherent. User/operations and service manuals, like the product and options, can be returned to the manufacturer if their product is not selected, thereby avoiding cost to the manufacturer or release of information that the manufacturer considers proprietary and sensitive.

Proper operation of the equipment as specified in the performance specifications in the manufacturer’s literature should be confirmed. However, if possible, clinical engineering should develop and perform tests that are specifically intended to differentiate competing products in important areas. Tests that differentiate equipment but that are not clinically significant or not significant in any other way (e.g., safety-wise or financially) should be avoided.

The clinical engineer should note whether the product has been evaluated in any manner by nationally recognized testing entities; e.g., Underwriters Laboratories (UL), Canadian Standards Association (CSA), or City of Los Angeles. The clinical engineer should acquire and peruse all applicable standards that address the technology under evaluation (see Chapters 117, 118, and 125). Further, it should be noted whether the product does or does not comply with governmental labeling and performance requirements; e.g., use on physician prescription only and OSHA-compliant for reducing accidental needle sticks.

Gaining the Experience of Others

Clinical engineers should require the manufacturer to provide references, including customers who currently utilize the product. They should contact these references directly, to discuss the reference’s experience with the product and the vendor. Clinical engineers should contact their counterpart(s) within the reference organization(s) to seek their input on their experiences, whenever possible. If available to them, clinical engineers should contact others not included in the manufacturer’s reference list who have experience with the product. Such lists might be available through group purchasing organizations, professional societies, and shared service organizations. Clinical engineers should be willing to contact representatives from other organizations who have noted use of the product in, for example, the medical literature. When gaining the experience of others, however, it is

³A list of, and access to, these reports can be found at <http://www.ahrq.gov/clinic/techix.htm>

⁴Go to <http://www.inahta.org/>

⁵It is important to recognize that mitigation may not mean elimination of the risk, but, for example, implementation of risk, control actions or purchasing insurance to cover the risk.

⁶One example is the ECRI Inspection and Preventive Maintenance Manual.

important to remember to compare, to the extent possible, “oranges to oranges.” Experience with a product that might be years older than the product under evaluation can result in misinformation if the clinical engineer is not careful. Similarly, comparing a vendor’s historical performance to its current performance might not be appropriate, in either a positive or a negative way. The clinical engineer should examine the information and its limitations, with an emphasis on determining exactly what can be said and supported with regard to positive and negative aspects of the experience of others.

Technology and the Facility

Will the facility be a good fit for the technology? The clinical engineer has the user’s manual, the service manual, the schematics, and, most importantly, the product. Most clinical engineers have a working knowledge of the physical facilities in which the product can be used and of the utilities necessary to support the technology. Certainly there might be other engineering professionals who have greater expertise and responsibility for the facilities and utilities. However, laboratory and engineering evaluation of the products is a perfect opportunity for clinical engineers to examine and discuss, with their internal counterparts who are responsible for the facility, what the perceived needs are for the product. For example, there might be special power or shielding requirements. There might be special water, gas, or other requirements. Systems (e.g., fire suppression systems, to protect the physical product) might be required. The device might be too large to fit into the facility, or it might be too heavy for the support structure. The facilities engineer should be invited to participate in the laboratory and engineering evaluation. More than one strong alliance between clinical engineers and facilities engineers has been created by clinical engineers recognizing the facilities engineer’s expertise and encouraging participation.

Maintenance and Service Requirements

The clinical engineer can examine and perform manufacturer-identified maintenance and service procedures to determine human and financial resources that are required. The ease of disassembly and the need for special tools can be examined. The clinical engineer can evaluate whether special training is required and whether the manufacturer can and will provide such training. But there are other issues that might be more difficult to evaluate. For example, how reliable is the product? What are the expected maintenance and service requirements? While the results of manufacturer testing and experience in the field can be requested, the actual applicability of laboratory-simulated testing of a component might have no relationship to the reliability of the system in actual clinical use. The clinical engineer can request that the manufacturer provide a complete list of spare parts recommended by the manufacturer. The actual service experience of organizations that use the same technology should be examined as well.

It is important to remember that some issues relating to maintenance and service can be transferred to others (e.g., the manufacturer or a shared service) by contract (see Chapters 7, 8, and 39). The bid could include, for example, provisions for the manufacturer to guarantee replacement parts availability, defined service response time and up time, the provision of “loaner” equipment, and training.

Laboratory Evaluation by Clinicians

Clinical evaluation of the product is an important part of the technology evaluation process. But clinicians should first evaluate the product in the testing laboratory before allowing it to be placed into the clinical environment. While there is an obvious safety aspect to laboratory evaluation, laboratory (i.e., simulated use) evaluation of the technology by clinicians offers an opportunity for clinicians to be trained in the use of the product, to be advised of limitations or differences noted by clinical engineering review, and to systematically examine the operation and human factors aspects of the product without the interference of a patient’s clinical need. Human factors with the interference of clinical need of a patient will be examined during the clinical evaluation. If simulated use identifies a shortcoming before use on a patient, the clinical engineer should not allow a product to progress to the clinical evaluation phase, where an accident might ensue (e.g., from a defeated alarm that staff thought was active).

Laboratory evaluation of the product by a clinician offers an opportunity for the collaboration and development of a relationship between clinical staff and clinical engineering staff. It can offer an opportunity to identify special training needs and requisite warnings that clinical staff who are responsible for the clinical evaluation should receive prior to initiation of the process. Current clinical practice on the existing product in use might not be recommended, or could even be hazardous, if used with the technology under evaluation. Staff need to know, prior to use of the product, that a change in practice not only can make the product more attractive to them, but also that it can enhance patient and/or staff safety. Including clinicians in the testing laboratory evaluation of the product can facilitate the inclusion of the clinical engineer in the clinical evaluation of the product. Such inclusion can have a number of benefits, including verification of laboratory findings, identification of new issues, and strengthening of the engineer/clinician relationship.

The results of the laboratory evaluation should be compiled, and a recommendation provided regarding whether and how to proceed further. The results might eliminate a product from further consideration. The recommendation might identify previously unidentified needs or costs. It should provide details of training and warnings that clinical staff who are responsible for clinical evaluation should receive prior to actual clinical use of the product. It might also identify additional questions to be answered prior to proceeding further.

Clinical Evaluation

Assuming that the product has not been eliminated by previous processes, it is important to assess the product in the area of expected use by representative expected users. Just as certain device design and facility limitations could have precluded the introduction of a

product into the facility for laboratory testing, so too, for various reasons, examining the product within the organization on a trial/evaluation basis might be impossible. In such instances, clinical evaluation could be limited to simulated clinical use, observation of clinical use by others, or use on, for example, volunteer, if performed within the confines of laws and regulations. In some cases, there might be special requirements for Institutional Review Board (IRB) approval of a protocol in order for the technology to be used on a patient or volunteer.

Clinical evaluation has many of the same features (e.g., confirming operations) as the laboratory and engineering evaluation of the product. Clinical evaluation extends laboratory and engineering evaluation by interjecting the clinical environment, including the patient, the user, and the facility. Clinical evaluation includes examining the performance, ease of use, human factors (see Chapter 83), and safety aspects of the product, but also should emphasize examining the differences between or among competing products. Clinical engineering can participate in the clinical evaluation process as an observer; although it is not paramount that the observer be a clinical engineer, it is paramount that an impartial observer participate. Often, a user does not realize exactly how they are using, or misusing, a product at the actual time in question. The user’s attention might be diverted to the patient, to another patient, to another product, or to another activity that is occurring but that does not include them. They might misinterpret user instructions and might believe they are using the product in accordance with manufacturer instructions. In fact, the device might contribute to such “user errors,” and this contribution is important to identify and note. They might misinterpret device presentations (e.g., visual warning or alarms), or correctly interpret them, but not be able to act accordingly without resetting the product.

An impartial, trained observer can watch how the products are being used and misused. Difficulties in use, product-related efforts that are particularly time consuming, and frequent need for replacement of accessories or options can be noted. Depending upon the specific issue and any safety ramifications, the observer can advise the clinical user of the situation or can withhold this information until it can be analyzed and evaluated. An argument can be made that the clinical engineer is well positioned to be an observer as he or she already will have received training on the device and will have operated it in the course of the laboratory and engineering evaluation. A strong argument can be made for the observer to be a member of the clinical staff that ultimately will make use of the product, because that professional eventually will need to be trained anyway and also has direct, hands-on, clinical experience. Regardless of who is chosen to observe, it is important to recognize that constant observation is neither recommended nor possible. Clinical use during the evaluation should be as natural as possible and should not compromise patient or staff safety. Observers who have tried to maintain constant vigilance for hours on end have been found to miss many important events.

Features of a clinical evaluation should encompass objective and subjective observations. Performance results (e.g., correct capture and identification of an arrhythmia that has occurred) can prove out objectively. Set up might be judged difficult by one evaluator, but easy by another. Such subjective assessments deserve further analysis if possible. It is important that the objective and subjective assessments of clinical staff be captured during the clinical evaluation. Objective assessments should be compared against, for example, actual performance specifications provided by the manufacturer and results of laboratory and engineering tests. Inconsistencies should be examined. Subjective assessments that might impact positively or negatively on final selection should be examined carefully to determine whether any objective tests can be performed to prove out or supplement the subjective results. One benefit of collecting subjective assessments is that staff misunderstanding can be addressed at that time and need not wait until the product has been purchased and placed into actual use.

The results of clinical evaluation should be compiled, and a recommendation provided, regarding whether and how to proceed. The results might eliminate a product from further consideration. They might identify two or more products that clinical staff would find acceptable for acquisition. They might identify training or staff issues or costs previously not identified. They might identify issues that remain to be clarified and, for example, require reexamination in the laboratory.

Vendor Evaluation

Certain aspects of vendor performance are part of other evaluations (e.g., parts availability in testing laboratory and engineering evaluation and past experience with a vendor’s product by clinicians in the clinical evaluation). But there are additional aspects to consider and to include in the complete process of technology evaluation. For example, how long has the vendor been in business, and how stable is it? Does the vendor have the manufacturing capacity and expertise to provide the product, training, and support? Does the vendor have an acceptable reputation within the industry, and has it behaved responsibly?

Final Evaluation and Selection

The process of final evaluation and selection should include all affected parties. A small group of experienced evaluators can cull through all of the information and results on the various evaluations in order to identify specific information that is important to the final decision, but inclusion of all parties and their interests in the final determination is desirable. The small group might seek additional information from others, (e.g., manufacturers), who will clarify remaining outstanding issues to the extent possible. They might seek to determine whether vendors are willing to provide additional financial or other incentives, or to provide additional training that testing has determined would be necessary for staff based on the results of the laboratory and engineering evaluation or the clinical evaluation. Where more than one product has successfully passed all of the internal evaluations with no clear preferences identified,

vendors should be advised that the organization is seeking ways in which to differentiate one opportunity from another, to facilitate a final decision. Vendors can offer concessions at this point. In the absence of concessions, the organization simply will make the best possible business decision.

Once all of the results and supplemental information have been compiled, the small group can develop a cost evaluation of the alternatives. The cost evaluation should capture a myriad of factors, including, but not limited to, the initial cost of the product purchase, the cost of accessories and options, freight cost, and installation cost (see Chapter 30). The cost of such things as spare parts and consumables should be identified. Costs related to staffing and training should be provided. Costs for operating expenses, such as electric or water cooling, should be provided if they are significant. If a life cycle cost analysis can be developed and depended upon for the purposes of comparison of one product to another, it should be provided as well. Armed with the results of the various evaluations, a final decision can be made. The decision and the rationale for the decision should be provided to all affected parties.

Conclusion

Technology evaluation is an important part of health care operations. Throughout the process, it requires the cooperation of many professionals, including the clinical engineer. It offers opportunities for the development of alliances and sharing of information for the benefit of patients and staff alike. If performed properly, it can provide a means for rational decision making that is acceptable to all stakeholders. It can help make the best use of human and financial resources in an industry where both are limited.

34

Technology procurement is an important element of the overall hospital technology management program (see Chapter 30). Procuring technology is a complex, detail focused process, although some members of the health care team and vendors believe that it is merely the act of writing the check. Unless careful attention to procedure and detail is maintained throughout the procurement process, significant and even catastrophic events may occur. For example, costly unbudgeted and unexpected “required options” might need to be acquired after equipment has been ordered, or unexpected installation changes could be required. In a worst case scenario, the technology might not be usable by the facility at all. It might be severely underutilized, thus having a dramatic financial impact, or use could result in injury to patient or staff.

It is imperative that an organized framework be developed to ensure that the actual procurement of technology results in the organization’s receiving the proper technology under the terms it believes appropriate. A flexible approach will be important to process the variety of technologies to be acquired. However, it is important to note the use of some basic, standardized tools; e.g., a request for quotation, which can be modified when need indicates, can result in better performance of the procurement process, thereby saving time and money. Procurement comprises the three following essential processes:

- Organizing the presentation of initial important requirement, once a decision has been made to consider a technology for acquisition
- Determining final specifications, options, terms, and conditions under which technology will be acquired
- Ensuring that technology and services expected are provided and/or insured before payment

The clinical engineer (CE) can utilize many of the skills learned in didactic training and through experience to assist the organization in methodically and safely procuring technology. It is imperative that clinical engineers remember at all times that they are team

members, and not solely responsible for either the technology procurement itself or the process. Technology procurement and the overall hospital technology management program require cooperation among and participation of professionals from a variety of disciplines. The clinical engineer can be a strong team member who can help to ensure that the actual clinical needs of the user are identified, addressed, and, to the extent possible, met. The clinical engineer can serve as the communication bridge among professionals of various disciplines, both inside and outside the organization. Important attributes that contribute to the effectiveness of the procurement process include the following:

- Attention to detail and process
- Quick study of technical and health care issues, both clinical and administrative
- Ability to create and manage relationships, inter- and intradepartmentally as well as externally
- Willingness to ask questions and request clarifications
- Excellent communication skills, both written and oral
- Ability to compile and manage information with an emphasis on determining compatibility.

Breakdowns in communication (e.g., between clinicians and vendor personnel) or lapses in process (e.g., specification of a term without a written commitment or agreement by the vendor in its response) can create significant and even insurmountable problems later in the technology acquisition process. The clinical engineer can facilitate procurement and the process by listening, interpreting, evaluating, and teaching. By asking the right questions, communicating the defined need, and monitoring whether expectations can be or are being met, the clinical engineer can contribute to the quality and scope of patient care as well as to the financial well-being of the organization.

The remaining portions of this chapter discuss several areas of specific importance to technology procurement and provide additional resources for the clinical engineer to access.

Technology Evaluation Process

Procurement follows evaluation. However, benefits accrue from the overlap of the two processes. The purpose of the technology evaluation process is to determine the value and need for existing, new, and alternative technologies that the organization must consider in order to provide clinical care to the patient population it serves. (see Chapters 32 and 33). As the technology evaluation team and those responsible for technology management assessment proceed through the process, the need to integrate information and actions with the technology procurement team becomes apparent.

Request for Information

The acquisition of initial information about requested or alternative technology precedes procurement. While the technology evaluation team could seek this information independently of the technology procurement team, there are several advantages to the procurement team's collaboration in such steps as the development of the initial request for information (RFI). The procurement and evaluation teams can begin the cooperative process of understanding the scope of the technology to be considered, the way the evaluation is to proceed, and the terms and conditions under which the technology will make its way into use. Specific advantages of close collaboration for evaluation and procurement include the following:

- Identification of basic specifications, options, terms, and conditions to be discussed in the early stages of the technology evaluation process
- The opportunity to advise vendors early in the process and in a consistent manner as to what the "ground rules" will be
- Vendors who are experienced in responding to standardized organizational requests and needs and who will appreciate the opportunity to respond in a thorough and cost-effective manner
- Reduction of duplication of efforts (tasks generally will be performed only once during the process)
- Errors and omissions that might arise from lack of (or miscommunication over) differences between the technology evaluation process and the technology procurement process can be minimized, controlled, and addressed expeditiously

The initial RFI is not intended to present all questions or even to acquire all important information. It is intended to seek adequate information from potential vendors of requested and alternative technologies, and to allow the technology evaluation team to compare information and prioritize some initial decisions about the technology(ies), clinical procedures, and vendors that should be considered further. A specific RFI can be prepared in cooperation with the technology evaluation team and distributed to potential vendors. The two teams should work together to detail the current specific clinical need identified within the organization and should request related information from potential vendors. Elements of the RFI should include the following:

- A comparison, by each vendor, of the vendor's and the competition's products, including past, current, and alternative products that are intended to (or otherwise might) meet the clinical need
- A discussion of other clinical specialties that might make use of the products
- A discussion and description, with references, of the clinical utility of the products, including all of the clinical procedures within the intended use of the product, those that are not currently included within the intended use but may be included at a later date, and those that are not included
- The current status of device listing with the United States Food and Drug Administration (FDA) and the manner in which the vendor received clearance to market the product
- The data that the vendor relied upon in its medical vendor submission to the FDA to assert that the product was safe and effective
- A description of the actual equipment, options, and accessories that will be necessary for the organization to acquire in order to perform the clinical procedures identified
- A description of the special considerations (e.g., for installation, utilities, service, or training) that the organization should consider during the technology evaluation process
- All user, service, and installation documentation (e.g., manuals)

Many other questions can be asked or requests for additional information made; the extent of these questions and requests will vary based on the complexity of the technology, the characteristics and timing structure of the technology evaluation process, and the status of the technology (e.g., experimental vs. widely accepted).

Information that is important to the procurement process might already have been gathered by the technology procurement team. Relevant information should be requested from this team as well. It is often worthwhile to consider proactively the need for information from all teams so that the process for acquiring information can be standardized.

Technical Specifications and Other Requirements

The technology procurement team should be identifying questions to be asked regarding specifications, as well as evaluating responses to the questions asked. Incomplete, unacceptably limited, or incomparable specifications often can be identified on initial inspection. Mistakes that might be made by comparing "apples to oranges" can be reduced. Important comparable differences can be identified and can result in either discontinuation of consideration of that vendor or a request for further clarification. Initial efforts can assist

in the development of a detailed Request for Quotation (RFQ) and can identify specific attributes that deserve closer inspection during laboratory and clinical evaluations.

Standardization

There is intrinsic value in standardizing technology to the extent practicable. Vendors, models, characteristics of similar (but not the same) equipment types, and service responsibilities can be standardized. The standardization can be within the products and services offered by a specific vendor, or include characteristics (e.g., communication buss) and services (e.g., guaranteed availability of loaner units across different vendors, service providers, and clinical areas of use). Members of the technology procurement team can do the following:

- Identify in which places and in what ways standardization is currently in place
- Evaluate whether existing or new standardization can apply to the technologies under consideration
- Identify the specific standardization of vendors, features, or services that should be addressed
- Compare offerings to what is available or currently in place within or throughout the organization

Standardization of specific elements should be placed in perspective with respect to other issues for the specific technology and decision under consideration; for example, the opportunity to rate the value of standardization against clinical utility.

Long-Term Relationship

The value of a long-term relationship with a vendor can be important to some decisions. If the vendor and the organization have experienced the procurement process together over prior acquisitions, and with great success, there is good reason to believe that additional successful mutual processes are achievable by the organization and the vendor. However, it is also important to be able to place a balanced perspective on long-term relationships with respect to all other aspects of the evaluation. For example, while an organization may have a successful long-term relationship with a vendor of patient monitoring equipment, other factors, such as the need to work with a different division, or the offering of first-generation equipment in another device type, could call into question the value of the long-term relationship for the specific technology under consideration. The clinical engineer can help the organization to assess the value of long-term relationships for the specific technology under consideration.

Service and Training

Service capabilities of the vendor and the clinical engineering department must be evaluated. The vendor's present and past ability to provide service and to train the hospital's clinical engineering department in servicing the equipment are important procurement considerations. Training needs of the user may encompass educational services as well as clinical user training. Aspects of safety training, such as those required with laser equipment, should also be considered.

The vendor's response to the RFI can provide a basic understanding of the service and training needs from the perspective of the vendor. The vendor is not the end user; the vendor might understate those needs or might not understand the expected environment of use within the organization. The vendor might describe the needs and its ability to provide support as it would like things to be, or as it perceives things to be, rather than as things actually are, from the user's perspective. CEs who are experienced in procurement can examine information submitted from all parties and can compare it to their experience with these and other vendors. An "apples to apples" comparison is more likely to result, and differences in service and training can be kept in the proper perspective among vendors and with other aspects of the evaluation.

Subjective Bias

Subjective bias is decision making or evaluation based on personal, poorly measurable, and unverifiable data or feelings that are improperly weighted against objective, unbiased data. Subjective bias can cloud the issues, impede the ability of a participant or group to make valid decisions, and result in costly mistakes. Participants in the technology evaluation and procurement processes might or might not recognize subjective bias on their part or on the part of other participants. As the relative power of the participant rises, subjective bias on their part and its potential negative effect on the process also rise. In an extreme case example, subjective bias on the part of the technology's hospital advocate who is already determined to select one vendor's product over all others can make it almost impossible to perform a valid assessment to acquire the best technology for the organization. If the technology from the "preferred because of an invalid bias" vendor happens to be the best technology for the organization, the outcome might be fruitful; if not, the organization risks acquiring the inappropriate technology, or the organization could lose the services of a talented clinician if decisions go against the clinician's bias.

The CE can help to identify and eliminate subjective bias simply by asking questions and requesting references in support of a position. An inability or unwillingness to answer questions or to provide references could be the result of subjective bias, although there might be other reasons as well, e.g., lack of competency in a new technology. If resources within the organization or the vendor are unable to answer questions or to provide references, the CE can seek an answer elsewhere, e.g., in the literature, from noted authorities, or from experienced users. Remembering that the technology evaluation and procurement processes are cooperative efforts, the CE can point out where there is bias or subjectivity and the importance of objectivity in decision making whenever possible. In some cases, it can be beneficial to utilize an unbiased, independent, expert consultant to facilitate consideration.

Procurement Financial Alternatives

It is often highly desirable to consider the financial impact and financial alternatives early in the technology evaluation and procurement processes. One reason to do so is to find alternatives for consideration of equipment that the organization simply cannot afford. Another reason is to avoid eliminating equipment that the organization could not afford under lump sum cash outlays, but that it might be able to afford under long-term, periodic payment structures that might be available.

There are three typical financial methods for acquiring the use of technology: Cash purchase, rental, or lease-purchase. Cash purchase typically requires the large, up-front expenditure of capital with periodic and ongoing maintenance, as well as service and upgrade costs. A portion of the value of the product can be written off each year until the product is fully depreciated. The purchaser typically owns the product as soon as it is accepted.

Rental usually requires a lesser initial capital expenditure, if any, and the organization does not own the product. There is no depreciation of the product because it is not owned, but there are periodic (e.g., annual or monthly) rental payments. The lease-purchase alternative is somewhat of a cross between purchase and rental; the terms of the lease and transfer of ownership at some point during or at the completion of the lease are negotiable and usually vary dramatically.

Reasons for choosing one alternative over another include cash flow considerations, source of funding, attractiveness of offers, expected product life cycle, expected frequency of upgrades required, and effects of each alternative on the overall financial position of the organization. One newer alternative, which is useful for especially costly technology (e.g., a proton beam therapy system), is development of a joint venture among, for example, a health care provider, a technical vendor, and a commercial partner. Up-front investments and responsibilities for various aspects of product use, upgrade, and support are split among participants, with the financial risk spread among them.

While scrutiny of the financial alternatives often rests with financial specialists within the organization, the CE can contribute to the validity of the data upon which these professionals will rely; for example, examining and evaluating the projected costs for maintenance, upgrades, and service within each alternative. That is, if the projected cost data and expected life expectancy of the product are incorrect, the financial assessment might be performed correctly, but the conclusion reached will be incorrect.

All of the above may be considered in the initial stages of technology evaluation through a conceptual needs analysis. The CE responsible for procurement can contribute to the decision of whether to move forward and with which vendors and technologies to do so.

Each recipient of the RFI should be advised of all decisions affecting that vendor. If a vendor has been eliminated from further consideration, the rationale for doing so can be conveyed to its representatives so that there is closure; the vendor can improve its sales efforts in the future if it has the ability and desire to do so. The vendors eliminated from the process might request the opportunity to resubmit or to supplement the submission of information. Permitting a vendor to resubmit should be a joint decision made by all team members.

Request for Quotation

Request for quotation (RFQ) is also known as request for bid, request for proposal, and request for tender. Assuming that the technology evaluation processes have been performed and that a decision to move forward has been made, a much more complete and detailed effort is necessary in order to identify specific equipment, services, and support that can be provided by each qualifying vendor. Extraneous applications and options can be eliminated from further consideration. Each vendor who is still under consideration can be provided with a much more complete idea of the nature and scope of the clinical need and technology interest. The RFQ is the organization's document; it is an opportunity for the organization to ask for whatever it wants. CEs who have been involved in prior procurements are well qualified to lead the effort to convey the interests and expectations of the organization to the vendor because they were involved in the initial RFI and some parts of the decision making process. As it is likely that much of the information eventually will be restated in the form of an acquisition contract, it is expedient for there to be consistency in the RFI, RFQ, and purchase contract processes. It should be understood that the RFQ, while an important step in the overall process, is not a legal transaction. It is an evolving process; i.e., it is subject to change as, for example, new information or opportunities are identified. Information that is gleaned from other subsequent tasks (e.g., laboratory and clinical evaluation) and discussions might require clarifications or changes in the RFQ.

Standard Template

It is unwise to attempt to reinvent the wheel every time a technology is evaluated. While the RFQ document should be flexible to evaluate varying technology, starting with a standard template and making necessary modifications to fit the specific technology have distinct advantages. There is a greater likelihood that the request will be complete and not miss a crucial item and that it will be compiled more rapidly and efficiently. Vendors can become experienced in what is expected of them and can "standardize" their responses if applicable, thereby reducing their costs. Those who are responsible for evaluating vendor responses can become experienced in responses and their implications. Often, a standardized comparison tool (e.g., a tabular program) can be more easily utilized if the RFQ is based on a standardized format. The process can expediently drive the comparison of "apples to apples." Often, the simplest way to begin developing a standardized request is to review and modify samples of RFQs that the organization has utilized successfully in the past.

One purpose of the RFQ is to convey the organization's interests and expectations to the vendor. In order to do so, the communication must be clear and understandable. The structure of the RFQ might include sections devoted to specific topics; e.g., introduction, equipment specifications, terms and conditions, installation, service, and training. Similarly, questions and requirements should be clear, concise, and easy for the vendor to understand.

There is a variety of templates available for consideration (ECRI, 1976; Mandell, 1986; ASHE, 1991), but most include some or all of the following elements:

- A narrative description of the organization's interest in the technology(ies), the contacts within the organization, and the period in which responses, presentations and procurement is expected to take place. It is not necessary to fully detail, for example, the clinical significance or efficacy of the device, as the vendor theoretically is expert in these areas or would not be providing the technology.
- Technical specifications that are particularly important to the intended clinical use of the technology and to the specific installation in the physical facility. Often, the RFQ provides the vendor with sufficient information on the basis of which to ask for and to gain more detail (from, for example, the clinical sponsor and the facilities engineer within the organization).
- Options that are mandatory and those that would or should be considered. The RFQ is an opportunity for the organization to ask for and to receive sufficient information on the basis of which to acquire and to use technology without the immediate need for additional options or costs subsequent to this acquisition, as well as to plan for clinical service changes and technology upgrades in the future.
- Consumables that must or should be acquired in order to use the technology. Cost is not the only issue related to consumables; availability also might be important if consumables are subject to back order, recall, or replacement.
- Documentation that will be provided. Typically, user and service manuals are mandatory. Descriptions of diagnostic software and specialty tools (e.g., test boards) are helpful.
- Installation requirements, including space, power, cooling, and weight. Typically there are two approaches to examining installation requirements. The organization can detail what it expects will be necessary, and it can require the vendor to advise the organization if this is correct and complete, or it can require the vendor to advise it as to what is necessary for a complete and correct installation. In either event, it is reasonable to require the vendor to perform a site analysis as part of the RFQ process so that unexpected and unnecessary problems (e.g., the floor's inability to carry the weight) do not occur at the time of actual installation.
- Costs over the expected lifetime of the technology (life cycle costs) for the various acquisition options (i.e., cash purchase, rent, lease, or joint venture) that are available through the vendor or that have been utilized by others acquiring the technology. Vendors are often aware of methods and sources of financing, as well as reimbursement;
- Training courses and materials that are available from the vendor, their agents, or others that are mandatory or desirable for clinical staff and service/repair professionals. Disclosure of cost, if any, should be required. In some cases (e.g., lasers), special physician training might be strongly recommended. In most cases, training of clinical staff may need to be performed in multiple locations throughout the 24-hour period, or the vendor will need to train the trainers. The need for service training should not be overlooked, even if vendor or third-party service is expected. At least one professional within the organization should have a working knowledge of the technology. Turnover in clinical and service staff occurs, and some mechanism to address training in the event of turnover is desirable.
- Identities of ten most similar clients, including contact names and information. It should be clear to the vendor that the organization intends to contact these clients to discuss their experience with the technology and the vendor, including use, service, and costs.
- Service options and resources available. The RFQ is an opportunity for the organization to learn everything that it can about what to expect in the way of service after procurement and installation are complete. Important service topics that can be examined include:
 - Service contracts and cost, as well as reduction in cost if first screening is performed by the organization
 - Guaranteed up time
 - Employer or independent dealer service
 - Location of service personnel
 - Number of personnel at the service location trained on the specific equipment, and location of backup service and contact options (e.g., hotline)
 - Availability and attributes of guaranteed response time
 - Parts availability, location, shipping schedule, and price list
 - Labor rate(s), standard hours, and travel time
 - Frequency and content of preventive maintenance provided
 - Availability of loaner equipment
 - Indemnification and liability insurance coverage
- Terms and conditions under which the technology will be acquired. This is the opportunity to do the following:
 - Require the vendor to install and acceptance test the technology
 - Identify how and when the vendor will receive payment
 - Specify penalties if the technology does not perform reliably or is not installed according to schedule
 - Detail how future versions of product hardware and software will be made available, performed, and charged
 - Require evidence of compliance with local, state, and federal codes and regulations

If the organization has unreasonable or unrealistic expectations or asks for information that is impossible to obtain, responses may be minimal without any need for them to be so. Hence, it is important for the organization to think about the aspects of the technology and vendor support or other offerings that are important to and desirable for the specific

procurement. The organization might even direct (in the RFQ) vendors to contact the organization to discuss any aspects of the RFQ that the vendors find confusing or objectionable. Although obtaining the best technology at the best price is always foremost on the minds of the organization, the organization and the vendor must work together effectively throughout the lifetime of the technology. If the RFP and subsequent interactions are fair, a solid working relationship can result.

Aspects of the RFQ and the successful vendor responses eventually will be reduced to a procurement contract. If the RFQ or responses are incomplete, the procurement contract might be expected to be incomplete. If, for example, a vendor does not respond and agree to provide service manuals, this issue probably will arise later, perhaps unexpectedly.

Vendor Presentation

Some organizations find that a formal presentation by the vendor is beneficial. Vendor presentations are opportunities for learning, both for the professionals within the organization and for the vendor. Clinical professionals can learn new information about the attributes of the technology and gain an understanding of the extent of costs that will be assumed and the support that will be required. Vendors can learn more about the relative importance that the organization places on cost versus performance, or on some other attribute of the procurement.

In some instances, it might be possible to eliminate a vendor based on preliminary analysis or on the vendor's response and presentation. To do so it is clearly indicated and supported objectively. It would be unwise to eliminate a vendor where a more complete analysis of the vendor's response or subsequent questioning might result in that vendor as the best, not the worst, alternative. Rebidding should be discouraged as it costs both the organization and the vendor time and money.

Response Analysis

Once the vendors have responded to the RFQ, the responses must be compiled and compared. If the RFQ is standardized, the responses are complete, and a standardized analysis tool can be utilized, then the process may be fairly straightforward. Many organizations find a tabular format easy to use. One major responsibility of those who are responsible for the analysis is to be sure to compare "apples to apples." If a like comparison is not possible, contact with the vendors should be made in order to acquire information that is more comparable.

The analysis should focus on information that is important to comparing procurement options. While it is important, for example, to ensure that all of the vendors' technology meets the basic required technical specifications, once this determination has been made, the information can be eliminated from the comparison table, and just a note need be included that all vendors meet the specifications. It is important to identify differences among vendor responses (e.g., in price); however, it is just as important to remember that a vendor's response could be subject to change if it becomes a potential reason for eliminating that vendor and they are advised of that potential. Providing vendors with the opportunity to provide the rationale for questionable items may identify a miscommunication and subsequent clarification.

Comparison and tabular presentation of differences in responses with regard to price, payments, and terms are typical. However, it is also important to capture crucial information such as omissions and errors in the responses, a vendor's special attributes, and special technology attributes. Omissions and errors should be discussed with the vendor, to determine whether additional information can be acquired from the vendor. Special attributes of the vendor often relate to the vendor's history in the industry and their reputation with customers. For example, if the vendor has a history of unsatisfied customers, and the dissatisfaction is based on objective information, this is important information to include in the analysis. Still, it is important to remember that some causes of dissatisfaction (e.g., service response time) can be addressed, to some extent, by terms and conditions within the purchase contract. Special attributes of the technology often relate to such issues as a small installed base, a brand new product line, or an older system, compatibility, or special design.

Ultimately, the analysis may include a formal tabular comparison, additional objective findings, subjective findings, and points raised in the analysis to develop recommendations for proceeding. The results of the analysis can range from discontinuation of the procurement and technology evaluation process, to elimination of some of the responding vendors, to consideration of all responding vendors in subsequent steps. Many organizations find it helpful to stress within the analysis that the results, findings, terms, and conditions are subject to change prior to procurement, either because of changes in need or as the result of negotiations.

Laboratory and Clinical Evaluation

Once the analysis is completed, decisions related to laboratory and clinical evaluation can be finalized. Which vendors to consider, what technology and options to request for evaluation, and the timetable to be utilized to perform the evaluations will have to be decided (see Chapter 33). It is advisable to keep the CE who is responsible for procurement in the information loop during the evaluation period. Decisions made and information learned may directly affect the procurement process subsequent to the evaluation. Once these important evaluation aspects of the process are completed, tasks that are related to the procurement process can be expected to accelerate.

Revision of Technical Specifications and Other Requirements

Revision of specifications is often necessary from what is learned during the evaluation process. Revision may include identification of the preferred vendor(s), specific options, accessories, features, training, or service. It is important that procurement professionals work closely with the evaluation team to identify any desirable changes or additions that have become apparent during the evaluation process. It is common for questions to remain and to require addressing by the vendor(s).

Unless there is overwhelming reason to do so, it is not typically wise to reduce the field of vendors for final procurement to one vendor. Doing so can minimize the organization's ability to negotiate such items as cost and terms. In addition, it is reasonable and ethical to explain to each vendor the identified differences and shortcomings of the response and equipment, along with an offer to each vendor to explain any rationale for the difference or the ability to compete. Questions about cost, performance, and options are ethically appropriate for the vendor and organization alike.

It is also important to capture and communicate to team members and decision makers requirements for installation, training, and service of the vendors who remain in competition. In some instances, a recompilation and re-analysis of information might be necessary. Occasionally, a rebid of the entire procurement may be necessary. It is important for procurement professionals to analyze the information received from the initial RFQ process, the information received from the results of the evaluation processes, and any clarifying information received by the vendors to determine whether sufficient information exists on which to finalize the award. If additional information is needed, or if insufficient information exists, the procurement professional should take the time to rectify the situation or to ensure that the proper professionals within the organization are aware of the issues.

Assuming that adequate information on which to base the award has been collected, and that the original RFQ was complete, the process of revision can be expedited. If the revision document is complete, the process of moving to award with a procurement contract can be expedited.

Selection and Payment

RFQs, evaluations, and revisions have been completed. Thus, the procurement team moves to "award" and the job of the CE in the procurement process is done, right? Wrong! It is important to ensure that the technology, options, services, and other "promised items" are delivered. The first step in assuring that promised items are delivered is to provide an award document that clearly spells out what these promised items are.

Contract

A procurement or purchase or lease contract, by whatever name, is desirable. The language of the document should be tailored to the specific aspects of the technology and should have undergone prior review by legal counsel. If standardized, transferring information into the award procurement contract from the preceding procurement documents can be expedited.

Standard features of a procurement contract include a detailed description of the technology, options, accessories, documentation, and software to be provided by the vendor. The contract usually also includes the specific conditions of sale, such as the following:

- Installation requirements, responsibilities, and timetable
- Acceptance testing requirements, responsibility, and timetable
- Warranty details, spare parts availability, and service requirements
- Clinical, service, and other training to be provided, assignment of cost for same, and schedule for doing so

Of course, the contract will incur costs. Often, it is wise to identify not only the costs for which the organization will take responsibility, but also the costs for which the vendor or others involved in the procurement will take responsibility. Doing so can avoid subsequent questions of payment responsibility and the unexpected need to assign more dollars than expected. The contract also typically identifies payment schedules (e.g., 10% withheld until final acceptance testing complete), ability to assign the contract, grounds for and methods of cancellation, and price protection.

The CE who is responsible for the procurement can protect the organization by taking the time to identify all of the technology features, options, accessories, services, and other acquisition issues that are important to the organization, and for ensuring that those items are contained within the procurement contract. Sufficient detail as to each, in order to identify what is required, to ensure that each is delivered, and to specify penalties can minimize misunderstandings and future problems.

Sometimes overlooked in the process is the need to advise vendors that are not receiving the award that an award has been made. The vendors typically have devoted time and resources to their response, and each vendor deserves to be advised. The organization should document the reasons for the selection. Depending on the situation, there may be merit in advising the vendor(s) of the reasons. Vendors might be able to improve their marketing and presentation response in the future and might decide to improve their technology and offerings. In some cases, the organization might subsequently need to consider acquisition of technology from a vendor that it did not select for a particular procurement.

Incoming Inspection and Acceptance

Once the award has been made, the process of monitoring and verifying the installation and delivery of the technology will begin. While this is an important aspect of the procurement process, it is discussed in detail elsewhere in this handbook (see Chapter 6 and 122). In short, acceptance testing, monitoring installation, and verifying delivery of specified items ensures the following:

- The technology performs its intended function
- Initial (baseline) performance characteristics are measured and recorded
- Incoming inspection and acceptance testing is performed and met
- The remaining terms and conditions of sale are met

Payment

Assuming that payment conditions have been detailed in the procurement contract, the CE need advise the appropriate personnel in the organization only when milestones are achieved or in the event that problems have arisen. In the event that a problem arises, the CE who is responsible for procurement may assume primary responsibility for determining the way that problems are to be resolved, and he may negotiate costs based on the effect of the

problem. While CEs may not have the final authority on these aspects of the process, they can and should contribute significantly, identifying the ramifications of problems and the adequacy of proposed resolutions.

Monitoring

The procurement process is not complete upon final payment. Often, monitoring of medical staff satisfaction, equipment performance (e.g., uptime), provision of subsequent services (e.g., preventive maintenance and quality control), and calculation of life cycle costs must be performed. Along with addressing direct promises and needs, such monitoring can contribute to the organization's knowledge base and expertise for future acquisitions. In some instances, it can help to contribute to meeting accreditation; (e.g., JCAHO) and to satisfying regulatory requirements (e.g., CLIA).

Conclusion

The clinical engineer has a solid background on which to assume primary responsibility for the procurement process. It is important that the clinical engineer recognize the clinical

and financial experts within the organization as critical participants in the process. Careful attention to detail throughout the process with the intent to capture important information and to advise the organization's and vendor's professionals of this information helps to improve the process. Developing a request for proposal and following through to the procurement contract, payment, installation, and use of the technology is truly a lesson in communication. Expediting communication through the assurance that adequate information is passed along to all parties and that responsibilities are clear can make the process a win-win one for all participants.

Equipment Control and Asset Management

Matthew F. Baretich

President, Baretich Engineering, Inc.
Fort Collins, CO

The number of critical medical devices used in a hospital may range from something on the order of 1000 devices for smaller community hospitals to well over 10,000 devices for large, academic medical centers. In this context, "critical" refers to a medical device that requires individual tracking and management to insure safe, effective, and economical use.

The importance of this task calls for a carefully designed equipment control and asset-management program. In practice, the magnitude of the task effectively requires the use of a computerized maintenance management system (CMMS). A well-crafted, CMMS-based equipment control and asset management program (see Chapter 36) represents the fundamental information resource that supports many of the medical technology management activities described in this handbook.

This chapter describes basic principles that can be used to determine the medical devices that should be included in an equipment control and asset management program. Inappropriate exclusion of a device can compromise its safety and effectiveness; inappropriate inclusion of a device is a waste of maintenance resources. Thus, well-designed inclusion criteria are necessary for optimization of safety, effectiveness, and economy.

Acknowledgment

Research for this article was supported by Hospital Shared Services of Denver, Colorado.

Background

The Joint Commission on Accreditation of Health Care Organizations (JCAHO) requires hospitals to "establish and maintain an equipment management program to promote the safe and effective use of equipment" (JCAHO 2002). Efficient and economical compliance with this standard is a challenge facing most hospitals in the United States.

A fundamental aspect of medical equipment management is a program of scheduled maintenance. As reflected in JCAHO Standard EC.1.6, the essential components of a scheduled maintenance program are the following:

- **Inventory.** Definition of medical devices to be included in the program
- **Procedures.** Definition of maintenance activities to be performed on devices in the program inventory

- **Scheduling.** Definition of when maintenance activities are to be performed on devices in the program inventory
- **Monitoring.** Continuous measurement and periodic review of program performance

Prior to 1989, JCAHO standards required hospitals to include all medical devices in the equipment management program inventory. Since that time, JCAHO standards have allowed hospitals the flexibility to exclude certain devices so that maintenance resources can be focused where most needed. Current JCAHO standards allow hospitals to establish "risk criteria for identifying, evaluating, and taking inventory of equipment to be included in the management program." These criteria must address "equipment function (diagnosis, care, treatment, and monitoring), physical risks associated with use, and equipment incident history."

Thus, the concept of a "risk-based inventory" was established. In pursuit of operational cost-effectiveness and compliance with JCAHO standards, most United States hospitals have implemented some form of risk-based inventory system.

Literature Review

Since 1989, there have been numerous publications in the clinical engineering literature proposing risk-based inventory systems for equipment management programs.

Of particular influence have been recommendations published by recognized professional organizations, e.g., ECRI, the Association for the Advancement of Medical Instrumentation (AAMI), and the American Society of Hospital Engineering (ASHE); highly regarded journals (e.g., *Journal of Clinical Engineering* and *Biomedical Instrumentation & Technology*); and JCAHO itself.

In the literature and in practice, two broad approaches to designing a risk-based inventory for medical equipment are followed. The first approach is to identify "critical" or "high-risk" medical devices and to use this information as the primary factor in deciding which medical devices to include in the equipment management program. An important example of this approach is the *Health Devices Inspection and Preventive Maintenance System* that is published by ECRI (1995). This system divides medical devices into "high-risk," "medium-risk," and "low-risk" categories on the basis of "risks of injury caused by device failure or user error." ECRI suggests that devices in the first two categories are

typically included in an equipment management program. However, ECRI also emphasizes that “although risk level is an important indicator, it alone does not define a device’s support requirements”

Another example of this approach is the medical device classification system, which is run by the United States Food and Drug Administration (FDA) (www.fda.gov/cdrh/prodcode.html). (See Chapter 126.) The primary purpose of this classification system is to establish the level of regulatory control required for the marketing of medical devices. Class I devices require the least regulatory control, while Class II and Class III devices require increasing levels of regulation. The FDA notes that “the risk the device poses to the patient and/or the user is a major factor in the class it is assigned.”

The FDA does not represent its device classification system as being applicable to designing a risk-based inventory system for medical equipment maintenance. However, some publications do refer to the FDA classifications in this regard. A prominent example is the consensus standard, Recommended Practice for a Medical Equipment Management Program (American National Standard ANSI/AAMI EQ56:1999), which states that “most health care organizations will want to include devices falling into Class II or Class III within their equipment inventory list” (AAMI 1999). (See Chapter 122.)

The second basic approach is to use a numerical algorithm to determine the medical devices that should be included in an equipment management program (Fennigkoh and Smith, 1989).

The Fennigkoh and Smith algorithm scores medical devices on three factors:

1. Function (2-10)
2. Risk (1-5)
3. Required maintenance (1-5)

The sum of these scores yields an “equipment management” (EM) number. Devices for which $EM \geq 12$ are included in the equipment management program. The Fennigkoh and Smith algorithm and its many derivatives have been incorporated into commercial CMMS software, implemented as online calculators, (e.g., www.currentpath.com) and applied by numerous health care organizations. American Society for Health care Engineering (ASHE 1996) developed one of the most widely distributed derivatives, which includes additional factors and a different method of calculation. Wang and Levenson (2000) provided a detailed review of algorithm-based systems. These authors also recommended a modification of the Fennigkoh and Smith algorithm to incorporate a “mission criticality” score reflecting the importance of a medical device to the mission of a health care organization.

Although the Fennigkoh and Smith-based algorithms were valuable responses to the 1989 changes in JCAHO standards, there now is reason to question their conceptual underpinnings. For example, although these algorithms generally include a “maintenance requirement” factor, it is possible for a medical device with recognized maintenance requirements to be excluded from the equipment management program if it has low enough “scores” on other factors in the algorithm (a consequence of the additive nature of these algorithms). Also, some Fennigkoh and Smith derivatives ASHE (1996) use the result of a single algorithm to determine both inclusion in the program and frequency of maintenance, two fundamentally distinct concepts that should be based on different considerations.

Ridgway has proposed a different conceptual approach (2001) in which medical devices to be included in a “monitored maintenance program” are those that are “critical devices in the sense that they have a significant potential to cause injury if they do not function properly” and that are “maintenance sensitive in the sense that they have a significant potential to function improperly if they are not provided with an adequate level of PM.” Noncritical devices are excluded, as are devices for which there is no evidence of benefit from “planned maintenance.”

Principles

Health care organizations vary widely in their implementations of JCAHO-compliant equipment management programs. They have adopted a variety of approaches to designing risk-based inventory systems, developing maintenance procedures and schedules, and measuring performance. A significant variation in terminology exists with regard to scheduled maintenance programs. Recognizing the wide range of practice in the profession, this chapter offers general principles that health care organizations can use as guidelines in developing their equipment control and asset management programs. These guidelines are based on best practices described in the literature and observed in practice. They should be adapted to the policies, procedures, and terminology of each unique health care organization.

What are the objectives of a scheduled maintenance program?

Using ECRI (1996) terminology, the following are the key objectives of a scheduled maintenance program for medical equipment:

- To reduce the risk of injury or adverse impact on patient care
- To decrease equipment life cycle costs
- To comply with codes, standards, and regulations

What Categories of Procedures Are Part of Scheduled Maintenance?

Adapting ECRI’s (1996) and Ridgway’s (2001) terminology, scheduled maintenance activities may be categorized as follows:

- Procedures to reduce the likelihood of premature failure (true preventive maintenance)
- Procedures to determine the performance of the device relative to its specifications
- Procedures to determine the safety of the device relative to applicable standards

What devices should be included in a scheduled maintenance program?

A medical device should be included in a scheduled maintenance program if any of the program objectives can be achieved by any of the maintenance activities described above. Here are some examples of this principle:

- If a device can fail in a manner that may cause patient injury, and if the likelihood of that failure can be reduced by one or more categories of scheduled maintenance activities, the device should be included in the scheduled maintenance program.
- If the life cycle cost of a device can be reduced by one or more categories of scheduled maintenance activities, the device should be included in the scheduled maintenance program.
- If applicable standards require a device to receive periodic inspection (falling into one or more categories of scheduled maintenance activities), it should be included in the scheduled maintenance program.

What devices present a risk of injury or adverse impact on patient care?

Two widely recognized resources regarding the “risk level” of medical devices are ECRI (1995) and FDA (www.fda.gov/cdrh/prodcode.html). These resources provide an initial assessment of “risk level” that can be adjusted on the basis of experience within a particular health care organization.

What devices are “maintenance sensitive”?

Following the definition in Ridgway (2001), a device is “maintenance sensitive” if it can be expected to function improperly in the absence of appropriate scheduled maintenance. Ridgway provides conceptual guidelines for this concept. Device-specific information can be gathered from manufacturers’ recommendations; guidelines published by recognized organizations (e.g., ECRI, AAMI, and ASHE); experience within a particular health care organization; and professional knowledge regarding medical device design and operation.

Summary

These broad principles may be used to determine the medical devices that should be included in an equipment control and asset management program. After this determination has been made, these devices can be entered into a computerized maintenance management system. The CMMS can be used as a basis for planning and documenting scheduled and unscheduled maintenance activities. The CMMS also can be used for performance monitoring of the equipment control and asset management program. The result is a management tool for achieving safety, effectiveness, and economy in equipment maintenance.

Computerized Maintenance Management Systems

Ted Cohen

Manager, Clinical Engineering Department, Sacramento Medical Center
University of California,
Sacramento, CA

Nicholas Cram

Texas A & M University
College Station, TX

How do clinical engineers (CEs) ensure that the medical systems installed in their customers' health care organizations are functioning optimally? What do they do when those medical systems malfunction? What is the quickest route to restoring performance of the medical system to the customer's satisfaction, and at what cost? How do they help to determine when to replace a major system? How do they interact with the health care providers and all other customers in a modern, complex, health care organization such as accrediting organizations, the FDA, device manufacturers, risk managers, and attorneys? Most use some type of computerized record keeping system to help them to manage their business.

Computerized maintenance management systems (CMMSs) have evolved into a useful tool for providing technology support. Whether supporting a three-technician shop or an international service organization, almost all medical equipment support organizations are using some type of CMMS in their operations. A CMMS can be classified broadly as internally developed (typically using commercial off-the-shelf (COTS) personal computer hardware and database software); commercial CMMS applications; or the newest approach—application service providers (essentially a web-based software rental service). This chapter reports on the current status of computerized maintenance management systems (CMMS) in use in hospitals and health care systems today and some of the future technologies that the future leaning providers of medical technology support services are starting to use.

Computerized maintenance management systems can provide the technology management staff with a wealth of information to help manage many technology support-related functions. Examples include the following:

1. Quantitative equipment reliability assessments can be made, based on failure rate, down time, and repair and maintenance costs. These assessments can be used to determine equipment that should be replaced and that should assist in the subsequent vendor selection for the new product being purchased.
2. User/operator training needs can be identified based on trends in use error problems (e.g., problem not repeatable, incorrect settings, liquid spills, and physical damage).
3. Scheduled maintenance can be prioritized based on the risk to the patient of an equipment failure and the maintenance needs of the device. CMMSs can be used to balance and manage this often large workload better.
4. Scheduled maintenance program effectiveness can be measured by the rate of problems identified (yield), parts replaced, equipment not found/not available as compared to the total number of inspections performed by risk priority, and again, used to manage this often very large workload.
5. Workorder systems can be used to prioritize repair requests and better manage down time of critical systems.

This chapter addresses the following areas: Medical equipment management fundamentals, the CMMS core, CMMS modules, data integrity, reports, utilities, network and multiuser issues, and new technologies.

Medical Equipment Management Fundamentals

Technology plays a major role in the delivery of today's health care. Keeping the medical devices that help to provide that care in good working order is the role of equipment service management. In 1993, U.S. hospitals spent over \$3 billion (ECRI, 1993) to service their medical equipment. Appropriate equipment service, whether performed by hospital personnel, equipment manufacturers, or contracted third-party organizations, is essential to modern, high-quality, cost-effective health care.

Modern health care organizations must carefully manage all equipment service independent of the service provider, who may be an employee, a contractor, a manufacturer representative or an employee of another organization affiliated with the health care insti-

tution, e.g., group purchasing organization (GPO). Comprehensive equipment service management includes all medical technology and all service providers. In many cases there will be multiple service providers that may include multiple in-house groups (e.g., clinical engineering, radiological engineering, multiple manufacturers, and multiple independent contractors). In other cases, there may be one in-house or contracted organization coordinating all of the service regardless of who is the actual service provider for a specific device or repair.

In addition to the actual equipment maintenance and repair, the technology management team should participate in all phases of a device's lifespan, including capital budget planning, equipment needs analysis, specification and request for proposal/bid authoring, vendor selection, service provider evaluation and monitoring, service contract evaluation and monitoring, installation planning, installation, acceptance, user education, product recalls and alerts, incident and accident investigation, replacement analysis, de-installation, and salvage. (See Chapter 30.) Overall program cost management is another key function.

Regardless of the service provider model, service is coordinated by a service manager who may be on-site in larger organizations or who may be shared among several sites for smaller hospitals. The service manager could be an employee of the health care organization, a contracted employee, or an employee of a vendor. There are many different cost models for the payment of medical device service, and it is the responsibility of the service manager to coordinate such service in an efficacious and cost-effective manner within the defined description of the manager's job as directed by senior leadership.

Equipment Management Implementation

The first, and one of the most critical, steps in implementing an equipment management system (computerized or noncomputerized) is to complete an accurate inventory of all equipment that will be under the equipment management program, including devices that will be serviced by other organizations but whose service needs to be tracked. Each device that needs to be tracked must have an equipment control number assigned to it and labeled on the device. In some hospitals, the hospital asset number or property number already assigned to the device may be used as an equipment control number. If the asset tracking system is incomplete or if the format of the asset number is not compatible with the equipment management system, then an independent equipment control numbering system might need to be developed. Without an effective inventory system, it is impossible to track maintenance and repairs, alerts and recalls, and most of the other equipment-management functions accurately.

The inventory must be kept accurate and must be frequently updated as new equipment is added to the hospital's inventory and old equipment is removed. This task involves policies and procedures that include the equipment management function as a critical part of the hospital's new equipment-receiving function and equipment-removal and -salvage operations.

Important parameters to be tracked in association with each device in the inventory are the model, serial number, warranty expiration date, risk of the device, type of device, ownership information, maintenance scheduling information, and purchase information. A sample list of data fields and their definitions is included Cohen (1994).

JCAHO

The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) (JCAHO, 2000) has considerable impact on the equipment management program. The following is a discussion of some of the equipment management-related JCAHO requirements.

Standard EC.1.6: The hospital plans for managing medical equipment.

The intent statement for EC.1.6 starts as follows: "The hospital identifies how it will establish and maintain an equipment management program to promote the safe and effective use of equipment"

The equipment management program is documented via the equipment management plan. This plan includes processes for selecting and acquiring equipment and for establishing criteria for identifying, evaluating, and taking inventory of equipment to be included in the management program before the equipment is put into clinical use.

A hospital has the option of including all patient care equipment in its program or developing written-assessment criteria and applying those criteria on a device-type by device-type basis to determine whether a device is to be included in the equipment-management program. All patient care equipment must be assessed, independent of acquisition source, including rentals, leases, donations, and physician-owned equipment. The written assessment criteria should include the following:

- Equipment function (e.g., Does the device provide life support or a resuscitation function?)
- Physical and clinical risks to the patient: What is the likelihood that the device will fail in such a way as to cause serious physical injury? How is the device used, and how is data from the device used? What would happen if the device displayed or reported clinical data erroneously?
- Maintenance requirements: Does the device require periodic parts replacement, lubrication, recalibration, or other routine maintenance in order to perform properly and safely? What maintenance is performed by the user, and how frequently is it performed? What additional maintenance must be performed by the service provider?
- Incident history: Does the device have a history of incident reports or other serious reported problems?

Many different schemes have been developed to determine the risk associated with a given device or type of device. The simplest provide a three-level categorization (high-risk, moderate-risk, and low-risk) for each device included in the equipment management program. Some systems also include the ability to define and identify critical systems. Moreover, low-risk devices with no maintenance requirements might not need to be included in the plan as they are dependent on local codes, standards, and policies.

In addition to the JCAHO, various other state, local, building code-related authorities (e.g., National Fire Protection Association [NFPA]), and professional organizations (e.g., College of American Pathologists [CAP] and the American Blood Bank Association [ABBA]), have accreditation requirements and licensing laws, regulations, and standards that vary by locale and type of institution.

Data Collection

The primary incoming data to the equipment management program are repair information, scheduled maintenance workorders, new equipment receipts, product recalls and alerts, and incidents and other hazard information. This large amount of information needs to be collected in a user-friendly yet controlled and organized manner. Nonautomated means of collecting these data have been by way of paper forms for work orders (both scheduled and unscheduled), telephone requests, and incoming equipment documents (internal documents or vendor packing slips).

Equipment data management schemes typically are based on each device's unique equipment control number as assigned by the health care institution or its contracted service-management organization. A file is established for each device and activity repair and maintenance activities logged in that file. This file should include all maintenance and repair activities performed on the device, regardless of the service provider.

With nonautomated equipment management systems, it is difficult to implement statistical analysis of the data including cost center accounting information, device-type problem analysis, and reporting and other statistical analysis for trending and reporting problems. When the inventory includes large numbers of devices and therefore large numbers of scheduled and unscheduled workorders, statistical analysis by noncomputerized methods become overly cumbersome. Many large hospitals have more than 10,000 devices and complete more than 20,000 work orders in one year. Statistical analysis of these data must be performed in order to reveal useful trends of problems categorized by department, by equipment model and by type of equipment. These trends then become information that can be used to identify equipment requiring replacement, user-training requirements by department, and user-training requirements by type of device or model. Obviously, management of this large amount of data is one of the reasons that computers are used for modern equipment management programs.

Clinical engineers and hospital administrators are recognizing the cost and technical advantages of centralization in equipment management and maintenance services, as can be seen by the increasing responsibilities that many clinical engineering departments and contractors are receiving. These include increased maintenance and repair responsibilities for clinical equipment in radiology and the clinical laboratory and for nonclinical equipment involving information technology, telecommunications, and material-moving robots. In addition, as large hospitals purchase or jointly manage neighboring smaller hospitals, clinics, free-standing surgery centers, and other healthcare-related facilities, the repair and maintenance of medical equipment in those facilities is frequently coming under the responsibility of the parent organization's clinical engineering department. As growth in responsibility, technical complexity, and volume continues, it becomes clear that computerized databases are required in order to manage the large amount of data and to convert those data into useful management information.

The Computerized Maintenance Management System Core

The core of an equipment management system comprises equipment inventory, repair and maintenance history, and work order control. The equipment inventory is an automated file of all of the equipment that has been included in the CMMS. The repair and

maintenance history is a record of each repair and maintenance event, independent of who initiated the event and who provided the service. Work order control is used to dispatch and to prioritize requested work, to schedule periodic inspections and preventive maintenance (PM), and to track the status of pending scheduled and unscheduled workorders.

Equipment Inventory

In the typical CMMS, when new equipment is received, a biomedical equipment technician (BMET) ensures that the order is complete; inspects and tests the device in accordance with the service manual that is provided as part of the order; and, based on the type of device, the organization's inclusion criteria, and the policies of the clinical engineering organization, determines whether the device needs to be included in the equipment management program. If it does, the BMET then enters the new item onto the database (or completes a form so that a data entry clerk can enter it) as well as completing an incoming inspection work order.

Device descriptions and other fields should be made as consistent as possible by using the ECRI device nomenclature (ECRI, 1994) and relational database techniques where, for example, each unique model entry has one entry that is referenced by all equipment entries of that model. Each model and device type also can include various defaulted fields (e.g., scheduled maintenance information such as inspection frequency and maintenance procedure reference). A similar construct may be used for the owning department (cost center) with defaults for minimum scheduled maintenance frequency and location. This building block approach, with references to standard tables (e.g., departments and type descriptions) and built-in default values, allows equipment records to be built quickly with maximum data integrity and flexibility.

Cohen (1994) lists fields, and their definitions, that typically are stored as part of the equipment inventory.

For those new devices whose model and/or type description are not yet in the CMMS, the equipment type record must be built first, and then the model record, before the new equipment record can be generated.

The Integrated History Record

The second part of the core of the CMMS is the integrated history record. Whereas equipment records are fairly standardized across most CMMSs, the maintenance and repair records are not standardized, nor is there a consensus on the data that are necessary to collect. There is a large variation among CMMS regarding the particular data that are collected, how they are collected, and how they are used.

The integrated history record concept provides a service provider with independent date-and-time-tagged repair and maintenance history associated with each service event.

The fields for the integrated history record are listed in Cohen (1994).

The typical history record contains the following information:

- Original problem or request: Text of original problem request
- Work order type: Category of work (e.g., scheduled maintenance, repair, incoming inspection, project, and recall/alert)
- Open date and time: Origination date and time
- One or more tasks where each contains the following information:
 - Start and end dates, and times for each task
 - Status of the work order at the end of the task (e.g., complete or awaiting parts) and referred to a vendor
- Service provider, technician, engineer identification: Who performed the task (e.g., vendor, CE, or BMET)
- Labor hours for the task, including travel and overtime
- Parts and materials cost
- Reference to a parts purchase order, vendor repair order, or stock parts sales order
- Down time: Especially important for high-cost medical equipment (e.g., imaging equipment) where down time significantly adversely affects patient throughput and thus revenue

Associated with each task is a list of zero or more specific actions taken as part of the task. There is no consensus in the clinical engineering community as to whether these additional important data should be encoded or free text. Certain special fields that cause other actions to occur must be encoded (e.g., codes that indicate the status of the work order and codes that are used to update the scheduled due dates). These include electrical safety pass, inspection complete, and PM complete. Other fields can be either free text or encoded. Free text generally provides more comprehensible information; encoded data are easier to analyze statistically.

Work Order Subsystem

The work order subsystem of the typical CMMS consists of the following modules: An unscheduled (requested) work order manager and technician dispatcher and an inspection and PM scheduler. Some systems also include an inspection preventive maintenance procedure library.

The unscheduled work order manager documents incoming requests for repair services and keeps track of the work order until completion. Typical tracked information includes request for name and phone number, equipment identification, equipment problem and/or service requested, equipment location, type of work order (i.e., repair, new inspection, or product recall/alert), and priority of the work order (i.e., how soon the customer needs the work completed). See Cohen (1994) for a list of fields and their definitions.

The maintenance scheduler is used to initiate and to manage scheduled inspections, scheduled parts replacement, and scheduled preventive maintenance work orders.

Scheduled inspections are defined as periodic inspections that verify that the product meets manufacturer's specifications by using externally calibrated sources and measuring devices. Generally, scheduled inspections will be completed on site and will not require removing equipment covers. Periodic parts replacements are replacements of specific, predetermined parts at predetermined intervals (e.g., replace nickel-cadmium defibrillator batteries every two years).

PM are actions that are necessary or desirable in order to extend the operational intervals between failure, to extend the life of the equipment, or to detect and correct problems that are not apparent to the user. PM could include scheduled parts replacement and inspection activities, but PM is generally more invasive, typically requiring the equipment to be brought to a shop location and requiring access to the internal portions of the equipment. For example, lubricating the moving parts of an electric bed would be preventive maintenance.

In the typical CMMS, each device has associated with it scheduled inspection data that include the following for each type of scheduled inspection: Provider responsibility (i.e., the service provider that is responsible for completing the inspection and PM), an interval (e.g., 12 months), fixed or floating flag, a synchronization date for fixed scheduling, the most recent completion date, and the next due date.

The next due date is calculated based on either a fixed or a floating basis. A fixed schedule results in the work being scheduled at the same time each year, based on the interval, and a synchronization date, regardless of when the last inspection was completed. A floating schedule results in a new due date determined by the inspection interval and the date the last inspection was completed. Upon request or at fixed times (e.g., weekly or monthly), the inspection scheduler initiates and prints, based on the parameters listed above, a summary of detailed work orders that are the scheduled work for the following period.

The inspection and preventive maintenance procedure library consists of a set of equipment type and model-specific procedures itemizing the tasks and parts that are required in order to complete periodic inspections, preventive maintenance, and periodic parts replacement. Some organizations use references to service manuals. Others develop typed procedures using word processors and reference those, and still others use sophisticated CMMS-based procedures that use database fields for common tasks and build the procedures as sets of tasks. There is no consensus on the data format for procedures other than those procedures that are model-specific and required for most high-risk devices (e.g., ventilators and complex systems, such as imaging systems).

It is required that technicians performing scheduled maintenance tasks consistently and appropriately test the device being inspected. Most CMMSs allow scheduled maintenance work orders to be generated as individual work order forms with the itemized procedure on the printed work order, or as a list of work orders with a reference to a printed procedure. Many commercial systems provide both options and leave to clinical engineering management the decision to print procedures for each work order.

Parts and Service Provider Management

One of the underlying philosophies of a quality CMMS is that all services be tracked and costs recorded regardless of the service provider. This section describes various ways to track and manage repair parts and vendor services.

Parts One of the ways to categorize repair parts is by the way that they are obtained. Repair parts typically are obtained from one of the following types of sources: Stock parts, parts purchased directly from a vendor and shipped to the hospital for specific use on a specific repair, or parts supplied by the vendor as part of vendor service that includes installation labor.

Stock parts are stored locally for future use. These parts may be stored in a stock room, at a technician's workbench, or in other locations. All clinical engineering departments maintain some stock of electronic components, batteries, wire, nuts, bolts, and other common hardware. Many departments also stock circuit boards and other expensive medical device-specific parts.

Determining the parts to stock or to order on an as-needed (i.e., just-in-time) basis is based on how critical the device is and the ability of the clinical engineering department to obtain specific parts from the source quickly. As it is impossible to predetermine all failures, and as it is cost prohibitive to stock all parts for all devices, major high-cost, low failure-rate parts would not be stocked.

Some clinical engineering departments have purchasing authority and issue their own purchase orders. Purchasing authority, combined with a direct receiving function in clinical engineering and the availability of Federal Express, UPS, or other overnight carriers, frequently allows the ordering and receipt of parts to occur within 24 hours, thus minimizing the need to stock high-cost, low failure-rate parts. However, some clinical engineering departments are still burdened by institutional purchasing protocols that require the purchasing department to preapprove and/or to place parts orders, thereby adding significant delays to the ordering and receipt of parts. Computerized parts management systems are nonstandardized and typically differ a great deal from one department to another and from one institution to another.

CMMS-based parts management software usually requires that all parts entered have a previously issued and unique clinical engineering part number. Alternatively, some systems do not require a unique clinical engineering-generated part number and instead use the manufacturer's part number as the index to the parts management system. Other fields that typically are collected include a part description, price(s), manufacturer, manufacturer part number, vendor, and vendor part number.

Most hospital purchasing and accounting systems are much more complex and require more complex systems to manage parts. For example, some clinical engineering departments stock large numbers of parts and/or high-value parts and require that pricing includes a handling markup to pay for parts stockroom overhead. Other departments may require pricing calculations based on a rolling average price paid when several parts (bought at different times and at different prices) are resold to the clinical engineering customer as part of a repair. Other institutions that rely on purchasing parts quickly and on an as-needed basis may require a reference to a unique purchase order number or purchase order tag number for each purchase.

Service provider management No clinical engineering department can provide 100% of the equipment service that is required, 100% of the time, on 100% of the equipment inventory. In order to control the cost and quality of vendor medical equipment repair and maintenance services, it is appropriate for clinical engineering departments to control and to coordinate vendor equipment services.

Vendor services can consist of nonbillable warranty work, service performed on a fee-for-service basis, service performed under a prepaid service contract, billable services performed under a prepaid service contract but outside the prepaid terms and conditions of the contract, and other billable and nonbillable services (e.g., product recalls and installation work). All costs (e.g., prepaid, billable, freight, tax, parts, and labor) should be tracked.

All vendor service work needs to be coordinated and tracked in a similar manner to the data collected for in-house work. Typically, vendors complete service reports when they have completed a task or when they leave the site even if the task has not been completed. These service reports are among the key documents used for data collection. Service reports should be required by and provided to clinical engineering for all vendor work, both billable and nonbillable.

In addition, billable services typically require a purchase order prior to the vendor providing the service. Billable services also will eventually yield an invoice itemizing pricing. Although estimated pricing for vendor services can be used to track costs, it is much better business practice for clinical engineering departments to receive an invoice, match the invoice with the purchase order and service report, review the charges to make sure that the cost is appropriate for the work that was completed, and then complete the documentation by entering appropriate technical and cost data into the CMMS.

The CMMS requirements become more complex if maintenance insurance, partnership contracts, and other risk-sharing, cost-sharing schemes (e.g., parts caps) are implemented. These typically require keeping track of various terms and conditions that trigger additional costs or rebates, and sometime these triggers accumulate across a large number of devices over several years.

Data Accuracy and Integrity

New equipment entries and equipment service history entries comprise the majority of data collected in a CMMS. Service history data are typically collected by biomedical equipment technicians and then either directly keyboarded into the CMMS or a paper form filled out and data entry clerk keyboards the data into the CMMS. Equipment data can be entered by clerks or technicians from purchase orders or new equipment forms filled out by technicians for later entry by clerks. Service reports from other service providers are entered into the CMMS by technicians or clerks, or they are scanned.

Data entry requirements are intended to optimize data accuracy while minimizing data entry times. Data entry times can be minimized by using defaults and not requiring any redundant entries or keystrokes. Data accuracy and data integrity can be optimized by making the CMMS easy to use correctly, enforcing data integrity rules when appropriate, and establishing operational policies and practices that require every employee to enter accurate and complete data.

Data integrity issues can be further subdivided as follows (Barta, 2001):

- Data integrity enforced by the CMMS
- Data integrity enhanced (but not enforced) by the CMMS
- Data integrity based on department-wide, standardized definitions and operating procedures

Enforced data integrity can be used where flexibility in practice is not required and where an absolute relationship always occurs. This occurs most often in customized CMMSs, where the business rules can be built into the system and the flexibility of being able to match many different institutions' rules are not required. One example of enforced data integrity would be that every parts purchase order must have a valid purchase order number, a valid department, and a valid vendor associated with the order. In every case where there is an absolute requirement for a valid reference field, it is appropriate to enforce data integrity.

Some fields require an entry but do not necessarily reference another table or file. Examples of these required fields are a model and manufacturer for each equipment control number, and start and end dates for each work order. Other types of absolute data enforcement include the correct type of data (e.g., numeric, string, or date), range checking (e.g., valid date checking), and inter-field relationship checking, sometimes called "sanity checks." For example, a work order end date cannot fall before the work order start date.

When data integrity cannot be absolutely enforced by the CMMS because of exceptions or situations that require more flexibility than absolute data integrity allows, it is appropriate to use the same data integrity concepts but with defaults, warnings, or workarounds that allow the user to bypass the data integrity system legally. For example, when a new model is added, the CMMS may display a list of similar models and ask the data entry person to select one of the displayed models as the correct model nomenclature or indicate that the new model entered is indeed a valid new entry. This helps decrease the number of duplicate models inadvertently entered because of subtle differences in the model spelling and the punctuation used; however, this does not preclude the entry of new model names.

Every department that operates a CMMS should have a department-wide set of standardized definitions and operating procedures describing system use, data formats, data measurements, required fields and management's clarification of the ways they want certain tasks documented parts. For example, are transit time and wait time documented as part of a repair work order? This set of standard operating procedures establishes a consistency that cannot be programmed into a CMMS (even a custom CMMS) and makes the CMMS a much more valid and useful management tool.

Reports

The reporting capabilities of a CMMS are the heart and soul of a vendor's product from a management perspective. The ability of the CMMS to produce relevant, informative, concise reports transforms the software into a management tool. When justifying the purchase of a CMMS, a demonstration of reporting capabilities to senior administration is one key to whether or not the deal is consummated (with considerations for price). All successful technology management processes are dependent on the ability to gather data, to aggregate the data to convert it to useful management information, and then to produce reliable decisions based on the information. Reporting is the fundamental communication and decision support tool for the CMMS.

The ability to make the CMMS work toward your specific needs centers on the reporting capabilities of the system. The reporting access structure should be easy to use and intuitive yet offer sufficient reporting power to allow any data field to be aggregated and reported in any manner that the end user feels is appropriate. Typically, a tiered approach is used with canned reports for commonly used reporting requirements (e.g., monthly reports to customers), ad hoc reports for selection of various fields commonly reported (e.g., equipment history reports with date ranges), and custom reports for more complex reporting requirements (e.g., cost benchmarking) that may require some programming skill to generate.

Point-and-click structures should be the reporting baseline with common graphics or symbols that are easily recognizable and understood regardless of the computer literacy of the staff. Microsoft Windows®-based structures are one way to provide familiarity and user friendliness. More advanced reporting tools also may use a structured query language (e.g., SQL) to extract data from the database and additional (often third-party) reporting tools (e.g., Crystal Reports®) to format and write the report. The CMMS must have a reliable query process that allows an interface with the main database for all required reports. Reports should have the capability not only to print out on to paper but also to view on screen and to publish them as computer-transmittable files (e.g., pdf files) or web pages (e.g., html files).

All CMMS products will have generic reports. A review of the vendor's generic reports may reveal a need for reports that are specific to your health care facility. Specific reports can be generated with user-defined fields or through custom reports written by the vendor, a third party, internally by information technology (IT) or clinical engineering department staff depending on resources available, and the report writing tools that are available in the CMMS. The authors recommend that an agreement with the original vendor be included in the contract price for all initially required custom reports. Third-party software vendors charge as much as \$50,000 for each customized report. Pop-up displays that are triggered by indicator limits provide a dashboard for decision support and management control. (See Chapter 100.)

The CMMS must be capable of satisfying regulatory reporting requirements, particularly those of the Joint Commission for the Accreditation of Healthcare Organizations (JCAHO), the Food and Drug Administration (FDA) (see Chapter 126), and state and local health agencies. The basic reporting structure for clinical engineering should include an inventory list for all medical equipment, a work order generation and completion process, risk-ranking of medical devices, preventive maintenance scheduling, personnel time allocation, and resource allocation (both physical and personnel). Table 36-1 lists many commonly used reports produced by a CMMS.

Utilities

A utility is a computer program that is not contained in the main operating system (OS) or the core CMMS and that provides an essential function or feature. In most cases, as customers demand similar utilities, the programs are incorporated into the OS and/or CMMS, but during selection of the CMMS for your facility it is wise to have a checklist of required features.

Features that are required but not contained in the OS or core CMMS should be available from the vendor as utilities. Examples of utilities are database validation, database diagnostics, security features, global data changes (e.g., manufacturer A merges with manufacturer B), user-defined fields, initial installation, setup, database conversion from a previous vintage or foreign vendor's CMMS, and configuration programs.

The system administrator has access to the utilities programs and will become familiar with their functions. General CMMS users most likely will not be aware of, or have access to, utilities programs. As the needs of the facility change, available utilities programs allow the CMMS to become flexible and scalable. The addition of a utilities program allows a system to grow as needs change, without the expense of replacing the entire system. This is an important purchase consideration that should be explored thoroughly.

Network and Multiuser Issues

All but the smallest of clinical engineering departments will require more than one user with simultaneous access to the CMMS. The connectivity and throughput capabilities of the CMMS will be determined by the existing network, or by the funding that is available to purchase and install the recommended network infrastructure. Prospective CMMS vendors should provide network bandwidth requirements for their systems. The vendor should be asked for complete technical specifications, and these specifications should be reviewed with the IT department.

The optimal CMMS vendor selection process should involve a committee that includes a staff member from the IT department. Begin with a list of multiuser needs and expectations. Is there a need for telecommuter system access? Does the enterprise consist of a single facility or multiple local or remote facilities with varying telecommunications capabilities? Who are its customers? Who are the system users? How many workstations will be required? After answering these questions, compare those needs to the system capabilities and the institution's current network infrastructure. Can the desired system be achieved within the existing infrastructure? If not, what will it cost to provide a network that is capable of meeting the needs? Will funding to upgrade the network be available?

Assuming that the funding and/or the network is suitable for the needs of the organization, review the available networking technology. Are there areas where a wireless interface is more cost-effective, or will the entire network be hardwired? Will the system be run on an intranet corporate enterprise network, a web-based network, a local area network (LAN), or a combination of these technologies?

Most CMMSs will use a client/server, local area network (LAN) structure for multiuser access. The client/server system consists of a main server (or multiple servers if the CMMS is operating across multiple facilities) and several workstations that typically are interconnected via a cabled network. The typical workstation will be the personal computers (PCs) in your work areas and will be used to run the CMMS client and other desktop-based applications (e.g., word processor, spreadsheet, and calendar). The server is a more robust computer with the power and memory to host and drive the entire system. All CMMS data will be stored on the server and will be sent to the client workstations on an as-needed basis. The server may be located in the clinical engineering or information technology departments. It is managed by the system administrator.

For those mobile users who cannot often access a LAN-connected workstation, most CMMS vendors offer a laptop, standalone version that can be periodically, intermittently connected to and resynchronized with the server.

Data Telecommunications Technology Primer

Most hospitals will have existing network infrastructure (e.g., cabling, routers, switches, and hubs). If applications are required for remote workstation interfaces (i.e., those outside the LAN framework), an understanding of the available Local Exchange Carrier (LEC) telecommunications infrastructure is essential. LEC is a local telephone company or competing company that can provide the desired connectivity.

For connectivity over longer distances than the internal wired LAN/WAN, there are a variety of telecommunication options including microwave, optical, and various wired technologies. Microwave connections can be considered only for short (line-of-sight) distances of less than three miles. Rain, snow, fog, birds, and bats can cause network interruptions of microwave transmissions. Infrared transmission, known as Freespace Infrared Local Area Network (FIRLAN), also can be used for remote connection to the LAN. FIRLAN's advantages and disadvantages are similar to those of microwave, and installation costs can run above \$20,000. These types of remote interconnections to the LAN are known as point-to-point connections. Figure 36-1 illustrates a generic point-to-point telecommunications system.

Table 36-1 Common CMMS reporting capabilities

Complete equipment inventory listing	Productivity report by technician by date	List of vendor sources for repair parts by inventory number
Print scheduled PMs	Incomplete work orders by assigned technician, department, and date	List of equipment manufacturers by equipment type and model
List of open, suspended, closed work orders by department, technician, and date	Estimated PM hours by facility by date	Graph bar chart corrective repair costs vs. PM costs by date
Total work orders by facility by date	Life-cycle costing by inventory number by date	Graph bar chart corrective repair costs vs. PM costs by date by inventory number
Total work orders completed by technician by date	FTE estimate based on estimated PM hours by facility by date	Personnel listing technician wage/salary, start date, certifications, OEM schools attended
PM completion percent by date	FTE estimate based on current corrective repairs by facility by date	Personnel listing vacation and sick hours available
PM completion percent by cost center by date	Total dollar amount for equipment in inventory	Risk management SMDA reportable events by department by date
Total parts cost by inventory number by date	List of equipment by equipment type, category	Risk management SMDA reportable events by date
Total corrective hours by inventory number by date	Weekly productivity by technician by date	Risk management SMDA reportable events by inventory number by date
Incomplete PMs by technician by date	Graph line chart of total inventory by date (from date to date)	Risk management SMDA reportable events by equipment category
Incomplete PMs total number by date	Graph line chart of total inventory asset dollar value by date (from date to date)	Graph pie chart of resources by PM hours and corrective hours by facility by date
Performance indicator reports (e.g., down time, response time)	Ratio of repair and maintenance cost to acquisition cost by type of equipment	Purchase order by vendor by date

Figure 36-1 Point-to-point remote communications.

The rate of uninterrupted flow of information is known as “throughput.” Throughput is directly related to available bandwidth and router capacity. Table 36-2 illustrates the various LEC services and their bandwidth limitations.

The primary network issues involving the installation of a CMMS will involve the local area network (LAN) and access to a server. A network consists of nodes (i.e., workstations), hubs, media access unit (MAU), bridges, routers, and gateways that are linked together for the purpose of transmitting data from one location to another. LANs provide a robust, flexible, and scalable means to interconnect all users of the CMMS. Although LAN standards are beyond the scope of this chapter, further in-depth information concerning LAN specifications can be found in the Institute of Electrical and Electronics Engineering (IEEE) 802 family of standards.

LANs are constructed in specific layouts or connection pathways known as topologies. The major LAN topologies are mesh, star, ring, and bus. Figure 36-2 illustrates each of these topologies, which provides a visual concept of the way that various networks are linked together.

The bus and ring topologies are the most common LANs. Star and mesh topologies are more expensive because of the increased number of links in the network. Bus and ring topologies are well-suited for CMMS applications. Bus topology with standard Ethernet (10Mb/sec) or high-speed Ethernet (100Mb/sec) are the most commonly used LAN infrastructure for CMMS applications.

The principle of ring topology involves a “token,” which contains requested information and is passed around the ring until it is accepted by the originator of the request (i.e., the workstation). Ring topology ensures uniform distribution of requested information and guards against bandwidth saturation. Both shielded and unshielded twisted pairs can be used at transmission rates up to 16 Mbps, which is somewhat higher than standard Ethernet bandwidth. Bus topology has an advantage of simplicity for maintenance, but access depends on the position of the workstation on the bus.

Each LAN will have one access method and one or more specified physical media and topology. The most typical LAN uses bus topology and Ethernet. Ethernet uses carrier sense multiple access with collision detection (CSMA/CD) as the access method. Ethernet refers to the physical link and data link protocol for LAN interconnection. The physical connection may be a twisted pair or a coaxial cable. The maximum transmission rate of an Ethernet link is 14,800–64 byte packets per second (PPS) or more commonly 10 Mbps. Ethernet connections which use twisted pair phone wires will have an RJ 45 connection at the terminal end and are known as “10base-T.” High-speed Ethernet, which has a transmission speed of 100 Mbps, is known as 100base-T. If the facility has sufficient network infrastructure to meet the bandwidth requirements of the CMMS, then the clinical engineering department should use that infrastructure. Table 36-3 provides a comparison of physical media and LAN topology characteristics.

In some instances, it may be cost effective for the facility to purchase one CMMS, which can be utilized by multiple service departments such as IT, physical plant, and clinical engineering. Difficulties arise in this scenario because of multiple departmental regulatory reporting requirements and variations in project priorities. If a single server is used, the drive should be segmented by department in order to allow easy access to information pertaining to a specific department. Without segmentation, all data are lumped into one large pool. The queuing factors must sort through several lists before the specific required information is retrieved. Although it is more expensive, a dedicated server for each department eliminates several software conflicts; is simpler to install, customize, upgrade, and maintain; and reduces problems with throughput.

Additional challenges of a multiuser network involve access levels and access security. The system administrator is required to have access to all features and functions and to manage security and access for the other staff. The manager and supervisors, administrative assistant/clerical/dispatch, and technician staff all may have access to some common features and some others that are dependent on their access group. If a nurse manager is concerned about a shortage of vital signs monitors, a read-only access level provides information on the repair status for a specific piece of equipment. Allowing clinical staff read-only access to CMMS inventory and work order status screens is an efficient com-

munications and management tool. End user access to enter new repair work order requests also can be useful.

The system administrator will have the highest access level that is capable of performing all CMMS functions. A supervisor access level just below the system administrator should be available for managers. This level of access provides reporting capabilities and sensitive personnel information concerning salary, date of hire, home telephone number, and other personal information.

General access should be available to all technicians and engineers in the CE department. Personnel outside the department should be given read-only access. Personnel without a knowledge of the way a department functions or the way the CMMS operates might unknowingly modify or delete important data fields or files and corrupt the database. Senior administration might wish to have access to some of the reporting capabilities of the system. Again, a read-only access level is the prudent approach for system entry.

Although most CMMS systems will not contain patient information, system security must be included (see Chapter 104). As mentioned earlier, there could be sensitive personnel information in the database, and users who are unfamiliar with the system might induce errors that would require reentering information. General security methods using password protection are sufficient safeguards to prevent unauthorized entry into the CMMS. Firewall protection must be considered if Internet access is linked to the system or if the CMMS interfaces with another network.

New Technologies

Innovations and new applications of existing telecommunications and computing technology are emerging at a rapid pace. To state that new technology is being implemented is relevant only when describing the comparison to a facility’s existing technology and, then, only in a specific and short time period. The Internet and Computer Telephony Integration (CTI) are perpetual, cutting-edge concepts that continually infuse new technology into the mainstream of networking.

When electronics nanotechnology is added to these rapid transformations, the world of networking takes on new meaning almost daily.

The most dramatic impact in telecommunications has come from, and will continue to come from, deregulation ushered in by the Telecommunications Act of 1996 and the resulting impetus for development of additional infrastructure. Satellite communication, fiber optics, ISDN, DSL, and a host of other, faster broadband communication technologies are bringing more and more data to homes and businesses at a faster and faster rate. Web-based programs offer flexibility and accessibility unparalleled by any existing hard-wired LAN system. Virtual Private Networks (VPNs) offer the opportunity to have LAN types of applications on a worldwide scale. The availability of wireless network links (e.g., 802.11 Ethernet and Bluetooth) undoubtedly will be included in the networks of the future. Remote and distributed computing technologies will overcome problems with scalability, performance, and cost, the bane of hard-wired networks.

Technologies that are currently available but not widely utilized in CMMSs include personal digital assistants (PDAs), CMMS-like software embedded in test and analysis equipment, bar-coding interfaces, remote diagnostics, service manuals and operator manuals residing on a server or web site, e-mail interfaces, video, technical and clinical in-services, and web-based CMMS programs.

Several CMMS vendors have interfaced PDAs and similar handheld or wearable workstations to their applications. These new portable devices can provide additional features with their built-in and add-on CMMS and other common computer applications (e.g., word processing, calendar, and spreadsheet). The CMMS applications for the PDAs and similar devices range from the full CMMS inventory and maintenance data to selected records determined by the CE staff using the PDA. Touch screen technologies, speech recognition, and voice-in and -out add to the user-interface features. Synchronization is

Table 36-2 Comparison of communication network technology utilized for point-to-point connections

Service	Carrier/medium	Bandwidth	Data Integrity	Application (s)
PSTN (standard phone cable network)	4-wire dedicated	56Kbps	Moderate to very good	Remote PC/workstation to LAN PC
Full T-1 24 digital channels	T-1	64 Kbps/channel	Excellent	Supports video capabilities. Only fractional T-1 required for most CMMS applications
Switched 56	Fractional T-1	56 Kbps	Moderate to very good	Remote PC/workstation to LAN
BRI	ISDN (2 B + D)	128 Kbps	Excellent	Must have an ISDN interface for legacy equipment
Frame Relay	ISDN 2-wire	64-128 Kbps	Excellent	Also supports wireless applications
Broadband	Optical fiber & ATM	>1.5 Mbps	Excellent	Supports video applications. Not required for general CMMS applications

Interlinking system of the mesh topology

Figure 36-2 Mesh, star, ring, and bus topology.

by intermittent, ad hoc connection to the CMMS LAN, but wireless network capability (e.g., 802.11 wireless Ethernet) for these portable CMMS devices is on the horizon. Challenges for these devices continue to be the following: Data management (e.g., sending extracts of the CMMS database or the entire database to the PDA and the concomitant memory size issues); nonstandard display size and resolution; touch screen keyboard; nonstandard keyboards and keyboard size; cost versus durability (e.g., the ability to withstand a drop to the floor); and battery life, which is typically shorter than an eight-hour work day.

Several CMMS vendors have interfaced PM software into test and analysis equipment for paperless maintenance inspections, work orders, and electrical safety testing. Historically, these systems have focused on electrical safety testing and storing electrical safety leakage? current values, which has limited, if any, legal or practical application. Automated integration of test equipment with a CMMS application may have some application where there are large numbers of devices that can be automatically tested and certain limited, critical data values stored.

Bar coding has been used by CMMSs for many years. Bar code systems and readers have improved to the point at which they are useful for equipment and parts inventory control and may have some utility in work order management.

Various paging systems have been interfaced to CMMSs to allow automatic paging based on user entry of work orders and directed paging based on staff availability schedules and other data. As cellular phones, pagers, PDAs and other devices become integrated, there is an opportunity to develop a "technician communication tool" that combines several of the features discussed here as individual products. To be most useful, such a product would need to have seamless wireless network access to the full CMMS (e.g., IEEE 802.11 wireless Ethernet).

Another new technology is the application service provider (ASP). ASPs are software applications running remotely at a vendor's site that are accessed by the end-user in a fashion that is similar to the way applications are accessed by a LAN. A CMMS ASP would look little different from a LAN CMMS, with a web browser as the graphical user interface (GUI) to the CMMS. The vendor of the ASP takes care of all access and security issues as well as backups, upgrades, and regular data maintenance. Fee structures are under development and include fees based on the amount of data stored, the number of users, bandwidth requirements, and other parameters. Security enhancements for these shared remote networks are under development.

Conclusions

Information and communication technologies are rapidly changing. The CMMS technology market is relatively small and somewhat mature. Accordingly, changes occur much more slowly. CMMSs most likely will not drive the wireless communication infrastructure development in health care institutions, but once the wireless infrastructure is in place, clinical engineering departments and CMMS vendors will be able to take advantage of them and offer much more robust portable applications.

Until then, new developments will be incremental improvements in software as well as and new decision support tools to help convert the large amount of data collected to useful information for managing technology.

Defining Terms

Asynchronous Transfer Mode: A high-speed network that provides optimal multimedia transmission at prohibitive costs

Bridge: An electronic device that interconnects two disparate LANs

Bus Network: A network topology where all workstations are attached to the same main physical medium (wire or cable)

Coaxial cable: A shielded cable for linking nodes within the network

Database: An accumulation of information stored in an orderly protocol, which can be accessed through a query application, updated, and viewed

DSL: Digital Subscriber Line.

Ethernet: The physical link and data link protocol for LAN interconnection. One of the oldest and most cost-effective network links

Graphical User Interface (GUI): A graphical tool that provides the user with point-and-click, intuitive characters, or icons to control the actions of the computer

Hub: A network node, which serves as a multipoint repeater to other links in the network

Hypertext Transfer Protocol (HTTP): A computer standard, which allows computers operating in different environments to transfer data

ISDN: Integrated Services Digital Network

Intranet: A private network utilizing Internet-based technologies within an organization or enterprise

Local Area Network (LAN): A group of computers sharing a common database and/or server for a common purpose, forming nodes connected by a physical medium

Local Exchange Carrier (LEC): The local telephone companies or competing companies that can provide a user with the desired connectivity. In telephony jargon, they are divided into "incumbent LECs" (ILECs—the companies that have a majority of the local business) and "competitive LECs" (CLECs—the companies that compete for more of the ILECs business)

Network: A system of nodes (i.e., workstations, hubs, routers, bridges, and gateways) that are linked together for the purpose of transmitting information (e.g., voice, data, and video) from one location to another

Server: A more robust computer that has the horsepower to drive the entire system

Throughput: The rate of uninterrupted flow of information

Topology: The construction or physical geometric pattern of specific layouts (connection pathways) for a LAN

User-defined field: An open field that allows the user of a CMMS program to determine the characteristics of the queuing requirements and display outputs

Table 36-3 Physical media vs LAN topology comparison

Topology	Bus, star, or ring	Bus or ring	Bus or ring	Bus, star, or ring
Physical medium	Twisted pair	Baseband coaxial cable	Baseband coaxial cable	Fiber
Maximum nodes	About 250	About 1000	3,000-4,000	3,000-4,000
Available channels	Single channel	Single channel	Multichannel	Multichannel
Maximum transmission rate	100 Mbps	100 Mbps	400 Mbps	Several Gbps
Disadvantages	Lesser bandwidth, susceptible to noise	Susceptible to noise	Expensive, requires headend set up	Expensive, specialized training
Advantages	Low cost	Ease of installation	Transmission of voice, data, and video	Transmission of voice, data, and video

Utility: A small computer program, not contained in the operating system (OS), that provides an essential function or feature

Maintenance and Repair of Medical Devices

James McCauley

Director, Biomedical Engineering,
Central Coast Hospital
Gosford, New South Wales, Australia

This chapter looks at ways in which maintenance and repair activity may be managed. No hard and fast rules are set; rather, a more general approach is adopted. The reason for this is to encourage those who are responsible for managing or providing maintenance and repair services to think in a wider context so that they may have confidence to develop and explore different strategies or ideas. Furthermore, this chapter makes no attempt to be either specific or comprehensive nor to define any existing requirements, for to do so would ensure obsolescence in a rapidly changing world.

Maintenance and repair activity is required in order to ensure that devices are kept functioning within the limits imposed by the test criteria and to return devices to the required level of functioning after breakage or other failure. Additionally, safety and performance testing is required in order to identify unsafe or incorrectly performing medical devices that could pose a risk to either patients or staff. Such testing is usually performed at acceptance and then on a routine basis. Together, safety and performance testing and maintenance and repair form the basis for any medical device management program. (See Chapter 122.) However, the two are often seen as quite separate activities, as safety and performance testing is often mandated (typically every 12 months), while maintenance and repair activity is usually performed in reaction to device breakage or failure. In practice, maintenance and repair are generally managed differently from the way safety and performance testing are managed. Although maintenance and repair are viewed as basic “bread and butter” activities, they are in fact more like “chalk and cheese.” They are opposite sides of the same coin and almost the antithesis of each other. “Maintain” comes from the Latin “to hold in one’s hand,” meaning to protect and look after. “Repair,” on the other hand, means to return things to the way they were, to make better, or to fix. The primary goal of maintenance activity is to reduce or if possible to eliminate, the need for repairs.

Unfortunately, it will never be possible to reduce repair activity to zero, despite effective maintenance programs that eliminate foreseeable problems and that keep devices functioning within acceptable safety and performance criteria. Random component failure will never be entirely eradicated, and the practical reality ensures that devices will be broken in use, despite staff training or attitude. On the other hand, it is possible to reduce maintenance activity to zero, in which case all available resources are allocated to repairs (and to required routine safety and performance testing). In fact, once resources are limited, many organizations tend to slide toward a low-maintenance and high-repair outcome. Once repairs reach a certain level, it could be difficult to continue any maintenance plan or balance repairs with routine safety and performance testing. If it were not for mandatory or professional obligations, some organizations could end up doing little safety and performance testing and end up operating on “run ‘til failure” mode. While such a strategy is clinically unacceptable, it may be the most efficient in terms of equipment management cost and adequate resource allocation, for medical device management is often difficult to achieve in the health care environment. Only when clinical service delivery or statutory obligations cannot be maintained—possibly leading to income

reduction or increased exposure to liability—does funding for medical device management take priority over clinical needs.

Medical device management is funded by many methods. These include historical funding, funding based on the number and type of devices, funding based on the number and type of beds and services in a health care organization, or a combination of these and other factors such as various “insurance” schemes. (See Chapter 39.) Regardless of whether an organization performs maintenance and repair “in-house” or contracts some or all of this service out by whatever means, it is essential to understand the way in which funding is obtained and allocated. (See Chapter 48.) This perspective helps adequate resources to be sourced, distributed, and retained to meet the ongoing changes in medical device management requirements.

Framework Guiding Maintenance and Repair

Regulation

Before maintenance and repair work is carried out, it is important to establish the regulatory framework under which such work is to be undertaken, to ensure compliance with local requirements. (See Chapter 124.) Requirements vary according to location, the type of equipment being managed, the nature of the health care organization’s operation, and possibly among different manufacturers. In some countries there is little regulation, and work might be carried out by any capable person, regardless of qualifications, experience, or training. To some extent this situation exists almost everywhere, as some organizations employ (or contract out to) repair personnel who have had limited training, opting instead to provide skilled supervision so that people who have minimal qualifications can do the job. (See Chapter 38.) Some countries regulate the registration of technical personnel, including supervising personnel, and might further regulate repair and maintenance to the extent that these activities can be audited to ensure that quality control is maintained. (See Chapters 19 and 27.) Auditing can extend beyond the country of manufacture such that all repairs undertaken by the manufacturer or supplier are open to being audited, regardless of where they are performed (particularly if there is a chance that the device could re-enter the country of manufacture), with penalties if quality standards are breached. (See Chapter 126.) In such instances, manufacturers will seldom take responsibility for maintenance and repair performed by unknown personnel. (See Chapter 13.)

In addition, there are various standards (see Chapter 117) that govern medical device management, and most countries adopt at least one such standard, either as part of the overall quality process or more rigorously as a legislative requirement. Typically, such standards define the nature and frequency of safety and performance testing but do not

define maintenance requirements other than in the most general terms. These standards seldom if ever define repair quality issues.

The personnel who are responsible for medical device management programs should be well informed as to the regulatory requirements in their area. Further, they should know whether there are requirements covering the qualifications of technical personnel and whether standards exist to cover maintenance and repair procedures. If all requirements covering device management can be met, then the recipient health care organization should meet reasonable public expectation for quality health care delivery, given local circumstances, and should have its capability assured.

Risk Management

The reality of many medical device management programs is that they are relatively under-resourced, particularly with the adoption of more, and more complex, technology. This presents a difficult situation. If scarce resources are allocated to yearly safety and performance testing, perhaps for mandatory or accreditation reasons, then the repair backlog may increase to a level where clinical service delivery becomes affected. Also, if the repair backlog increases, then maintenance activity will reduce, thus compounding the problem.

In order to operate with limited resources, various techniques have been adopted to justify reduced safety and performance testing frequencies and to define maintenance requirements more precisely (Fennigkoh and Smith, 1989; Fennigkoh and Lagerman, 1997; Gullikson, David and Blair, 1997). These techniques have included classifying the maintenance needs of items or protocols for justifying the extension of safety and performance testing intervals. These techniques rely either on some measure of device "criticality" risk analysis or on sound statistical reliability data. Usually, insufficient data are available for valid statistical analysis, and these techniques then must be based on risk-management techniques. Risk management typically involves developing a "matrix" with the probability of failure along one axis and the consequence of failure (from minor to major) along another. Devices can be placed in the matrix according to where they sit on each axis and ranked, allowing resources to be targeted at the highest risk items (i.e., those where both the probability and consequence of failure are highest). The rationale behind any technique adopted should always be documented. (See also Chapter 56.)

Maintenance Strategy

Regardless of the technique adopted to balance available resources against "risk," fundamental maintenance and calibration strategies will help to improve device management efficiency over time. Further innovative strategies should always be sought out and considered, particularly if they bring increases in efficiency, as any increase in efficiency can reduce the overall risk.

One fundamental step is to move toward "standardization" of the devices being managed and to reduce the different types of devices found across a health care organization. This may be done without compromising service delivery, while still allowing a degree of clinical choice. If implemented carefully, it will benefit an organization because there will be less variation in maintenance and repair requirements, thus allowing limited resources to be more effectively applied. Staff training (both technical and clinical) can become more focused. Such a strategy seldom needs justification. For the maintenance and repair service provider or medical device manager to have the most valuable insight into this process, they need clinical knowledge as well as technical familiarity with the devices being used.

Pre-purchase estimation of projected maintenance costs needs to be considered, particularly as these costs often can exceed the capital cost of the equipment over its lifetime. (See Chapter 30.) Although often overlooked by clinical staff and management, it should be an essential consideration in any procurement process. If the maintenance requirements can be paralleled with existing equipment (e.g., by using the same type of batteries or other components), then such factors should be investigated because it might be possible to reduce overall long-term labor and parts costs.

"Ownership" of the equipment is another issue to be considered. Is equipment "pooled," or does it belong to a particular ward or other location? Often there is a mix of ownership across a health care organization. Whatever ownership model is employed, it will have implications when it comes to locating equipment and to the funding of maintenance and repair. No single strategy has emerged as the best. Ownership is often defined as part of the health care organization's broader business process. This reality and staff sentiment often make it hard to change ownership patterns. With vigilance, areas where the current ownership practices are impeding efficient device management can be identified, and different practices possibly can be adopted. Any maintenance and repair service provider should be prepared to adapt to existing conditions.

Other strategies to consider include balancing the level of support against available technical capability, both internal and external. In some countries, health care organizations find it almost impossible to obtain any technical support for their medical devices, while in other countries the capability and availability of such services are high. Scrutiny of all technical resources available to a given locality is essential in order to ensure that the highest quality and most cost-effective service are provided to the health care organization.

There always will be new and different strategies to consider. Some of these will be brought about by changes to technology and improvements in device management techniques. Others will be brought about by changes in financial or business requirements. No single strategy should be considered sacrosanct, and new strategies always should be considered or sought out.

Linking Maintenance Requirements to Test Schedules

One major problem in managing medical equipment is difficulty in obtaining the equipment when needed. Often equipment is in use, or a particular device might be impossible

to locate. Different organizations have adopted various strategies to help ensure that all equipment is tested when required, with differing degrees of success. The best strategies often depend largely on local knowledge and contacts. Nevertheless, obtaining access to the equipment can be a time-consuming exercise and is often a major and unaccounted for drain on resources.

The simplest and possibly least developed option is to link maintenance activity to safety and performance testing. Safety and performance testing of all devices is usually required at least every 12 months. More recently, this period has been extended for some devices based on reliability and failure analysis. Certain maintenance procedures for particular devices are required more frequently than every 12 months and some might be required less frequently. For certain types of equipment, maintenance is based on occasions of usage or on hours in service.

With thought, most maintenance can be included in the routine testing schedule regardless of the way the test schedule is managed. It is not whether, but how, maintenance is included that leads to increases in efficiency without increasing risk. Battery replacement is a good example to illustrate this point. Typically, devices with batteries require some form of battery capacity check for battery deterioration. One way to perform such a check as part of routine testing is to ensure that the devices are first fully charged and then left functioning for a set period. If during this time the battery voltage drops below a certain level, usually indicated by the low-battery alarm, the battery is deemed to have insufficient capacity and must be replaced. This is a time consuming process for testing personnel, who must fully charge the battery, discharge it (perhaps over several hours), and then recharge the battery before returning the device to service. One alternative strategy would be to replace batteries beyond a certain age. Assuming that good quality batteries are available, which has become harder to guarantee, then instead of testing the capacity of each battery, a policy of changing batteries that are over 18 months old could be adopted. In this case, given yearly testing, no battery in service would be over 30 months old. While there are arguments for and against both strategies based on risk, cost, and efficiency, this example serves to illustrate that there are different ways to incorporate maintenance into the routine testing schedule. Different strategies could be developed for virtually all maintenance activities. The astute maintenance and repair service provider or device manager should consider adopting different maintenance strategies if this leads to increased efficiency, provided that risk does not increase unacceptably, as any increase in efficiency can be used to improve overall device management.

Maintenance Planning

Forward planning of maintenance procedures is important. This process requires detailed knowledge of maintenance requirements and the resources that are required in order to perform maintenance. The resources required include labor, parts, materials, and tool costs. If maintenance is contracted, then all of these costs are often rolled into one by the contractor, although with some contracts parts costs might be kept separate.

Not all computer databases used for medical device management allow for the forward planning of maintenance requirements. Industrial maintenance databases, possibly designed for the production industry, are often good at forward maintenance planning and estimating forward resource requirements, but they tend to lack the required functionality of dedicated medical device management databases. The database system in use will determine how sophisticated forward maintenance planning can become. (See Chapter 36.) Nevertheless, regardless of the database or methodology used, even gross attempts at forward planning of maintenance requirements can benefit both the provider of the service and the recipient health care organization. These benefits include better budget forecasting, the opportunity to identify items that might no longer be cost-effective to maintain, and the potential to rationalize maintenance expenditure across an organization. To establish maintenance requirements, the current condition and maintenance history must be determined for the devices to be managed. If no reliable maintenance history is available, then inspection and condition monitoring, or testing, can help to establish the status of a device. In order to obtain an overall assessment of maintenance requirements in an organization, a "walk through" review of all areas with medical devices is beneficial. It helps to establish the conditions under which devices are being used or stored. This is important because many devices have particular usage or storage requirements, such as needing to be left on charge or in an upright position; if these requirements are not being observed (for whatever reason), then this will have implications for maintenance and repair management. Areas where limited "user maintenance" of devices is possible should be encouraged or instigated if confidence in the capability of users can be assured. This will free up resources, give a certain degree of ownership and responsibility to users, and reduce the need for repairs.

Maintenance planning should be realistic and achievable. Planning initially should focus on major generic maintenance requirements, such as battery replacement, and also on the most critical items, such as ventilators. By tackling the major maintenance requirements first, any increases in efficiency will result in improved availability of resources, allowing smaller (and perhaps more difficult) issues to be tackled. It also will have the added intangible benefit of increasing confidence. With time and confidence, maintenance and repair providers or managers will move from prescriptive and reactive strategies to more creative and proactive management techniques. In doing so, capacity and capability will increase, and the ability to adapt to changing conditions will improve.

Repair Strategy

Fault Diagnosis

Accurate fault diagnosis is critical and may be simple or extremely complicated. (See Chapter 59.) Damage to a device or lack of functionality may be apparent. However, the root cause of many faults is not readily apparent, leaving repair personnel reliant on their

skills and experience to accurately identify the cause. (See Chapter 55.) As the actual fault might have been caused by disconnected factors, it is important to keep a broad view when trying to identify causes. For example, a blown fuse could be the result of an internal component failure but also could be the result of a transient spike on the power supply, beyond control. Furthermore, with experience, the cause of certain faults becomes more apparent, or certain strategies become more effective. The old adage "If no fault is found in the power supply, then check the power supply" sums up the value of experience when trying to diagnose faults correctly. Should the cause of a fault not be readily apparent, then a strategy needs to be followed. The purpose of such a strategy is to identify accurately the cause of the fault in the least possible time so that the appropriate repair can be made.

If possible, information from a user about the fault should be obtained. This information may be communicated directly by the user or it may be written on some sort of fault tag. One should carefully evaluate the information provided by the user because it may be invaluable in accurately identifying the cause of the fault, or it could be confusing and incorrect and could lead repair staff in the wrong direction.

One should try to replicate the fault if it is safe to do so. The fault might be simple to replicate (e.g., "the device won't turn on") or more complicated (e.g., "the external pacer injector does not appear to be in synch with this patient's ECG"). Complicated faults might be difficult to identify, as the fault may only present under certain clinical conditions or with particular types of patients. Nevertheless, if the fault is linked to a clinical procedure (for example, "this thermometer reads high"), then one should be wary, because the device actually might be functioning correctly and clinical staff are relying on preconceived perceptions of the patient's condition rather than the device. A real fault must never be discounted.

Should any type of fault be unable to be replicated, then one may assume that user error is to blame. Such faults may have their origin either in inadequate knowledge of the operation of the device or accidental user error. To jump to either conclusion might be premature, and many service personnel will have experienced the embarrassment of having blamed the user only to later identify a genuine fault with the device. If user error is to blame, then it is important to try to prevent this from recurring. Often a strategic label may be the best way to eliminate the problem, particularly if certain functions of a device are ambiguous or not easy to identify. (See Chapter 83.) Furthermore, simple modification could prevent the problem from recurring. If user error is to blame, then issues surrounding staff training need to be considered.

Most modern microprocessor-controlled equipment may contain service menus, error logs, or diagnostic modes of operation. These may be accessed either directly through the device or by some link to a diagnostic program contained in a remote computer. Repair staff should be familiar with, and should have access to, all possible methods of fault identification. Often the only way to identify intermittent faults is by these means, particularly if there is a device history that might contain an error log.

There might be more than one fault. Perhaps there was fluid ingress or further mechanical damage? Maybe one fault will not become apparent until another has been fixed. The permutations and combinations are limitless, but with experience and by relying on objective analysis, most faults eventually can be found.

Fault Rectification: Repair

The level to which any repair is undertaken is a combination of technical skill, parts availability, clinical need, and cost. Repairs should be performed only when personnel have sufficient training, technical information, tools, test equipment, and parts. Should any of these factors be lacking, then the repair should be performed elsewhere or delayed until these factors become available. It is important to establish boundaries as to what type of repairs will be attempted. Should an overly ambitious repair be attempted, then time and spare parts could be wasted if the repair is unsuccessful, or the safety of the device could be compromised. With modern, multilayer circuit boards and programmable surface-mount components, often the only option is to swap the board and to have the faulty one repaired by the original equipment manufacturer.

Technical skill is a combination of training and experience. All training will improve technical skill, and both general and specialized training should be made available. Experience comes with time, but the experience of others may be used. Establishing good relationships with suppliers and other repair organizations can be invaluable. Attempts at

either formal or informal "networking" will allow exchange of ideas, experience, and information. Staff members should be encouraged to "network" because it will increase their knowledge and improve their skill.

Obtaining the required technical information can be difficult. Should diagrams, schematics and component information be unavailable, it may be impossible to effect a repair, regardless of technical skill. Nevertheless, all devices will have comprehensive service information somewhere. Unfortunately, this is not always readily available; and even if service information is required to be supplied as part of the procurement process, it might lack sufficient detail to perform a repair in the future. Some manufacturers provide technical information on CD or make it available over the Internet. These sources may be used to good effect.

Having the correct, high-quality tools and the proper test equipment is imperative. While a poor workman may blame his tools, a good workman will not use poor-quality tools. Simple things like good quality screwdrivers prevent damage to screw heads, thus allowing the device to be maintained and repaired many times without causing worry about extracting damaged screws in the future. Electrical static protection is also important because static can either weaken or damage electronic components, thus resulting in unforeseen or premature device failure.

Parts availability and storage is a complicated issue, for consideration must be given to supply time, quality, and stock levels. Repair time is minimized by keeping common parts on hand. However, this may lead to devices of considerable capital value sitting idle, with some parts becoming obsolete in time. Whether to use parts supplied by the original equipment manufacturer or by "second sources" always presents a dilemma. So does the level to which parts are held as stock, or obtained as required, particularly as some parts may be difficult to obtain rapidly or may deteriorate with time. Parts salvaged from devices destined for disposal, or reconditioned components, could be used for repairs. Such a strategy could improve availability of parts, but quality and long-term reliability could be compromised. A parts strategy that minimizes repair turnaround time but that also is financially efficient and safe must be developed.

Testing

After any maintenance procedure or repair, testing is required in order to ensure that the device is safe and performing up to specifications. Whether a full safety and performance test should be run is a matter for professional judgement, dependent on the level of repair. Furthermore, consideration should be given to "soak" testing repaired devices by leaving them functioning for a considerable time, particularly if the original fault was intermittent.

Conclusion

This chapter reviews some of the more general aspects of maintenance and repair management. This will lead those who are responsible for maintenance and repair of medical devices to look to different or innovative strategies or options, rather than being introspective, when trying to address the considerable and crucial demands of managing medical devices.

A Strategy to Maintain Essential Medical Equipment in Developing Countries

Michael Cheng

Health Technology Management
Ottawa, Ontario, Canada

Basic medical equipment is now widely used in the district health facilities of developing countries. This large volume of essential medical equipment is supporting primary health care to the general population. District facilities are numerous and widespread in most developing countries. Maintaining this large volume of basic, essential medical equipment presents a special challenge.

Status of Maintenance in Developing Countries

Large cities in most developing countries now have maintenance workshops, often built on the grounds of major hospitals. Many of these workshops can repair complex medical equipment and offer adequate services to the major hospitals with which they are affiliated. They are fully occupied, however, in coping with the ever increasing numbers and complexity of medical equipment in major hospitals; therefore, their services cannot be easily extended to district health facilities. The growth of maintenance services simply is not keeping pace with the rate of deployment of medical equipment in these countries.

The ministries (or departments) of health in developing countries, often lacking in equipment maintenance expertise, may believe or expect that the few established workshops have the capacity to resolve the equipment maintenance problems of the nation as a whole. In contrast, the technical staff in those workshops, traditionally confined to lower-ranking positions, rarely have the opportunity to develop a national perspective. Their needs and objectives are usually to further their training in order to advance their high-technology skills; these goals are often justified, considering the complex equipment that they service. These conflicting expectations do not lead to an effective solution for the national needs in medical equipment maintenance. What, then, is an appropriate strategy to tackle this problem?

Priority needs to be given to large-scale training of "basic" technicians and the establishment of smaller workshops in the districts to maintain essential medical equipment. This training task will take less time and cost to accomplish as compared with training technicians to maintain complex items or equipment, and it has a number of additional advantages described below. These issues are analyzed with the aid of an empirical model.

An Empirical Model

A country's medical equipment inventory can be represented by the pyramid shown in Figure 38-1 (Cheng, 1993).

In Figure 38-1, height represents, in approximate order, equipment complexity, while width represents equipment quantity. The pyramid shape indicates that simple equipment greatly outnumber complex equipment. For example, there are obviously more weights, scales, stethoscopes, and sterilizers than ultrasounds, lasers, and CT scanners. As the complexity of the devices increases, the numbers available decrease. The bottom half of the pyramid comprising devices such as sterilizers, microscopes, water baths, scales, and stethoscopes can be maintained by technicians with a minimal amount of training and cost.

The maintenance of the wide range of equipment identified in Figure 38-1 requires a correspondingly wide range of technician skill levels, and the cost or time required to train a technician increases dramatically with the level of skills required. This situation is illustrated by the curve (*oc*) in Figure 38-2.

In Figure 38-2, the inventory of equipment is divided into complexity categories A and B; *ob* represents the cost or time to train a basic technician to maintain the simple category B; *ba* represents the cost or time required to train a mid-level technician to maintain category A. This graphical comparison suggests that at a much smaller cost, or in a shorter period of time (*ob* compared with *ba*), technicians can be trained to maintain a larger quantity of basic essential medical equipment (B compared with A). The actual relationship between basic complexity and cost or time (curve *oc* in Figure 38-2) will not be exactly as illustrated, but in general, the idea of a rapid increase of cost or time with com-

plexity is valid. If special attention is given to the maintenance of essential medical equipment in support of primary health care facilities, the population at large can benefit comparatively quickly in many developing countries.

Development and Implementation

Given the current situation in many developing countries, the pyramid model suggests an appropriate strategy to attack the problem of medical equipment maintenance. This strategy calls for a priority in the training of technicians to maintain the relatively simple but plentiful essential medical equipment commonly found in district health facilities. This strategy requires less time, costs less, and delivers benefits to a larger population.

Here lies a happy coincidence in which the easier way of doing things is also more economical and beneficial. The following further advantages can be derived from this strategy:

- Mid-level technical expertise local trainers in existing workshops can be utilized.
- Because of less stringent prerequisites for selection, a larger number of candidates can be recruited for training, enabling a relatively rapid multiplication of technical human resources.
- Because of the large amount of similar equipment in use, it may be possible to carry out apprentice training on the job so that the trainees can provide actual services to health facilities.
- This strategy suits well the market economy that is now found in practically all countries around the world. Complex repairs can be done more cost-effectively by company enterprises. Companies are obliged to have trained technicians to support the equipment they supply. In-house and company services can be used to best advantage.

On the other hand, if the alternative of advanced training for staff of existing workshops is pursued without a larger backup workforce, it is necessary to select candidates who already have mid-level skills and to send them to service schools for training. Because there are usually few such technicians in developing countries, existing services would be interrupted. In some cases, suitable technicians would go from one overseas training program to another, with little time to deliver actual services in the home country. Moreover, upon completion of a training program, some trainees would choose to work for another organization, or to emigrate to a country where prospects of a more lucrative career are better. The loss of highly trained technicians could be devastating to a country that is striving to build up a maintenance service while coping with a shortage of technical personnel.

By initially concentrating on training a large number of technicians to maintain basic, essential medical equipment, a pool of technically skilled people will be made available for services and for higher training. This can provide a more stable base to develop maintenance services further.

No doubt, successful development of medical equipment maintenance services depends on critical factors such as political will, local cultural attitudes (Taylor et al, 1994), and financial support. In several countries that the author has visited, all necessary supports were available, but the development programs were still getting nowhere because actions were not effective in solving the problems. Both the national executing office and the international aid agency were dissatisfied and were searching for a better approach. It was from these countries that the strategy elaborated in this chapter was developed.

The situation in these countries can be likened to that of a ship. Given a captain and crew (i.e., political will and operating support) and fuel (i.e., financial support), the ship can move along. If the captain has no clear direction to steer the ship, however, the ship could be moving around in circles in the middle of an ocean. The strategy presented in this chapter is like giving the captain a direction to steer the ship toward a productive destination. When one loses the way, a compass can provide guidance. When a particular issue is important to a country, a strategy can help to coordinate all national efforts toward a national goal.

The simplicity of the pyramid model can help nontechnical decision makers to grasp better the technicalities of equipment maintenance. Such a strategy would call for clinical

Figure 38-1 Diagrammatic inventory of medical equipment.

engineers in developing countries to acquire management and training skills in order to lead or manage national medical equipment maintenance programs.

Conclusion

Giving a priority to maintaining essential medical equipment to support primary health care facilities has the advantage of meeting the urgent, current needs in many countries. It can decrease the required time to bring benefit to the broader population. Furthermore, this approach can utilize skilled personnel as local trainers in existing workshops to multiply the workforce efficiently. Adequate technical human resources and a network of basic workshops across a country can provide a foundation to create a culture and an infrastructure to facilitate higher development in medical equipment maintenance, thus helping to overcome some chronic obstacles in countries that lack a strong industrial base.

Figure 38-2 Relationship between complexity of equipment and cost and duration of training technicians.

This also can be used as a general strategy to promote cost-effective maintenance for medical equipment in the market economy where private companies would do most specialized repairs while the in-house staff would confront problems on the front line.

Outsourcing Clinical Engineering Service

Peter Smithson

QA & Organizational Development Manager, Principal Clinical Scientist, Medical Equipment Organization, Bristol, England, UK

David Dickey

President & CEO, Medical Technology Management, Inc. Clarkston, MI

Clinical equipment ownership results in a financial liability that extends far beyond the cost of equipment purchasing, installation, testing, and user training. Yet when properly defined and aggressively managed, a consolidated medical equipment service management program can create substantial cost savings for any health care organization, especially given the continued increase in new and replacement high-technology equipment purchases. Considering the fact that many capital acquisitions are of assets that have a useful life of seven or more years (especially when considering the asset's longevity through planned upgrades), it is not uncommon to expect an annual ownership (service) expenditure of 5% to 12% of the equipment's original purchase price, depending upon the mix of equipment modality. Choices as to the best way to provide for a consolidated medical equipment maintenance management program can typically be categorized into two types of program models: (1) in-sourced (in-house) and (2) out-sourced.

Outsourcing

What is out-sourcing? Essentially, it is the transfer of any defined business operation or responsibility to another organization. In terms of clinical engineering, it could involve the transfer of responsibility for selected portions of equipment service, procurement, or program management to an external business entity or organization, all for one agreed upon or "not to exceed" price. It could involve transfer of the financial risk, with or without service staffing, as well. Typically the company providing the outsourced service makes all service decisions and assumes responsibility for all outcomes (i.e., good and bad).

Two Service Models

One key differentiating factor between the two program models of outsource and in-house relates to identification of the financial risk. As is seen in Table 39-1, all programs can be divided into two main categories, depending on who is taking on the program over-budget risk.

It is important to realize, however, that most in-house (in-sourced) clinical engineering programs typically continue to utilize the services of external vendors, as it would be unusual for any single program to have sufficient internal resources to be able to perform 100% of required services. Given the high number of inventoried devices typically contained within a clinical equipment management program, it would not be unusual for the in-house staff to service only 70%–80% of the equipment base, relying on external vendors, with their specialized expertise, to service the remaining items. Therefore an in-house (in-sourced) program still contains some elements of an outsourced program. For purposes of this discussion, an outsourced program is defined as one that is fully provided by non-hospital staff and whose management (the entire service function) is the responsibility of an external provider. Under a fully outsourced program, all staff are on the out-sourced vendor's payroll, and the vendor is fully responsible for all aspects of program management, performance, and financial outcomes. The hospital pays one price to one vendor, who then assumes all responsibility for paying for all subcontractors, staff salaries, parts, supplies, and overhead.

While there are no requirements or regulations stipulating who can (or must) provide repair services on most medical equipment, certain countries and/or individual states may have guidelines relating to service, testing, or calibration of specific device types such as high-energy radiation treatment or mammography systems. In the United Kingdom (UK), the Medical Devices Agency (MDA) has issued guidelines to hospitals and community-based health facilities that state that any servicing organization must maintain a properly trained staff, the correct manuals and tools, access to spare parts approved by the manufacturer, and adequate quality control procedures (MDA, 1988; MDA, 2000). These could apply to in-house as well as outsourced program providers.

Why Outsource?

The reasons why many organizations consider use of an out-sourced program typically include the following:

- Desire to reduce the number of employees who are directly on the hospital payroll. Many organizations have management goals to reduce the total number of employees (full-time equivalents [FTE]) to meet required staffing benchmark levels based on total number of employees per occupied bed.
- Cost savings. Many outsourced programs are sold and justified on the total program cost, which is shown to be less than the actual or estimated cost of the organization's current in-house programs. This is especially true when the majority of the equipment base, such as for a radiology service program, comes from one vendor or manufacturer who has access to parts and labor at their internal cost.
- Access to resources that are not readily available to the organization (e.g., trained staff and parts). Many outsourced programs are provided by equipment manufacturers who have direct access to parts, supplies, and software products directly or indirectly related to the equipment base of the program being outsourced. In addition, most outsourced programs have developed custom policies, procedures, and software systems that can be rapidly installed at a low cost.
- Short-term solution to a problematic in-house program. Many in-house programs are short staffed or have employees with limited expertise and service capabilities. The outsourced vendor may have underutilized staffing resources in the local geographical area who can be assigned full- or part-time to assist in implementing or providing routine support to the organization.
- Reduced internal overhead related to invoice processing. Given the high cost of processing individual purchase orders for parts, supplies, and individual vendor repair services, an outsourced program can have an indirect impact on the hospital's cost if the internal overhead need to process these invoices and related paperwork can be eliminated or reduced.

OEM Full-Service Contracts

One form of outsourcing involves contracting with numerous vendors for defined capped cost services on individual equipment. Contract costs from the OEM have come down over the years and can range from 2% to 12% of the equipment acquisition cost, depending on equipment modality. Service staff provided are typically well trained, and they have access to all of the tools, software diagnostics, and spare parts designed by the OEM for supporting the equipment.

During the sales process, the equipment vendor may offer discounts to its multiyear agreement and may hope that the one-time offer of the discount will persuade the purchaser to sign up. Many multiyear agreements do not have an out clause or have a high cancellation penalty should the purchaser elect to cancel early. Signing a multiyear service agreement with no "out clause" might not be advisable, as it severely limits future cost savings opportunities, especially if the equipment failure rate is determined to be lower than expected. However, if you bought an item that has a high failure rate, locking in a reduced-rate service agreement would have been advisable. Doing an adequate amount of homework on expected failure rates prior to signing the purchase agreement is obviously advisable.

Given the fact that most of today's medical equipment is software driven, OEM vendors have the ability to bundle new software upgrades into their contract pricing, thus making the software upgrades appear to be "no charge." However, not all equipment will need routine software upgrades, and the astute purchaser should consider negotiating a "not to exceed" price for future upgrades, independent of any full-service contract options. While there is nothing inherently wrong with the full-service contract approach, the main concern is that if you sign a multiyear, full-service agreement, you exclude yourself from all options and future cost saving opportunities should the equipment have a low failure rate or should you wish to use an alternate service vendor or to convert to an in-house program.

Table 39-1 Two models for hospital medical technology service

<i>Hospital transfers risk</i>	<i>Hospital carries risk</i>
(outsourced program)	(in-sourced program)
OEM full-service contracts*	OEM T/M**
ISO/OEM asset management***	ISO T/M
Maintenance insurance	In-house self-insured

* OEM—Original Equipment Manufacturer; **T/M—Time and Materials; *** ISO—Independent Service Organization

OEM Asset Management/Multivendor Service Programs

It is difficult to identify exactly when the first OEM advertised multivendor program was marketed, but it seems to have coincided with the onset of “asset management” programs. While most advertisements tried to market these programs as something new, the concept of having a dedicated or shared technical staff who are trained to service a multitude of products has been one of the key features of hospital-based clinical/biomedical engineering programs going back as far as the early 1970s.

What is new for the OEMs is the offering of their ability to have their employees service equipment not manufactured by them, hence “multivendor services.” The interesting twist here is the fact that for years, many OEMs had continued to claim that only they could service their equipment, as it was so complex, requiring parts that only they could supply. Then, almost overnight, they suddenly had the expertise to be able to service anyone’s equipment, regardless of manufacturer or model.

The reality is that the majority of equipment problems do not always require specialized training and can be resolved by a generalist (biomedical or radiology service) engineer who has basic knowledge and experience on modality-based products. When specialized expertise is needed, it is not uncommon for the multivendor service provider to call in their competitor for assistance, paying for the work under a negotiated time and material (T/M) basis.

Total program cost for a consolidated multivendor asset (service) management program typically will be less than the cost of individual service contracts. Customer satisfaction for these types of programs varies by facility, with most problems relating to irregular staffing, increased equipment down time, and lack of value-added services (to support basic biomedical equipment management functions not specifically outlined in the contract agreement). One primary concern relates to the concern over conflict of interest, based on the questioning as to how the on-site multivendor equipment service staff could possibly work as hard on making their competitors equipment work as well as their own?

ISO Maintenance Service Programs

The Independent Service Organization (ISO) has been in the multivendor service business since the early 1960s. It offers a cost-effective alternative to the OEM or total in-house service program. As outsourced maintenance service providers, ISOs have been providing asset management-type services well before the entry of OEMs into this market, and they typically function at a cost that is less than that charged by the OEM provider. One key feature of an ISO program is that it typically does not manufacture or sell any vendor’s equipment, thereby leading to the potential claim that they can truly be unbiased on the issue of equipment-replacement selection. Many of the ISO programs are geographically based, with ability to offer cost-effective services only to a client population within their geographical proximity.

As with an in-house program, the ISO is generally able to service and support a wide range of equipment, but it may lack the specialized training that is necessary to perform extensive troubleshooting and maintenance of complex systems such as newer computerized tomography (CT) and magnetic resonance imaging (MRI) scanners. ISO programs generally call in the OEM vendor for assistance, either on T/M service or under a limited contract to support such systems when needed. A well-trained ISO program should be able to provide first call maintenance services on 60%–75% of the equipment base, with the balance serviced primarily by the OEM.

Over the years, the number of qualified ISO programs has diminished, with many having been bought up by the large OEMs as a means to expedite their entry into the multivendor service market. The main concern over the use of ISO programs is business longevity.

Maintenance Insurance

The concept of maintenance insurance works on the premise that, by bundling together the service contract budgets of multiple items, one can lower the overall program cost by averaging the T/M service cost needs of all items (Tran, 1994). Using actuarial service cost data on multiple types of equipment, the maintenance insurance program establishes an estimate of T/M costs for each item, including preventive maintenance (PM) costs, then adds in an overhead and profit margin. Under the ideal program, the equipment user then continues to call in their previously used OEM for service when needed, then either pays the bill itself and waits for insurance reimbursement or submits the bills directly to the insurance carrier for payment.

Over the years, variations on the insurance program concepts have been implemented, such as:

- Inclusion of a rebate or shared savings component to reward the hospital in working with the insurer to minimize the annual service costs
- Reimbursement to the hospital when allowing their in-house staff to perform a portion of the maintenance (at in-house labor costs of \$35–\$70 per hour instead of paying the OEM rates of \$120–\$230 per hour)
- Provision of a first-dollar versus stop-loss limit-based program

- Provision of on-site clerical and/or technical staff to assist with management of the program, and its paperwork
- An arrangement whereby the insurer pays the service vendor directly
- Multiyear agreements whereby the annual program premium cost increase is capped
- Ability to add and delete individual items via a pro-rata schedule
- Telephone support assistance in locating alternate parts and labor sources

Some programs have restrictions and other program requirements, however, that could limit the maintenance insurance program applicability to many health care organizations, such as:

- The mandate that all equipment items are included in the program rather than allowing the hospital to select the items that are included for coverage
- Selective coverage, or the situation where the insurance carrier drops coverage for a specific item should its maintenance costs greatly exceed the itemized premium
- Timing restrictions, whereby field service reports and invoices must be submitted within a predefined number of days after the work event, or else they will be excluded from coverage
- The requirement that a work event that is predicted to result in a cost that exceeds a predefined limit (e.g., \$5,000 or \$10,000) must be called in to the insurance program for authorization prior to having the work initiated
- The requirement that the insurance program can mandate the source of parts and labor for certain equipment items. Repairs performed by non-authorized sources (usually at a higher cost) may not be covered by the program, even if the equipment owner has determined that their source (in many cases, the OEM) is better able to perform the repair.
- Scheduled preventive-maintenance procedures that take longer than what the insurance carrier has estimated may be excluded from coverage
- If the equipment is scheduled for preventive maintenance, or if a noncritical repair is needed but the equipment is unavailable, the service staff may have to wait for the equipment to become available, which might be billable time from the service vendor, but might not be covered by the insurance program
- Certain glassware components such as X-ray tubes, image intensifiers, gamma camera crystals, ultrasound transducers, and CRT displays might not be covered if they need to be replaced because of poor image quality (rather than catastrophic failure), as the failure might be categorized as a planned-obsolescence replacement rather than a covered maintenance event.
- Because of cash flow limitations, the insurance carrier might elect not to pay the maintenance vendors within previously stated time frames, thus resulting in the service vendor putting the hospital on “credit hold,” meaning that no additional maintenance services will be provided until all owed payments are made.
- Many marketed maintenance insurance programs are not endorsed by regulated insurance carriers. If not held to the same standards as the insurance industry, they could cancel their contract (or drop selected equipment coverage) with the hospital at any time should their profitability targets not be met. Should they go out of business or have cash shortfalls, the hospital could become liable for having the overdue invoices paid, even though they have already paid the maintenance insurance vendor.

Maintenance insurance, when properly selected and used, can be a useful tool for a growing in-house service program, especially if it results in the taking over of service and support of items previously under warranty or OEM full-service agreement where no maintenance cost data were kept or monitored. This transfers the risk of going over budget while the hospital collects maintenance cost data for a year or two, thus allowing the hospital to be in a better position to self-insure their budget. Ideally, maintenance insurance should not be used for a period greater than one year, or two at a maximum. If annual maintenance costs exceed the program premium, the insurance carrier could raise their rates in order to recover their losses.

Larger hospitals (i.e., those with 300 beds or more) may be positioned to self-insure their maintenance budgets, assuming that they have the infrastructure to manage the paperwork and vendor-services aspects of the program. Cost savings by going to a self-insured program typically cost less than the cost of the maintenance insurance program. However, if a maintenance insurance program is desired, be sure that it is underwritten by a regulated insurance carrier that has a high rating. Programs that the provider “self-insures” should be considered with caution! In the UK, official guidelines advise National Health Service users not to use insurance-based schemes, as their experience has shown that the promised savings are not as high as predicted.

Summary

When selecting an outsourced service provider, it is important that all program components be identified in writing and made part of the contractual agreement. Issues related to on-site, dedicated staffing, parts sources, scheduled preventive maintenance, backup support, external OEM vendor assistance, data ownership, reporting, equipment relocations, upgrades, software, test equipment, user training, committee participation, and total budgetary responsibilities also must be clearly defined.

The cost effectiveness and quality impacts of out-sourced clinical engineering programs versus in-house programs have been the subject of much debate, with many organizations having tried both models. One given fact is that a service program that is outsourced to a for-profit company has two masters to serve: The hospital client, and the business entity shareholders. One master wants the lowest cost and the other wants maximum profit margin. The hospital mandates quality and the out-sourcer is obligated to deliver it. The debate over cost-effectiveness and long-term impact on equipment quality continues to make the choice over outsourcing versus in-sourcing a case-by-case determination.

Even with a fully outsourced program, the hospital still holds the ultimate responsibility for the impact of its equipment on patient care outcomes. The outsourcing of the management of the service program does not mean that the hospital will not be held harmless for patient injuries because of malfunctioning equipment. An outsourced program still needs to be audited, monitored, and held to the same standards to which an in-house program would be held.

New Strategic Directions in Acquiring and Outsourcing High-Tech Services by Hospitals and Implications for Clinical Engineering Organizations and ISOs

Donald F. Blumberg

President, D.F. Blumberg & Associates, Inc.
Fort Washington, PA

The growing costs involved in the support of medical electronics and diagnostic imaging technology and other high-technology equipment and systems found in hospitals and health care facilities today require an objective and professional analysis and evaluation in order to understand fully the underlying causes of these rising costs and to provide a logically defined set of options and alternatives for the industry. Hospitals and health care facilities use, and therefore must service and support, a wide variety of high-tech equipment on their premises, including, but not limited to, the following:

- Computers
- Office automation technology
- Telecommunications, including voice and data networks
- Medical diagnostics and instrumentation
- Other medical instrumentation and technology
- Building and infrastructure control systems

In addition, the very nature of the hospital technology base is changing as hospitals acquire outlying professional offices and health care facilities, moving to a geographically dispersed wide area network configuration. (See Figure 40-1.) The introduction of network distributed diagnostics systems, (e.g., picture archiving and communication systems (PACS) is changing service requirements. In essence, full service in hospitals now requires a broad base of technical capabilities, central control and coordination of calls and logistics, and increasing network service and support. Simple service of diagnostics imaging and medical electronics in one building or small campus will no longer suffice.

In broad terms, the general options that are available to hospitals and health care facilities, the end users of medical electronics and other high-technology, for service and support, are as follows:

- To maintain all equipment through an internally organized and operated biomedical engineering and management information system (MIS) support organization
- To outsource all or a portion of these maintenance, repair, and technical support services to the original equipment manufacturer (OEM) or independent third-party maintenance (TPM) organizations
- To expand services offered to other hospitals; in essence, to move in to the provision of third-party maintenance services in an attempt to increase economies of scale

To the extent that all or a portion of maintenance, repair, and related support services is outsourced, the following three options are available for outsourcing:

- The OEMs that are beginning to offer service on an array of different products and technology on a multivendor service basis
- Independent service organizations (ISOs) providing third-party maintenance services for one or several OEMs' products
- A full turnkey or facility manager or site manager to manage and/or service all or a portion of the equipment at the hospital/health care site.

Until recently it has been extremely difficult for the hospital and health care users, the OEMs, and the ISOs to fully understand and make use of these options and alternatives. Recent extensive benchmarking studies by the author and D.F. Blumberg & Associates (DFBA) of the service of both general high-technology equipment used in the hospitals and specific medical electronics technology, as well as research into the size and dimensions of these market opportunities, has enabled an assessment and evaluation of these issues to be made. This information is presented below.

Figure 40-2 Total North American hospital/health care high-tech service market by equipment/service category (in \$ billions).

Market Size and Benchmark Evaluation

The general market for service and support for high-tech equipment in hospitals in North America is quite large (exceeding \$10 billion in 1996) and is growing, as shown in Figure 40-2. This evaluation, based on an extensive survey of over 500 small, medium, and large general and specialized hospitals showed that the largest single specific area of expenditures in hospitals was for the service and support of medical diagnostics and imaging (electronics) equipment.

In order to clearly understand the underlying economic dynamics of high-technology service and support in hospitals, it is of interest to examine key results of a recent study carried out by DFBA, utilizing a variety of sources, to examine existing cost elements and

components of the typical 300–400-bed general hospital located in major metropolitan areas in the United States. The largest single functional component of cost is direct labor and benefits. Other major cost items include direct overhead administration and infrastructure costs; outside material, equipment, and supply purchases; and all other costs. If trends in these costs over the 1992–1994 timeframe are examined, as shown in Figure 40-3, the direct labor costs can be seen to continue to rise along with the incremental costs of maintenance and supply. It is important in this analysis to note that the significant portion of the total costs of high-technology maintenance and support is buried in direct labor, overhead, and other related costs of the hospital. If the internal and external costs of high-tech maintenance and support along with the building infrastructure, environmental technology, and support were to be computed, the costs of this *function* would represent the second largest cost component in hospital operations.

KEY TRENDS IN TOTAL HOSPITAL COSTS FOR TYPICAL 300–400 BED HOSPITAL

KEY FACTORS	YEAR			% CHANGE
	1992	1993	1994	
DIRECT LABOR AND BENEFITS	27.5	29.0	30.9	12.4
DIRECT OVERHEAD, ADMIN., & INFRASTRUCTURE COSTS	2.9	3.0	3.0	3.4
OUTSIDE MATERIAL, EQUIPMENT, & SUPPLY PURCHASES	3.1	3.3	3.4	9.7
TOTAL MAINTENANCE & SUPPORT COST*	17.1	18.3	20.0	18.1
INCREMENTAL MAINTENANCE AND SUPPLY COSTS**	6.3	7.0	8.0	27.0
ALL OTHER COSTS***	3.3	2.9	2.7	-18.2
TOTAL COSTS OF OPERATION	43.1	45.2	48.0	11.4
OPERATING PROFIT	1.2	1.2	2.6	116.7
PROFIT AS A % OF TOTAL REVENUE	2.7%	2.5%	3.5%	29.6

SOURCE: ESTIMATED BY DFBA, BASED ON AHA, OTHER STUDIES AND REPORTS, AND INDEPENDENT DFBA STUDIES AND SERVICES OF HOSPITALS

Figure 40-3 Key trends in total hospital costs for typical 300–400-bed hospital.

This analysis also indicates that the typical medium to large size hospital's operating profit, though small, has been increasing, primarily because of a significant decrease in other support costs and a significant slowing in the rate of growth associated with direct labor and benefits. An analysis of the total costs of high-technology and building infrastructure maintenance and support as compared to the operating profit provides a clear indication of the potential impact of getting increased economies of scale through outsourcing, downsizing, or growing the service business base. In essence, a 10% savings in high-technology and building maintenance and support costs could lead to a doubling of operating profit. This represents a strong incentive for hospital executives, managers, and administrators to look for all paths to improving the efficiency and cost effectiveness of high-technology, infrastructure, support costs and services.

In order to assess and evaluate the subcontract buy, sell, or outsource paradigm for medical electronics and other high-technology service from the hospital (administrator user), OEM, and ISO perspective, it is necessary to accurately benchmark and evaluate the cost, profitability, performance, and prices of these three major classes of service organizations in the industry. Such benchmarking studies to develop industry averages

and company-specific information have recently been done. Probably one of the most important OEM companies, from the perspective of medical electronics and diagnostic imaging service is GE Medical, which is a major player in the medical electronics industry and one that serves as a standard with respect to diagnostic imaging and related medical electronics technology service base. GE Medical has now moved into health technology multivendor equipment service (MVES) and support.

As indicated in Figure 40-4, key benchmark parameters have been estimated for General Electric Medical, the medical technology OEM industry as an average, and typical ISO/TPM organizations for revenue per field engineer, profitability, call response, and repair completion time parameters. Where comparable, performance information with respect to internal biomedical engineering organizations on the average, and for the largest and most efficient internal biomedical engineering organizations, is provided.

Based upon this benchmark data, further analysis and evaluation were made to examine the true cost of support on a per unit basis and levels of performance in order to gain an understanding of both the economics and service-performance capabilities of these different options for a number of specific product examples. The data suggest that while the

Figure 40-4 Benchmark comparisons of alternative medical services organizations.

typical internal biomedical organization is obviously more responsive because it is based on-site, it also can be somewhat more costly than the typical ISO/TPM organization unless it is efficient. The in-house biomedical engineering department can be inefficient because of low density, lack of an effective management system, and lack of strong incentives to improve productivity. It is not at all clear that the more responsive on-site capabilities of the typical biomedical department offset its higher costs. On a cost-response basis the well run ISO/TPM can offer a better solution, from the viewpoint of the user, than can an inefficient in-house service organization.

An in-depth review for CT scanners and most other products, for example, shows that density affects productivity and cost; i.e., the denser the equipment base served, the more efficient the service. Thus in general, the larger service organization supporting a large base will be more efficient and cost-effective as density increases. In examining outsourcing options, the management's desire for high target margins also affects the equation. Typically, ISO/TPMs, for example, are more cost-effective than the OEM organizations for end users, primarily because of the high profit margins charged by the OEMs to offset low product margins and profitability. GE Medical for example shows profitability estimated in the range of 35% to 42% pretax, whereas the ISOs are accepting a lower level of profitability and therefore, offer a lower price option.

The primary reason for the typical small, in-house biomedical engineering organization being somewhat more expensive and less efficient is that its utilization rates are much lower because of lower density. In essence, both the OEMs and ISOs, by servicing a broad array of customers, can keep their service engineers busier and at a higher level of training and skills than can the internal organization, which spreads its service force across only its own internal installed base. Clearly, one way that hospitals could improve this utilization rate would be to either expand into TPM service for other hospitals or to establish an ISO, which could be utilized by a number of hospitals in one chain or by multiple hospitals in a given geographic area as their central source of service. This has been done in the case of Kaiser Permanente Health Services, for example, where one internal biomedical engineering department serves several hospitals. In essence, under this concept an ISO/TPM built from an internal biomedical engineering department may become the accredited service organization for one or more hospital chains or hospital groups on a negotiated price basis. With the high density of the served base, productivity and cost-effectiveness increase.

Change in Competitive Factors Affecting Efficient Use of Service in the Health Care Market

In the past, OEMs have attempted to counter this trend by creating barriers to service competition through the following tactics:

- Withholding required parts
- Withholding or denying access to required diagnostics
- Withholding or denying training or documentation to others who desire to service the equipment
- Withholding or denying software support or service
- Other actions to deny access to needed information, materials, and software or to tie one service to another, thus making it difficult if not impossible for competitive service providers to operate effectively

In the medical field, OEMs engaged in the above practices and had informal understandings that one OEM would not service the equipment of a competing OEM.

These anticompetitive practices recently came under attack. Through antitrust and other legal actions, the right of OEMs to raise such anticompetitive barriers was challenged. The typical general defense by OEMs engaged in these practices is that they are forced to do so in order to maintain product quality. However, in a case involving Etek (a small TPM) against Picker (a large diagnostics imaging OEM), the court found differently. Typical defenses by OEMs in antitrust actions, (e.g., that they could not be monopolistic in the service market when they were not monopolistic in the product market and that the customer's perfect knowledge of the market would predict price escalation) also have been weakened. A decision by the U.S. Supreme Court in the case of *ITS versus Eastman Kodak* (to remand the case for review, and providing a new framework for examining these issues) has begun to erode this defense (Blumberg, 1992; Blumberg and Quinn, 1992). However, the OEM anticompetitive (and potentially monopolistic) practices did lead to the creation of real inefficiencies in the market, particularly in selected segments such as diagnostic imaging and instrumentation.

The author has determined that the effect of these monopolistic or anticompetitive type practices is to generate a surcharge or profit increase of 20%, and in some cases 40%, over a true competitive price. In the area of medical diagnostics and imaging service and support, this amounts to a surcharge to the hospital and health care industry of over \$500 million annually. Thus, increased enforcement of existing antitrust rules and regulations requiring OEMs to be more open and supportive of all service providers could yield savings of over \$1 billion annually to the health care industry. This strong market incentive is beginning to create demand for new MVES offerings to health care.

Emergence of New Competitive Integrated Service Organizations in the Health Care Market

In general, competition in the health care technology service market is somewhat fragmented and narrowly focused (see Figure 40-5). As noted above, traditionally, almost all medical technology OEMs operated under an informal, unstated "gentlemen's agreement" in which they would not service a competitor's equipment and would not sell parts to or support ISOs. These policies, which were not consistent with the general direction

of OEMs in the data processing and office automation industries, tended to erect real or imagined barriers to the entry of integrated and TPM service providers and significantly reduced the service options available to health care organizations.

However, the following two factors recently have caused a major reversal of this situation:

1. A decline in the demand for the purchase of new capital equipment for medical technology, resulting in a significant decrease in revenues and profits associated with product sales by OEMs and great pressure to reduce the service organization size in light of the reduction in the demand for service of the OEMs products. This, in turn, has led several medical technology OEMs—e.g., GE, Picker, Phillips, and Siemens—to cast off the gentlemen's agreement and to move toward providing multivendor service and support of medical electronics technology in general.
2. As indicated above, certain service-based antitrust cases (including the Eastman Kodak case, which was remanded by the U.S. Supreme Court for district-level review, with guidance) have begun to focus on the monopolistic practices of withholding parts, diagnosis, and documentation support, with the allegation that this creates a monopoly. Both the Supreme Court remand and recent Federal Circuit decisions seem to suggest that the manufacturer's position of withholding parts sales from independent service organizations was at increasing risk. In fact, a recent request by Kodak to restrain action requiring Kodak to sell parts to independent service organizations has been overturned. In essence, with the movement of major medical technology OEMs into multivendor service and support, and an increase in the risk of OEMs withholding parts sales from independent service organizations because of antitrust legal action, the industry providing integrated service and support to the health care market has begun to open up.

As indicated in Figure 40-6, several new or existing service organizations have begun a dialogue with hospital administrators to discuss the prospect of full or partial outsourcing of high-technology service and support on a multivendor basis. Existing medical OEMs, such as GE Medical, Picker, Siemens Medical; independent service organizations who have focused on the medical technology field, such as Innoserve Technologies, COHR, and AMSCO; and relatively new service providers from other market segments, such as Olivetti and Marriott, are now beginning to create the infrastructure to support outsourcing by hospital operators.

Key Trends and Factors Affecting Health Care Technology Service and Support Outsourcing

Managed care is the most critical factor affecting health care technology service and support today and is changing virtually every aspect of health care delivery. Under the traditional fee-for-service contract, health care practitioners were prepared to do whatever was necessary to care for and to cure ailments in their patient population. The role of the health care practitioner was to relieve pain and to focus on caring for the needs and requirements of individual patients. Managed care, with its glass ceiling on fees and expenses, has forced the health care community to manage the outcome of the patient population rather than to attend to the needs of the individual patient.

Because of this paradigm shift, health care community is becoming increasingly more cost-conscious and business-minded. The health care community must constantly weigh and balance the alternatives of providing the highest quality of care against the cost of potential outcomes this care provides. While this has a negative effect on suppliers of health care products and services, some vendors have found an increase in sales because they have demonstrated that their products and services improve the bottom line. Other vendors who have not been able to adjust effectively to the new realities of the health care industry have experienced a decrease in sales.

The new reality of health care is that the industry is becoming increasingly more market driven. Health care organizations (HCO) and payers (i.e., insurers) are thinking and acting more and more like major corporations. Their primary focus is on increasing revenue while controlling costs. However, capitated payment plans of insurers severely affect the level of revenue a health care establishment can obtain. As a result, a hospital or a physician's practice can no longer purchase new products and technology and then place the costs on the patient population by raising fees. Today, new equipment can be purchased only if it can help to win new health maintenance organization (HMO) contracts or to improve the productivity and efficiency of health care delivery. As a result, the life of existing equipment is extended, while increasing the utilization of the equipment in order to recover the full cost of ownership. In order to achieve this end, the hospital itself is functioning more like a factory, attempting to increase the number of patients who go through the system, while shortening the length of time the individual patient is in the system. In essence, hospital administrators are concentrating on developing and implementing practices that decrease the cycle time and increase the throughput of the patient population in order to improve efficiency, productivity, and ultimately, the profitability of the HCO.

This market-driven corporate focus has led to a number of new and emerging trends, which have a significant impact on the effects of hospital operations and in turn impact requirements for technology service and support. These trends include the following:

- A movement toward greater consolidation, which results in the creation of economies of scale and reduces the overall size of the purchase opportunity for new equipment, but increases the overall opportunity for services while decreasing the number of potential buyers of service.
- Hospitals acquiring offices of general practitioners and specialists to increase control of the geographic market. As a result, the remote offices and clinics must be integrated with the central hospital campus and combined with a greater emphasis on increasing utilization of the existing facilities and technologies. The technology service organization is no longer responsible for merely equipment within one building or campus, but for that of the entire hospital network. Furthermore, increased utilization of equipment

**CLASSES OF COMPETITION IN THE HEALTHCARE SERVICE MARKET
(BASED ON U.S. MODEL)**

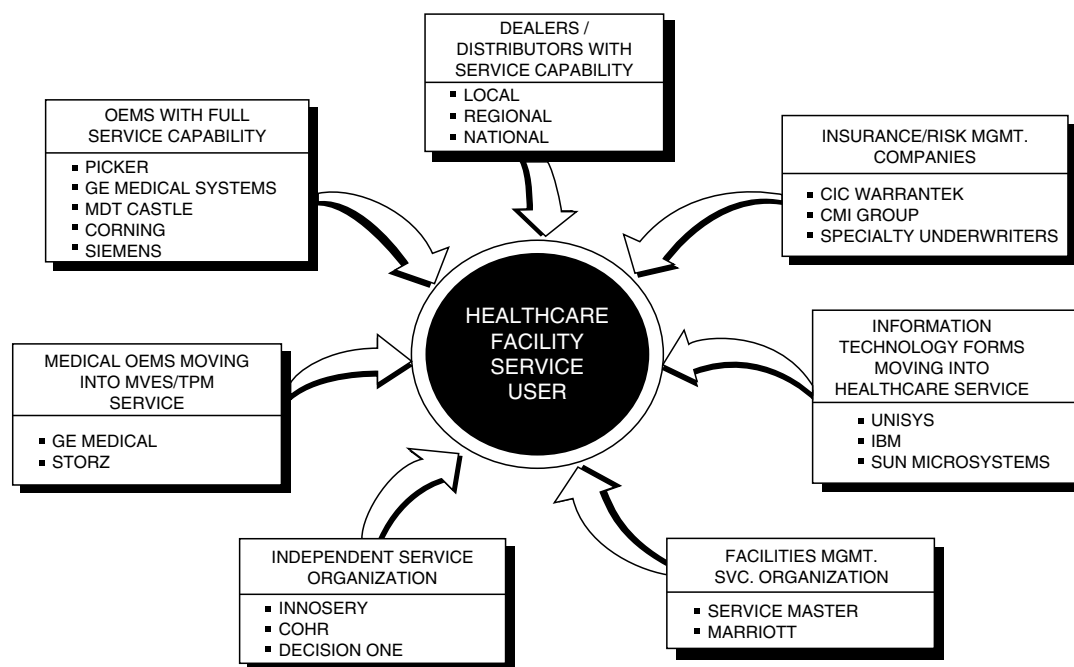

Figure 40-5 Classes of competition in the health care service market based on the United States model.

results in more frequent equipment failure. As a result, service response and repair become highly critical.

- Deployment of advanced networking technology, such as PACS technology, integrates clinical functions such as diagnostic imaging and laboratory analysis into a distributed network that is shared by all facilities and locations that are part of the health care delivery system. (See Chapter 102.) The increased deployment of the network technology results in the requirement of sophisticated network service and support to be available on a distributed basis.
- Increased cost considerations result in the use of a cost control committee and the placement of more purchasing responsibility on the materials managers, thus, increasing the emphasis on equipment and facilities planning (see Chapters 30 and 32) and enhancement of efficient asset management and control (see Chapter 35). As a result, equipment and service purchases are scrutinized for cost efficiency and justification. In addition, equipment and service are purchased on a shared basis for more efficient utilization of capital and operating costs, thus increasing utilization rates, needs for service coverage, and higher equipment up time requirements. (See Chapter 47.)
- Collaboration is more commonplace and results in an increased need for integration and shared reward programs, which leads to a decrease in equipment service purchases and consolidation of service contracts.

In essence, key paradigm shifts in the health care industry infrastructure have had a large impact on the purchase of high-tech equipment and supporting services. On one hand, there is an increased demand for highly reliable equipment and related support services creating a major opportunity to those vendors who can meet the needs and requirements of hospital purchasers. On the other hand, the downward pressure to control costs and to improve operating efficiency has resulted in hospital decision makers placing greater scrutiny on the value and benefits that the acquisition of new equipment and services have on the health care delivery system. The ability of vendors and suppliers to meet these conflicting requirements is a key factor in determining future success in the health care market.

Implications to the Health Care Technology Service Market

The new paradigm shift in health care has resulted in hospitals becoming part of a large corporate organization. The primary motives of the health care organization are no longer medically driven but financially driven, as hospital decision makers behave more and more like corporate executives. Decisions for equipment service purchases are made centrally, at an administrative or executive level. Furthermore, the decision maker focuses on

the requirements of the entire organization rather than those of one department or floor within the hospital. Like most corporations, the chief executive officer of the hospital delegates decision making responsibility through the organization and relies on recommendations from subordinate managers regarding strategic decisions with respect to health care technology service and support. Accordingly, in-house clinical engineers are in a key position to impact and to influence the decisions regarding questions of whether to outsource service or to expand it internally.

In order to make informed decisions on the issue of outsourcing or expanding service internally, clinical engineers now must look at how they are going to meet the service needs and requirements of the entire hospital network. (See Figure 40-1.) The total installed base, which must be managed, includes not only medical devices inside the hospital facility itself but also the devices within doctors' offices and clinics, as well as technology that is shared or integrated between facilities. In essence, the focus of the clinical engineer is no longer on supporting a medical device on a floor of the hospital but on all the facilities that constitute the hospital infrastructure. The clinical engineer is responsible for delivering support on a densely populated, somewhat dispersed, installed base of medical technology. This installed base geography can be as large as a major metropolitan city and thus it can have the characteristics resembling those of a branch office of an OEM or ISO.

In-house clinical engineers must manage this total installed base of technology in the most efficient and effective way possible. (See Chapter 30.) The key issues revolve around providing the necessary support to extend the technology life cycle and providing the necessary service to maintain high end user requirements for service response and repair times. In order to make the optimum decision, the in-house clinical engineer should analyze all components of the service delivery value chain (See Figure 40-7.) This chain can be defined as all activities, tasks, and procedures that are required in order to respond to and to resolve requests for service. The value chain analysis is a new approach, which many clinical engineers are using to manage optimally the entire service operation. The components of the value chain include the following:

- On going and continuous evaluation of service strategy and tactics
- Implementation of this strategy vis-à-vis current service operations, which include:
 - receipt of service request
 - isolation of problem
 - determination of probable causes and symptoms accepting ownership for problem resolution
 - determining corrective action and identifying and utilizing service resources (i.e., parts, skills, and documentation)
 - implementing corrective action and problem resolution
 - updating experience and fine-tuning service strategy tactics

The clinical engineering manager or administrator can improve service efficiencies and costs by placing emphasis on managing one or all of the individual components of the

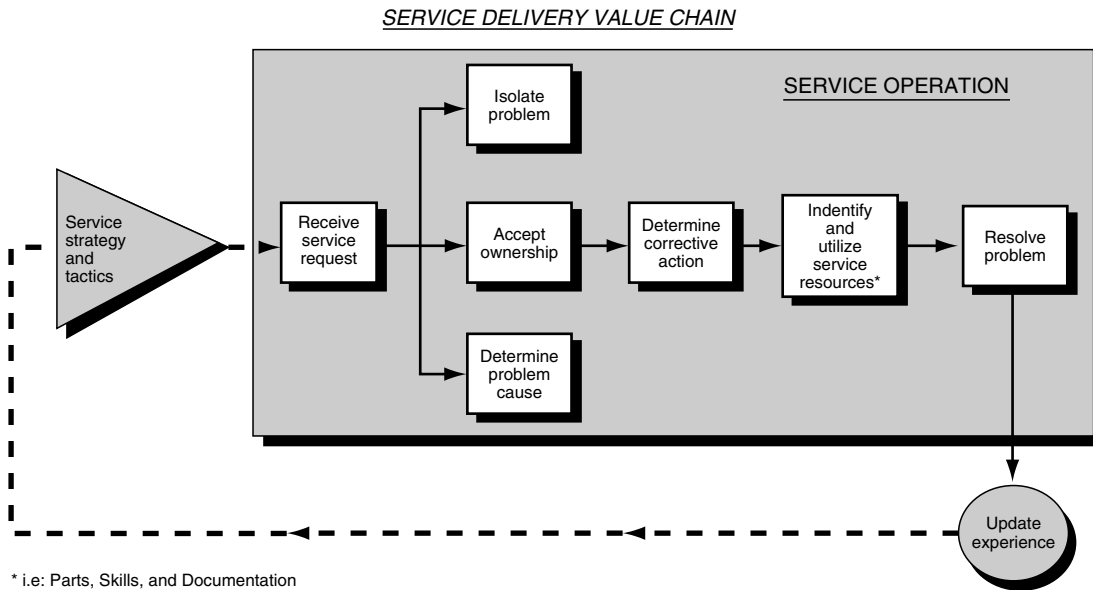

Figure 40-7 Service delivery value chain.

service delivery value chain. In essence, these components can be performed internally or they can be outsourced to an external vendor in order to realize gains in service productivity, quality, and efficiency. By focusing on the value chain, it becomes increasingly clear that there is a high demand for ancillary support services such as remote diagnostics, help desk, and parts management. These ancillary support services enable the manager and administrator to manage optimally the value chain. The focus is no longer on determining how many people will be required in order to support the technology but on

determining the functions and processes that will be required in order to maintain medical devices effectively. From the supplier's perspective, the service delivery value chain creates new opportunities for value-added ancillary support services, which have a high value in use, thus creating new service offering and the potential for unbundling service contracts and offering some services at a premium. The acceptance of the value chain management concept ultimately will result in more opportunities for health care technology service and support.

Current and Emerging Service Requirements of Hospitals

The author has conducted extensive market research to validate and quantify the basic assumptions about health care technology service and support as well as measure the impact of key trends on managing health care technology service and support requirements. Conclusions are based on market research designed to quantify attitudes and perceptions of hospitals, clinical engineers, biomedical equipment technicians (BMETs), and administrators. The research, conducted over a 12-month period (1996-1997), utilized six focus groups comprised of clinical engineers, biomedical equipment technicians (BMETs) and administrators and entailed telephone surveys of 350 small, medium, and large hospitals.

The focus group results confirmed that hospitals are continually exploring the possibility of outsourcing services. Focus group participants believed that managed care had caused, and that it would cause, many hospitals to eliminate their in-house service staffs. In addition, with more hospitals merging, they believed that it made sense to streamline service by either consolidating in-house clinical engineering departments or utilizing an outside service provider. Focus group participants suggested that the culture of a hospital determined whether the hospital would outsource the clinical engineering department or allow that department to grow. A hospital would be less likely to outsource the department if the administration has a high level of confidence in the department manager and has made a commitment to keep the department in-house. However, often because of a lack of knowledge at these administrative levels, the biomedical department can have a substantial influence upon decisions.

Many of the focus group participants indicated that the level of service that they were getting from outside providers did not meet expectations, particularly in the areas of telephone technical assistance and parts availability. To that end, focus group participants indicated that they desired better service from outside providers. Many participants confirmed that their hospitals had a high value in use for specific ancillary support services. For example, focus group participants expressed a willingness to pay a premium if the level of support that they received would help to lower turnaround time, lower costs, and improve quality—particularly those technologies and modalities where in-house support capabilities were limited to nonexistent. This comment fully validated the position that CEs and BMETs are now utilizing ancillary support services to manage effectively the service delivery value chain. Most importantly, these focus group findings confirmed that CEs and BMETs were managing service and support strategically, utilizing outside vendors, and emerging technology to manage the service value chain.

These focus group findings were further substantiated by the results of a second large-scale survey of over 350 decision-makers and hospital organizations. The survey results indicated that the decision making had become more centralized and that hospitals had tight requirements for service quality. (See Figure 40-8.) The most important factors when evaluating service performance appear to be technical knowledge, ability to resolve problems over the telephone, and first time fix right. The cost of maintenance services is less important than service quality-related issues. Survey research has shown that a high percentage of hospitals have an interest in an integrated service contract from a single-source provider. (See Figure 40-9.) In addition, hospitals desire a broad array of ancillary support services (see Figure 40-10) and are willing to pay a premium over and above the basic service contract rate to receive these value-added ancillary support services, which are vital to managing the service delivery value chain.

Strategic Evaluation

In summary, the hospital health care technology service market is large and growing. The American market for health care technology service was \$20 billion in 1996 and is expected to grow to \$41 billion by the year 2001. The hospital market offers some unusual features, which can become the basis for an extremely profitable growth business and service. Much of the growth will come from new ancillary support services, which are generally in demand for health care technology, including network service and support, technology assessments, and telephone technical support hotlines. Furthermore, service requirements are changing dramatically because of a number of key trends of an economic, managerial, and technical nature, including increasing cost-containment pressures, hospitals' desire for control of the total market by acquiring outpatient facilities and doctor's practices, new network technology, and increasing criticality of services.

The health care technology service market can be segmented into two types of organizations: Hospitals without internal biomedical service organization that require basic and value-added services and hospitals with internal service or service management (i.e., total asset management providers). (See Figure 40-11.) These types of organizations still require added-value ancillary support services in order to manage the service delivery value chain, although they do not require basic services. Competition, which is still fragmented because of hospital OEM strategy, is now changing. Of the major classes of competition, the OEMs and ISOs will have the most significant impact because of their ability to offer a fully integrated service portfolio. While there are a number of OEMs with nationwide service organizations, it is clear that the strategic direction of the organization will support two extremely different patterns:

- OEMs expanding services in a strategic line of business and/or expanding their service portfolio
- OEMs moving out of service

The traditional ISOs will consolidate and continue to become more aggressive. Other ISOs in the information technology service market will penetrate the hospital technology service market. The ISO market will continue to grow and expand into more areas of equipment service, and manufacturers will be less of a force in the service of their own equipment.

An emerging class of competition for both the OEMs and ISOs are hospitals forming their own for-profit service companies or shared service organizations. A number of hospital clinical engineering departments are pursuing this strategy in an attempt to expand the service capabilities while combating the threat of outsourcing.

Not only are the market and competition changing rather rapidly in health care, but also new service management systems and technology (Blumberg, 1996) to improve the efficiency, productivity, cost effectiveness and delivery of service are becoming available. These new technologies focus mostly on the optimization of service resource allocation. The new technology is taking a number of forms, including improved service planning and forecasting models, new technology for call analysis, help desk support, technical assistance and call avoidance, new software for optimized scheduling and dispatch, wireless communications, and mechanisms to improve interaction between headquarters call management activity and the service engineering using a laptop or personal digital assistant (PDA). The new technology is enabling service providers to manage the value chain and to generate service quality improvement more efficiently. The technology is becoming a basic requirement for competing in the health care technology service market. However, investment in this technology is significant, making the decision to enter or to expand into service a strategic related question.

Strategic Steps in Determining Optimum Action by Hospitals

It is evident that hospitals and OEMs will continue to consider seriously three possible alternatives for managing the service operation:

- Significantly grow or expand
- Outsource subcontractor or downsize
- Joint venture or divest

This decision is clearly not a simple one. It requires a strategic assessment and evaluation where a number of considerations must be made, including, evaluating the following factors:

- The importance of service to the service organizations' customers and users
- The observed perception of service quality and responsiveness on the part of the market or user community to individual company considering outsourcing
- The current level of service efficiency and productivity as compared to other equivalent service organizations in the market

These key issues will determine whether a service organization will be best advised to make any appropriate strategic changes in order to significantly reduce its costs and to improve flexibility, efficiency, and performance. The basic decision making process is similar to the typical make-or-buy decision in manufacturing. It involves a matrix (Figure 40-12) relating to the critical importance of service and the perceived service image of the service organization versus the current level of service efficiency and productivity, benchmarking against industry standards and patterns. The key decision and recommendation will vary as a function of the interaction of these key parameters.

This decision making process has proven to assist health care service providers to arrive at the optimum decision and solution with respect to cost reduction and efficiency and profitability improvement that may result in a decision to grow the service organization and improve significant economies of scale; outsourcing or subcontracting of key service functions and processes to reduce cost; forming a joint venture partnership or relationship with another service organization to gain both economies and scale; and the ability to sell excess or utilized time for an increase in the direct business base and service portfolio. An in-house clinical engineering department utilizing the same methodology could arrive at one to four possible conclusions:

- Maintain and service all equipment using a facilities-based clinical engineering and MIS service department
- Use a combination of facilities-based service and subcontract service
- Outsource a significant portion of all service requirements to an independent service organization or multivendor equipment supplier, where such organizations are reliable to improve service cost-of-benefits
- Consider creating an independent service organization that would be utilized by one or more hospital chains, by either organizing a new independent biomedical engineering service organization or joint venture merger with one or more OEMs

In summary, hospitals and health care delivery organizations should closely examine their present and emerging service needs, requirements, and costs in order to determine the best way to provide service and support over the next decade. These decisions ultimately will move the health care organization into one of two directions: (1) growth and expansion of their internal service organization or (2) outsourcing and downsizing. In order to meet the emerging needs and requirements of health care organizations, OEMs and ISOs need to assess and to analyze the market needs and requirements, taking into account the full range of technology and the need for quality service levels in light of current perceptions of health care providers.

OVERALL RATING OF IMPORTANCE

Figure 40-8 Overall rating of importance of service vendor selection criteria.

Figure 40-9 Level of interest in a single-source service provider for support of health care technology.

Final Analysis and Evaluation

In summary, as indicated above, hospitals and health care organizations and their clinical engineering departments should seriously consider the following two possibilities:

- Outsource all or a significant portion of their service to ISO/TPMs where such organizations are reliable and can provide cost-effective service. This is particularly valid for small and medium-sized health care organizations where the density is low or highly skilled internal personnel cannot be maintained and supported efficiently.
- Consider creating an ISO that is utilized by one or more hospital chains by either organizing a new independent biomedical engineering service organization created by outsourcing existing biomedical engineering groups into a new, self-supporting service unit or entering into a contract with a national ISO that is willing to offer the

required level of service for the broad array of the installed base at a minimum profit.

Under any circumstances, hospitals and health care organizations should recognize the potential interest in these new options to reduce significantly their health care costs to the ultimate user, the patient. Hospitals and health care facilities that utilize efficient multi-vendor equipment, TPMs, or broad-based clinical engineering service organizations could cut annual costs by 45% or more. Based on a general rule of thumb, the cost of contracted-out maintenance and support of all high-tech medical, information technology, building, and environmental equipment in a typical 300–400-bed hospital is about \$5.5 million. Thus, outsourcing to an efficient ISO/TPM or an efficiently run coordinated biomedical engineering services organization or OEM, providing a fully integrated service portfolio, could produce a net annual savings of \$500,000.

Figure 40-12 Key decision model for use in outsourcing and reducing service costs.

For OEMs and ISOs, the best option would be to develop strategies for significantly increasing the density of the base served. Given the significant technological similarity among medical electronics, computers, office automation, telecommunications, data networks, and building automation (all using microprocessor circuit boards and LAN-type communications), a significant payoff could be realized in terms of reduced costs, improved efficiency, and improved response time by expanding the portfolio of equipment served. Experience also shows that a significant improvement in call-handling efficiency and effectiveness using advanced call diagnostics and call avoidance tools can reduce the number of on-site calls significantly. Improved logistics control to reduce certain calls (e.g., when something is broken because of lack of parts) also will significantly improve productivity.

Summary

Based on extensive benchmarking comparison and market estimates, the issues of make, buy, or outsourcing are neither trivial nor easy to resolve in the health care field. However, based on the different perspectives involved, the following general guidance should apply:

- Hospitals and hospital-based clinical engineering service organizations: Small to medium hospitals should consider outsourcing of service to MVES TPMs and ISOs or OEMs who are willing to service the broader array of technology installed in order to achieve economies of scale, lower total price, and reduced response time (by positioning one or more technicians on site). Large hospitals and hospital chains should consider either outsourcing to a large multi service TPM or an integrated major OEM offering a broad service portfolio or facilities management capability. Larger hospitals and chains should also consider expanding their existing clinical engineering support groups into full TPM/MVES, service to increase their served base density.

- OEMs: OEMs should consider expanding their portfolio of served and supported technology to include a broader range of equipment as found in the new metropolitan hospital complex (Figure 40-1) and increasing use of computerized call management and call avoidance and integrating logistics control to eliminate up to 35%–40% of on-site service calls.
- ISO/TPMs: Independent TPMs should explore partnering, joint venturing, mergers and acquisitions to increase economies of scale and served base density. A critical opportunity for ISOs would be to move into fourth party depot repair to rehabilitate and refurbish older but still useful medical diagnostics and imaging equipment, selling at a significant discount from OEM *new* products, and generating profits from service and support. ISOs should also expand their product support portfolio and increase use of infrastructure and systems for call diagnostics and avoidance and logistics control.

Finally, the government itself could help significantly in reducing costs associated with high-tech service by more aggressively enforcing antitrust laws, particularly with respect to medical diagnostics, imaging, and instrumentation technology service. This alone could reduce health care costs by \$1 billion or more annually.

Vendor and Service Management

Joseph F. Dyro

President, Biomedical Resource Group
Setauket, NY

This chapter describes ways in which the clinical engineer can foster excellent relationships with the medical device vendor and can effectively manage the vendor as service is provided for that device. A good working relationship with manufacturers is necessary to ensure proper after-sales technical support by way of such items as documentation, service, parts supply, upgrades, and recalls. On the other hand, it is wise not to be limited to only one or a very few suppliers nor to become too reliant on the manufacturers. The proper relationship starts at the equipment planning stage and not when service problems first appear. Ways in which the clinical engineer can relate to the vendor (i.e., the original equipment manufacturer [OEM]) at the planning stage will be described. Relationships with OEMs throughout the life of the equipment will be optimal if terms and conditions are clearly delineated at the procurement stage. The way to write an effective purchase agreement containing all the necessary conditions will be presented. Throughout the life cycle of the equipment, the responsibilities of the clinical engineer, such as performing thorough incoming inspection, and the responsibilities of the OEM, such as providing clear and comprehensive service manuals, will be described. If the OEM is to play a major role in equipment service, agreements for this should be arrived at during the procurement stage as part of maintenance planning and implementation. Examples of the OEM's expectations of hospitals and health authorities will be given.

After device acquisition and expiration of the warranty, the hospital must arrange for ongoing service for that device. This chapter will describe ways in which the clinical engineer can manage that service provider, whether that be the original vendor or a third-party service organization. Emphasis will be placed on managing outside service rather than in-house service. A concise review and critique of the different methods available to provide maintenance services to equipment purchased will be presented. The advantages and disadvantages of independent (nonmanufacturer) service organizations (ISOs) will be described. Possible ways to structure a maintenance program will be explored, with consideration given to the role played by the in-house maintenance department. The concept of types and levels of required service will be explored. Maintenance management techniques such as auditing existing agreements, identifying equipment serviced, identifying costs, and identifying services provided will be provided (ASHE, 1988). The way to select the most efficient and cost-effective overall management approach will be described. Suggestions will be made as to the way to communicate with and manage service vendors in order to obtain the best possible service at the lowest possible cost. Evaluation of program options should include, for example, identifying all possible sources of maintenance and evaluating advantages and disadvantages. Various types of service contracts, such as pay-as-you-go arrangements, shared risk and managed maintenance plans, and single contractor for all equipment will be explored. Effective cost control techniques will be presented.

Purchase Agreement Requirements

When procuring medical device technology, the time during which the buyer has the maximum leverage to negotiate the most satisfactory agreement is before the purchase. One's bargaining position is severely weakened after the acquisition. Therefore it behooves the clinical engineer to know what the vendor can supply. This would minimize the overall long-term cost of ownership of the acquired technology. The clinical engineer, as a participant in the technology acquisition process, must ensure that purchasing agreements contain, in writing, the following items, at a minimum:

Documentation: Two copies, including such articles as operation manuals, video tapes, service manuals (with theory of operation, detailed electrical and mechanical schematics, parts lists, and troubleshooting and preventive maintenance guidelines and procedures).

Software updates for the life of the equipment: Updates inform the buyer of the availability of upgrades at a minimum. Negotiations before purchase should strive to obtain these updates free of charge or at a reduced charge. Updates should be accompanied by all pertinent documentation.

Parts available for the life of the equipment: Inevitably, even the most reliable devices will fail at some point, for a variety of reasons including user error, physical abuse, adverse operating conditions, inherent design flaws, and random component failures. The useful life of any technology is extended when repairs can be made with replacement parts. Some of these parts may be proprietary and unavailable from other companies (i.e., "second

source" companies that manufacture and sell parts, usually at substantially lower prices than the OEMs'). As a rule, second sources always should be considered for replacement parts in order to reduce the life cycle cost of the equipment. Not only should the parts be available from the OEM but they also should be readily available (i.e., able to be shipped overnight by any of a number of common carriers). Terms for maximum allowable shipping delays should be established as part of the purchasing agreement. Depending upon the criticality of the equipment, the time for shipment will vary from one day to one week.

Parts on consignment: The OEM should supply critical parts so that repairs can be made without delay, with the hospital paying for these parts when used. Working with the OEM can establish what these critical parts are and the quantities recommended. The inventory of consignment parts will depend upon the number of devices in the system and their critical nature.

Spare parts: For large systems such as physiological monitoring systems, the buyer should insist on acquiring spares. For example, if fifty bedside monitors are purchased, then several spare monitors should be acquired, either through purchase or through a loan agreement. Having a spare monitor to substitute for a failed monitor will ensure same-day remedy and will reduce down time significantly. This lack of critical devices could mean that a bed or an operating room or examination room remains unavailable, resulting in lost revenue for the hospital.

Exchange policy: Inquiries should be made concerning the OEM's policy on exchange of a device that has failed. As discussed above, in the case of large systems with multiple identical devices, spare devices will obviate the need to ship a replacement device. For one-of-a-kind devices of a critical nature, exchanging the item for another in the event of a failure will ensure maximum up time and will reduce the pressure to troubleshoot and to repair a failed device on an emergency basis.

Service reports provided by manufacturer's service representative: The purchasing agreement should stipulate that all interventions by the OEM's service representative be documented and that these reports be given to the hospital, to be kept with the device's service records. Legible service reports should detail the identification of the device serviced (e.g., model, serial number, and equipment control number), the full name of the service personnel, the time necessary for the intervention, the problem addressed, the solution implemented, the parts or subassemblies replaced or repaired, and the reasons for failure. In this way a complete history can be developed and can assist in troubleshooting future failures, or it can serve to document inherent design flaws that cause premature failures.

Warranty: An explicit statement of warranty is necessary. Negotiating with the vendor can result in extended warranties that will reduce the life cycle cost of operation of the technology. The systems, devices, subassemblies, and parts that are covered by any warranty should be explicitly stated, as should the conditions of the warranty. For example, in the event of obvious physical abuse of the equipment, the OEM might be reluctant to exchange or repair a failed device. Determining the contribution of physical abuse to the failure is affected by the conditions under which the device is expected to operate, however. When it is foreseeable that a device would be subjected to shock and vibration (e.g., a pole-mounted infusion pump colliding with a door jam) in the course of a typical hurried emergency application, the OEM should be responsible for the repair or replacement. It is the OEM's responsibility to anticipate extremes of operating conditions in the hospital environment when designing and manufacturing medical devices. Adequate environmental testing in the research and development stages of device manufacture should reflect the conditions that will obtain when the device is actually used.

The warranty period must begin after final acceptance of the device or system by the clinical engineering department. This is particularly important in the case of large installations in which implementation may extend over several months. Not until all systems are in place and are functioning according to previously agreed specifications should the warranty period for the whole system commence. Extending the warranty period for as long as possible is an effective way of reducing total life cycle equipment costs.

Environment: The OEM should supply documentation detailing the environmental requirements for the device, such as operating and storage ranges of temperature and humidity, electrostatic discharge withstand, electromagnetic interference susceptibility, and electromagnetic interference capability.

Facilities: Facilities requirement also should be stated, such as required electrical supply (i.e., voltage, frequency, and power consumption); water or gas pressures and flows; and air quality.

Service training: The buyer should require that hospital-based service personnel be trained in the troubleshooting and repair of the device or system. For large systems such as physiological monitoring systems, it is likely that clinical engineers (CEs) and most biomedical engineering technicians (BMETs) will be involved in service and therefore they all should be trained. On-site training is typically the most cost-effective for the OEM and for the hospital. For one of a kind device, such as an ultrasound imaging unit, it would be more advantageous for the hospital to send at least one (preferably two) CEs or BMETs to the manufacturing facility for service training. All training materials should be given to the trainees so that they, in turn, can serve as resource people for the further training of BMETs within the CE department. Redundancy in service capability is highly desirable.

Negotiations should strive to obtain such training as part of the overall purchase. At this time, commitments for ongoing training should be obtained from the OEM in the case of staff turnover or major upgrades to the original equipment purchased. The level of training should be equivalent to that which the vendor provides to its field service engineers and technicians and other representatives. The hospital should reserve the right to determine the individual who receives training and when such training should occur. The OEM should provide a schedule of available training courses and site locations. Obtaining this training as part of the purchase package will avoid training costs at a later date and will further reduce the life cycle cost of the device.

Specialized test equipment: The identification, cost, availability, and training requirements for specialized test equipment must be stated. The price of acquisition of this equipment at the time of the purchase agreement should be negotiated.

Diagnostic software: The identification, cost, availability, training requirements, and licensing agreements of diagnostic software must be stated. Negotiation is advisable because the cost of diagnostic software can be substantial.

Technical support line: A technical support line must be stipulated, indicating hours of availability and minimum response time to inquiries. Methods for communicating technical support should be ascertained, such as phone, facsimile device, e-mail, on-site presence.

Operator training: Provisions for training the operator of the device must be established in the purchasing agreement. The training schedule must accommodate the work schedules of the operators and must be done as soon as the device or system has been inspected and is readied for deployment or installation. It is preferable to begin training during the course of installation for those large systems that have a lengthy installation period. For such systems, a trainer might need to be present for several weeks during the time of system implementation and available for refresher training at least throughout the warranty period.

Vendor service considerations: The various options for vendor service must be understood. Any offer of service contract should detail the response time guarantees and whether response is on site or whether devices must be returned to the vendor. Costs should be established for service contracts typically to begin after the warranty period is over. If a service contract is the desired route to follow, establishing a price and locking in that price at this time would guarantee that a price quotation after the warranty period does not escalate. The service contract should state at a minimum the number and frequency of PM procedures, up time guarantees, and response time. The CE department might wish to take over all service after the warranty period. Time and materials rates (e.g., standard, overtime, and travel) should be established.

Service technician qualifications: Guaranteed presence of OEM technical support is particularly desirable in the case of a large-scale system. It is not unreasonable to require that a manufacturer's service representative be on site for a year if the system is particularly extensive, if the hospital has adequate physical space to accommodate the representative, and if the OEM and hospital agree that the representative can use the hospital presence as a base of operations for services other systems in the immediate locality. This is particularly helpful for the hospital and the manufacturer, especially in a large metropolitan area with many installed systems in area hospitals.

Incoming Inspections

Final payment must be withheld until all conditions are satisfied. The following is a checklist of items to consider at incoming inspection.

- Check for all items listed on the purchase agreement.
- Check for manuals (service and operators) and other documentation as described above.
- Check for accessories such as cables, probes, and remote controls.
- Check for safety of the device or devices and for safe installation (e.g., adequacy of mounting brackets for overhead lights or wall-mounted monitors). Do not limit incoming inspection to an electrical safety check on the laboratory bench. All features of a device's operation should be verified. Appropriate device operation should be confirmed in the environment in which the device is intended to function. Adverse device interaction from, for example, electromagnetic interference or adverse environmental interaction such as excessive ambient light or noise that could deleteriously affect alarm visualization or auditory perception can be detected at this time.
- Check for proper operation by following the manufacturer's test procedures at a minimum. These may be adapted and incorporated into the CE department's procedures for periodic testing after installation. Many clinical engineering departments have procedures for incoming inspections that are more rigorous than those of some manufacturers. Special attention should be paid to the incoming inspection of technology that is just beginning its life cycle and that is being installed for the first time.
- Ensure that all users are trained by the manufacturer before first use on patients. In some cases, it is sufficient for training to be done by in-house personnel, such as clinical engineering or nursing education.

Only after the above have been done should payment be authorized.

Service Agreements

Provided that they are properly negotiated and carefully monitored, the use of a service agreement (i.e., a service contract) can be an effective and appropriate tool in the ongoing support of medical devices. It is to the vendor's advantage to enter into a service-contract agreement with the hospital. The vendor then would be in a position to have increased hospital exposure and contact with hospital personnel, thus increasing the chance of selling more equipment, upgrades of existing equipment, and recommending replacement of a competitor's equipment that also might be in use. With a regular presence at the hospital, the vendor can enhance customer relations and ensure a future revenue stream.

Service Contract Competition

Medical equipment maintenance is a major industry. In the United States, over \$2 billion is spent on clinical equipment maintenance each year. Manufacturers look to their service divisions for making corporate profits. Many hospitals feel that equipment service is already too expensive, and they look for ways to reduce the cost of this service. As a consequence, support services are under increased scrutiny. All service providers are under increased pressure to deliver services at the best possible price for the hospital. Clinical engineering departments feel this economic pressure and must compete with original equipment manufacturers (OEMs) and independent service organizations (ISOs) for the business of medical equipment service. Equipment is in general becoming more reliable and less likely to fail, and it requires less preventive maintenance. Regulatory bodies, quasi-regulatory organizations, and standards organizations have recognized this increased reliability and have tended to relax requirements and recommendations for maintenance.

Determining the Required Service

The hospital must determine the service or maintenance that is needed on a case-by-case basis. Service comprises the following actions:

- **Corrective maintenance**, usually called repair, returns the device to its original function.
- **Preventive maintenance** is used to prevent failures.
- **Upgrades** typically advance the function of the device.

Maintenance comprises overhauls and refurbishing, corrective maintenance or repair, preventive maintenance, calibration, performance testing, quality assurance, safety testing, visual inspections, and user maintenance.

When assessing service requirements for a particular medical device, the following criteria must be considered:

• Maintenance requirements	• Manufacturer recommendations	• Regulations
• Device history	• Utilization	• Environment
• Device function	• Device risk	• Resources

Rationale for Purchasing a Service Contract

The hospital may be inclined to enter into a service contract under the following conditions:

- The hospital lacks the expertise to provide in-house service.
- The hospital lacks sufficient in-house resources to provide support.
- Users prefer the OEM (common with one-of-a-kind, high-tech devices such as clinical laboratory analyzers, catheterization laboratory units, and ultrasound diagnostic units).
- Support is included or may be required with purchase or lease of the equipment, especially clinical laboratory equipment.
- Product would be more expensive to support with in-house resources after considering the cost of training, travel, and special test equipment.
- The in-house service capability cannot guarantee the equivalent service response, particularly when only one CE or BMET is trained and available for service. Dependency on one person is less desirable than dependency on an entire company.

Types of Providers

Many options are available to the hospital for what provider can supply the above service including the OEM, distributor, third-party, or independent service organization (ISO) and in-house department. The following is a summary of the various organizations that can provide service, along with their respective advantages and disadvantages:

Manufacturer (OEM) Service

Table 41-1 summarizes the main advantages and disadvantages of service contracts offered by the original equipment manufacturer.

Independent Service Organization

There are many independent service organizations, varying sizes, locally, regionally and nationally. The advantages and disadvantages of the ISO are listed in Table 41-2.

Hospital-Based Service Organizations

Service organizations that are hospital-based or in-house are typically the clinical engineering departments. These organizations may be known within the hospital as "biomedical engineering," "medical instrumentation," "medical equipment service," or simply "biomed." Advantages and disadvantages of this service support option are shown in Table 41-3.

Payment/Coverage Options

Service providers (e.g., ISOs or OEMs) offer a wide range of options for service of medical devices. These include full-service agreement (FSA) contracts; limited hours (e.g., 8-5, Monday through Friday); limited service calls; preventive maintenance only; labor or parts only; depot; anticipatory (hospital clinical engineering department screening); and risk sharing.

Full Service Contracts

FSA contracts account for 5%–20% of the equipment-acquisition cost. FSAs may be purchased up front (i.e., capitalized). Long-term contracts are offered. They can be included in a lease or in a disposable (reagent) agreement. Table 41-4 lists the advantages and the disadvantages of a full-service contract.

Hospital Time and Materials

A hospital may chose to “go bare”; that is, not to have any service contracts. When service is needed, the hospital pays for the time and materials that are consumed in effecting a repair. Such services can be obtained from a wide variety of sources including OEM and ISOs. The advantages and disadvantages of time-and-materials coverage are shown in Table 41-5.

Table 41-1 Advantages and disadvantages of the manufacturer service contract

<i>Manufacturer Service Contracts</i>	
<i>Advantages</i>	<i>Disadvantages</i>
Resources (service tools, documentation, parts) Arrangements can be built into the purchase Once on-site fast service	Cost Agreements Coverage limited to manufacturer’s products This is changing Service lock-ins due to technical design or company policy

Table 41-2 Advantages and disadvantages of independent service organizations, service contracts

<i>Independent Service Organizations Service Contracts</i>	
<i>Advantages</i>	<i>Disadvantages</i>
Lower cost May be local May be able to cover multiple brands or device types May be specialists in a niche area	Quality variable Stability Reliability Training and parts resources may be most limited

Table 41-3 Advantages and disadvantages of hospital-based service organizations

<i>Hospital-Based Service Organizations</i>	
<i>Advantages</i>	<i>Disadvantages</i>
Should be lowest cost Fast response; no travel time or cost Mission is the same as the customer’s Might manage all institutional technology	Staff usually are generalists Limited technical support Access to documentation and parts is more limited Might not have skills to “fix” the customer

Table 41-4 Advantages and disadvantages of a full-service contract

<i>Full-Service Contracts</i>	
<i>Advantages</i>	<i>Disadvantages</i>
Fixed cost for good budget control Minimal paperwork; limited management effort after negotiation Perception of preferred customer status On occasion, service personnel are the best trained and most skilled Obviates need for possibly more expensive in-house service support May include free upgrades Complex contract may be difficult to negotiate	Usually the most expensive approach; up-front payment Additional hidden costs Locked in/little flexibility/cannot second source Difficult to quantify service received; little or poor documentation No incentive for users to control repair calls Exclusions: OT, certain parts, limited calls, terms...

Single Service, All Inclusive Contractor

Service agreements made with a single contractor offer the advantages and disadvantages listed in Table 41-6.

Traditional Maintenance Insurance

Maintenance insurance is a scheme for providing service for all hospital equipment at a fixed cost. While it has several advantages, it has disadvantages as well (see Table 41-7).

Managed Risk-Shared Savings

Shared savings programs are structured to differ from maintenance insurance primarily by their offering an incentive to the hospital to employ good maintenance practices. As in all of the other schemes described, this too has both its advantages and disadvantages as shown in Table 41-8.

Service Contract Terms and Conditions

The following is a checklist of terms and conditions to look for in the service contract:

- | | |
|---|---|
| <ul style="list-style-type: none"> ● Cancellation clause ● Payment ● Access to equipment ● Exclusions ● Parts kits/stock | <ul style="list-style-type: none"> ● Guaranteed prorated rebate ● Renewal ● Contract length ● Indemnification ● PM specification |
|---|---|

Table 41-5 Advantages and disadvantages of time and materials coverage

<i>Time and Materials Coverage</i>	
<i>Advantages</i>	<i>Disadvantages</i>
Best documentation Maximum flexibility Information allows management to understand service patterns and to take action; incentives Self-insurance (bank account) helps	Difficult to predict cost—pay as you go High ongoing management—considerable paperwork Vulnerable to vendor practices and the “Big Hit”

Table 41-6 Advantages and disadvantages of single-contractor service agreements

<i>Single-Contractor Service Agreements</i>	
<i>Advantages</i>	<i>Disadvantages</i>
One-stop shopping Good budget control Minimal paperwork and ongoing management	Limited flexibility Many contract exclusions Difficult to address quality issues that occur because of lack of specialization and generalist approach, i.e., “Jack of all trades” Obtaining parts in a timely and cost-effective manner

Table 41-7 Advantages and disadvantages of maintenance insurance

<i>Maintenance Insurance</i>	
<i>Advantages</i>	<i>Disadvantages</i>
Good budget control Good documentation Single contract can cover all clinical (and non-clinical) equipment	Reimbursement cash-flow delays Rejected claims Administrative effort is significant No incentive to control cost

Table 41-8 Managed risk–shared savings programs advantages and disadvantages

<i>Managed Risk–Shared Savings Programs</i>	
<i>Advantages</i>	<i>Disadvantages</i>
Good budget control Incentives for good maintenance practices Single contract Documentation good Flexible	Hospital must buy into program Shared savings returns Operations can be challenging

Negotiating

Everything is negotiable. The following is a summary of the types of items that one should consider as being open to negotiation when entering an equipment purchase or a service contract agreement. One might find it helpful to create one's own contract. A contract addendum can be attached to the equipment purchase contract or the vendor's service contract that all must sign.

- Try to negotiate future service contract pricing at equipment purchase. (This allows for future budgeting, should you choose to sign a service contract after the warranty.)
- Choose payment terms that meet your needs, such as paying up front or in installments.
- Be sure to evaluate different service contract options (e.g., parts only, labor only, or preventive).
- Maintenance, normal business hours, full service.
- Where possible, consider several service contractors (not just the manufacturer).
- Prepare for vendors threatening that you will "have to wait longer for service if you do not have a contract."
- Beware that vendors might try to go directly to the device users in order to try to pressure you to sign a service contract.
- Consider the use of maintenance insurance.
- Examine closely what is included in the contract (for example, parts, hours, consumables, and up time).
- Negotiate your terms and conditions:
 - Vendor service representatives must sign in with clinical engineering upon arrival at the hospital.
 - Service representatives must leave copies of all service reports, including labor hours, travel hours, and parts used.
 - Establish and enforce vendor response times (by telephone and on-site).
- Cancellation clause
- Avoid automatic renewal
- Carefully consider committing to multiyear service agreements

Support Resources to Be Negotiated for In-House Service

The following are support resources that an in-house service organization requires in order to properly provide service to medical devices. During the procurement process, negotiations should result in these items being supplied along with the equipment purchased.

- Theory of operation/schematics
- Parts lists
- Troubleshooting guide
- PM procedures
- Diagnostic software
- Training: live, computer-based, video, or teleconference; on-site or factory
- Training (should be the same as vendor service representatives receive and should be available for the individual specified by the hospital)
- Service tools
- Spare parts
- Technical support assistance

Negotiate to reduce cost of service contracts by utilizing first-response screening and troubleshooting by in-house clinical engineering or other in-house personnel and by entering into a shared risk contract.

Manufacturer Service Information Requirements

When negotiating a service contract, the vendor must produce the following information:

- Call back, on-site response, and repair time
- Labor rate
- Standard, overtime, and travel rates
- Service staff
- Qualifications, location, number
- Contract
- Coverage attributes (e.g., number of PMs, uptime guarantees, cancellation, exceptions)
- Shared risk, insurance, biomedical screening and other creative arrangements

Partnerships with Vendors

A good relationship with the vendor will enhance the cost-effective utilization of the technology acquired. Understanding the company's dynamics and knowing its products and personnel yields more successful assessment activities and improves the overall acquisition process. Good relationships make it easier to resolve safety, installation, reliability, and maintenance problems. After the useful life of the product is over, a maintained good relationship invariably will improve the equipment replacement planning process. For much of the life of the product, the vendor is the primary support resource. Establishing a good relationship is the precursor to establishing a partnership with the vendor, which can benefit the hospital by increasing vendor support during the life of the equipment.

How to Establish Relationships

The clinical engineer begins to build a relationship with the vendor at the beginning of the acquisition process. To do this, the CE must be an active participant in the technology management process; i.e., the CE must be involved at the first stage, which is technology assessment (David and Judd, 1993; Bronzino, 1992). At that stage, the CE should come to know all the vendors of a particular technology and should begin to establish a good rapport with those representatives assigned to the hospital's account.

The representatives will come to regard the CE as a principal player in the acquisition process and will be more responsive to requests for information and could positively influence the course of future negotiations. Be cordial to the manufacturer's representative. Communicate regularly and expect the same behavior in return. Ask the right questions, express your needs, and look for the manufacturer to do the same. Establishing a good relationship will benefit both parties.

Actions to Avoid

The vendor must not be alienated. If possible, one should not limit oneself to a single supplier for all needs in a modality. A single supplier equates to no competition, which in turn means higher prices. When acquiring a large hospital-wide system such as a physiological monitor system, it is best to cultivate relationships with three of the prime contenders. While standardization of devices has many advantages, it carries with it the disadvantage of having only one vendor for the device type. Standardization within units or areas of the hospital (rather than hospital-wide standardization) will permit the acquisition of devices from different manufacturers and will maintain the hospital's competitive edge. Do not reveal all information to the vendor, and (especially) do not indicate that decisions have been made to purchase a vendor's equipment before a formal agreement has been reached, because this will adversely affect the negotiation process.

Manufacturer Relationship

Assessment Stage

During the technology assessment phase, the clinical engineer should learn the companies' strengths and weaknesses and should obtain valid assessment data of the companies' technology.

If the hospital has already decided at this stage to purchase from a single vendor (i.e., sole source) it is particularly important for the CE to know and trust the vendor. In order to interact well with the vendor, it is necessary to communicate with a good scientific background on the technology, participate in clinical trials, and thoroughly analyze the vendor's manufacturing capabilities and field service support.

Acquisition Stage

During the acquisition stage, quotations are submitted in response to a request for proposals (RFP). The manufacturer's response should be based on well-defined needs in the specifications established by the hospital and should not be based on extraneous features (sometimes referred to as "bells and whistles.") The manufacturer should reply to the RFP with accurate and complete responses. If the vendor perceives the possibility of a long-term financial relationship with the hospital, negotiations will be easier and could yield such items as software and hardware upgrades and additional units to retain as replacements in the event of device failure.

A good relationship with the vendor will enable a clearer view of attributes such as manufacturer support resources. The clinical engineer must know the equipment support requirements and the mean time between failures (MTBF). Good relationships promote compliance with requests for service documentation, service tools, diagnostic software, parts, technical support, and direct access to key service personnel and managers.

Service support planning begins prior to purchase. Building a relationship with the vendor early in the acquisition process improves the chances of favorable negotiations.

Vendor Characteristics

The CE and vendor should be comfortable in a give-and-take relationship. Vendors who have the hospital's interest and success in mind are preferable for long-term relationships. Vendors come in all sizes and shapes. Some are good and some are bad. One should cooperate with and help to build up the good ones that exhibit the following characteristics:

<ul style="list-style-type: none"> • Low down time • Respect for the customer • Information provided when requested 	<ul style="list-style-type: none"> • Good technical skills • Good reputation • Few callbacks and problems 	<ul style="list-style-type: none"> • Good communication • Dependability • Quick repairs
--	--	--

Bad vendors have the following characteristics and should be avoided:

<ul style="list-style-type: none"> • No (or inadequate) service documentation • Manufacturer parts only • Noncancelable service contracts • Sole vendor for department 	<ul style="list-style-type: none"> • Remote support only • Will not work with maintenance insurance, third parties, or in-house support • Upgrade requirements for support • Do not return telephone calls
--	--

Techniques for Establishing Vendor Partnerships

The first step in establishing a vendor partnership is to agree that a partnership is in the best interests of the vendor and the hospital where both can achieve financial advantages. A good partnership begins with both parties gaining respect for each other. Good communication skills will foster each understanding the other's needs and the identification of what is to be accomplished through the partnership. When committing to shared success, it is advisable to make outcomes measurable, to establish problem-resolution methods, and to meet commitments.

One should understand that the manufacturer typically needs to earn the profit margin and to obtain the hospital's business. While obtaining the list price is the goal, the better, more flexible, and creative vendors will be willing to negotiate. Be aware that although

service and sales may be separate lines, vendors will be willing to derive less immediate profit from sales in the face of greater profits through a service contract. Some vendors are providing multivendor service, so their interest in service goes beyond the equipment under consideration and includes other hospital equipment that might require a service contract that the vendor can provide.

After the equipment purchase, good manufacturer-CE department communication is needed for planning, coordination, and implementation of the installation, training, incoming inspection and acceptance testing, and ongoing support planning for the operational system.

Several examples of partnerships are illustrated in the following:

Case Study Number One

A rental equipment company partnered with a hospital in the following way: The company established a presence at the hospital. The company owns equipment. It tracks, processes, and charges on the hospital's computer. The company follows the procedures established by the hospital CE department and performs all inspections, preventive maintenance, and repairs; documents work performed; and reports results to the CE director. This scheme benefits both hospital and company. While they both share the risk, they both benefit from administrative and technical service cost savings. Their on-site presence further benefits the patient as it fosters appropriate utilization of the technology.

Case Study Number Two

A major manufacturer of physiological monitoring equipment had an installed base valued at \$2 million in 30 hospitals that are under service contracts to a large, regional clinical engineering shared service organization in the northeastern United States. The equipment had been purchased by the various hospitals over the previous three years. The manufacturer had adopted a new philosophy of outsourcing service in order to reduce its service staff and costly support resources. The manufacturer and the ISO struck an agreement whereby the manufacturer would provide on-site service training for all CE staff and would place parts kits on consignment at the ISO site. The ISO, for its part, charged the manufacturer a reduced rate.

Case Study Number Three

A leading California-based service organization entered into a long-term partnership with a large Vermont-based service organization. The Vermont organization required cost-effective answers to maintenance problems on large, sophisticated, complex imaging and laboratory systems. The California group had the expertise and infrastructure to help them accomplish this and desired an expansion to the eastern United States as well as increased income. The Vermont group was able to continue to provide comprehensive management, sales support, and reporting for the California group.

Managing Service Contract Vendors

Managing service contract vendors and managing one's own in-house clinical engineering department share many similarities. Both entail negotiation, knowledge of services to be provided, monitoring and measuring those services, and analysis and reporting of the results in order to obtain the most cost-effective service.

The goal of any service organization that manages an equipment maintenance program is to provide equally good or better service at a lower cost than that previously or currently provided. The service organization, whether in-house or ISO, must support the hospital's mission; equipment must be available for patient care; service must be cost effective; customers such as physicians, nurses, and administrators must be satisfied; and safety concerns and regulatory requirements must be met. It is typical for one hospital in developing a system of service support to mix a variety of service options such as combining an in-house program with several OEM service agreements.

Centralized Clinical Equipment Maintenance Management

A centralized clinical equipment maintenance management system is recommended for several reasons. Such centralization achieves compliance with standards of the United State Joint Commission on the Accreditation of Health care Organizations and the regulations under the U.S. Food and Drug Administration Safe Medical Devices Act. Typically, over 30% savings over decentralized CE and service contracts are realized. Centralization is a concept that is well understood by bottom-line-oriented administrators who have the perception that equipment service is a commodity.

Over the last decade the trend in hospitals toward outsourcing the service of all clinical and nonclinical technology while maintaining management control gave CE departments (which were in the best position to manage technology) an excellent opportunity to assume this responsibility while achieving significant cost avoidance. CE departments, which already were in synchrony with the hospital's mission, thus added imaging, clinical lab, and other areas to their scope of responsibilities, thus demonstrating that the in-house organization is in the best position for cost avoidance. The utilization of a computerized database system for overall management as well as other administrative and technical tools has enabled on-site service organizations to provide cradle-to-grave management of technology. The success of in-house programs of this sort owes a great deal to the clinical engineers trained as problem solvers and equipped with the skills and knowledge to provide total technology management and service support.

Implementation Basics

The clinical engineer must make key decision makers in the institution aware of the opportunity for cost reduction. To begin, the clinical engineer must perform an audit to determine inventory, expenditures, and coverage. After analyzing the data, the plan should show the changes in operations that will yield improvement in clinical equipment support management. The plan must clearly delineate the mechanisms of monitoring and reporting, the value obtained, the improvements over the current process, the appropriate

service levels for each device in the inventory, the hours of service, the type of services provided (e.g., PM, full-service, or parts only), the response time and completion time, and compliance with regulations and liability issues.

Management Data

The basic rule of management is that one cannot manage what one cannot measure. Therefore, accurate records of such things as time worked, travel time, parts used, and parts costs are essential. An accurate inventory is always the starting point. The maintenance source then must be matched with each item in the inventory. The cost, coverage, exclusions, term, and uptime provisions of all service contracts must be determined. Accounts payable data must be obtained in order to capture expenses for parts, external labor, and other details. All other arrangements, such as leases, must be considered. The result of this analysis is the quantification of in-house costs.

Breakdown of Medical Equipment Maintenance Expenses

A typical management report would include such a graphic as shown in Figure 41-1, the expenditures of the principal users of medical device technology by percent of the total costs.

Several guidelines that will help the clinical engineer to know whether costs are in line with national averages have been developed. For example, the following are estimates of the maintenance costs (\$/bed) for hospitals of various sizes:

0–75 beds = \$1200/bed
76–200 beds = \$1500/bed
201–400 beds = \$2250/bed
>400 beds = \$2800/bed

Cohen (2002) maintains that the best measure of service cost is a percentage of the total technology expenditure acquisition cost. This averages to about 5% for large, U.S. hospitals with CE departments.

Additional factors must be taken into account when managing equipment service, such as customer satisfaction and the quality of service. Such information can be obtained by means of customer surveys. Current service arrangements that have flexibility are targets for additional cost reductions.

Inventory Audit

An inventory audit must be comprehensive and must include all technologies. Data must be obtained for any item that must be managed. Data must be presented in a standardized nomenclature and must include, at a minimum, such items as manufacturer, model, serial number, acquisition cost, location, status and condition of the technology, maintenance provider, type of maintenance (from full-service to electrical safety testing), and a program identification number.

Service Contract Analysis

Service contracts may be obtained for analysis from various areas, including facilities, purchasing, clinical departments, and accounts payable. The type of data should include service provider, term of contract, purchase order, annual cost, type of coverage, special notes, and exclusions and inclusions. Cruz et al. (2002) have developed methodologies for assessing the quality of service of ISOs and for reducing the costs of these services.

Time and Materials Analysis

Accounts payable is typically the source of data about time and materials expenditures. Electronic databases and filing cabinets are the usual repositories of such reports. All items that are not on contract require knowledge of the maintenance account code or vendor code. This process can be time-consuming because one must look at each record to confirm the data. One will find many non-maintenance items such as training, accessories, and rentals. Some expenditures will be missed.

Other In-House Costs

An accurate assessment of the CE department's costs would include cost of personnel, benefits, equipment, operations, space, utilities, advertising, and training. Services should be

Figure 41-1 Expenditures of various clinical departments as a percentage of total hospital cost.

matched to specific devices. Other costs would include such items as maintenance insurance, administrative costs (e.g., the cost to generate a purchase order), and management costs.

Analysis and Proposal

The following are many of the options that are available to the clinical engineer who manages the hospital's medical technology service:

- Review all data and determine the best mix of service providers.
- Eliminate service contracts where possible.
- Change service providers.
- Research ISOs in your locality or region.
- Move service contracts to maintenance insurance.
- Keep items under service contracts or add.
- Critical equipment, service resources not available, proprietary, long-term, cost
- Add and delete items to be maintained.

What is Best Method of Providing Medical device technology Service?

In general, the best option is a mix of in-house service, vendor time and materials, service contracts, and managed maintenance insurance. Annual records of the relative costs of each of the service options selected should be kept. Such data enable analysis in order to determine the optimum mix of service providers.

Monitoring Vendor Performance

Managing service-contract vendors requires the monitoring of vendor performance by such vehicles as auditing of service reports and sign-in logs. Ongoing communication with service representatives is mandatory, especially when devices fail repeatedly. Monitor device-user and service-user satisfaction through surveys and communication. Best vendor service management is obtained when clinical engineering has the authority to sign vendor payments. Contract expiration should be anticipated, as it will provide an opportunity to review the past service in preparation for negotiating a new contract or canceling the old one in favor of another vendor or using the current vendor under a different contract agreement, such as time and materials (cost per hour, plus parts cost). All of this requires keeping accurate records of time worked, travel time, parts used, parts costs, and periodic summaries.

Effective Cost Control Techniques

To effectively control the cost of services provided by any organization, whether it is the OEM or the in-house clinical engineering department, the guidelines listed below should be followed.

Determine the Role of the In-House CE Department

First the CE department must establish that it is the logical choice for managing medical device service contracts and managing the vendors from whom the hospital has purchased medical devices. This starts with an audit of the current activities and resources in CE. Determine the CE department's strengths, weaknesses, obstacles, and threats (SWOT analysis) See Chapter 138 for a discussion of SWOT analysis.

Technical, management, and information systems resources are required along with the ability to form partnerships with vendors. A proposal should be in the form of a business plan (see Chapter 140). The plan should include the following elements:

- Current activities
- Proposed changes
- Investments and return
- Risk-shared contracts/guaranteed costs
- Implementation plan
- Why the CE department is the best choice to manage
- Potential problems with outside vendors
- Ongoing monitoring
- Quality assurance

To gain the hospital's support in obtaining resources, the CE must have a record of quality service, must demonstrate good relationships with clinical and administrative staff and manufacturers, must show value in the acquisition process by defining requirements in the RFP, and must provide valuable decision making information. The CE must define the quality and cost advantages of building CE department support into the purchase.

The CE department should consider an internal contract which defines the requirements for CE and clinical departments, objectives, measurement tools, methods of communication and problem resolution, and reporting costs to user departments. Such a plan will reduce the tendency to point the finger or assign blame for problems and put more attention on patient care.

Cost Control by Vendor Management

The following are various processes and tools for controlling cost by vendor management:

- Service requests
- Who will call vendor? (Department or CE?)
- Logging call: Get all information, open a work order
- Flag high-cost service events and look for options
- Alternate parts, the device worth fixing
- Effect of service on clinical practice
- Reviewing service reports and invoices
- Do not pay for training the vendor's staff
- Parts changes: Only pay for the one that fixes the problem

- Was the problem fixed the first time? Take special note of recurring problem reports or service requests because they indicate that inadequate or incomplete service was performed.
- Timely and accurate submission of insurance claims
- Researching and keeping current on alternative service sources
- Communication with peers to develop new strategies
- Group contracts
- Managing in-house technical staff in their role
- Procedures

Monitoring and Reporting

Service management requires regular monitoring and reporting. The communication process is an effective way to demonstrate the value of clinical engineering and to demonstrate managerial and technical skills. Such indicators as those listed below are typically included in the monitoring and reporting process.

- Cost-based reports
- Budgeted expenses, actual expenses, and variance
- Phase-in of changes
- Additional opportunities
- Quality reports
- Annual or semi-annual customer survey
- Down time or the time taken to return to service

The Maintenance Consultation

In an attempt to establish the value of vendor services, one must be capable of asking good technical questions. Establishment of a friendly relationship with the vendor enhances the flow of information. Questions such as "will the vendor install a hospital-furnished part?" and "is equipment worth fixing?" should be among those posed in the course of attempting to control the cost of vendor service. Vendors might need to be reminded about replacing swapped boards. They also might need to be asked to provide an exchange price for part(s).

Reviewing Service Reports

On occasion, a vendor's service report is poorly written, illegible, inaccurate, missing information, and unsigned by the recipient of the service. Reviews of service reports have revealed duplicate billing; invoices that do not match service reports; inconsistent travel charges; billing for parts not replaced; billing for unnecessary reports; overcharging for parts; tax added on labor; and billing for time on site, inconsistent with the standard time actions performed required. Effective cost control requires that the vendor comply with some basic requirements when completing a service report such as legibility and accuracy.

Reviewing Maintenance Histories (Trends)

The clinical engineer will find ways of reducing costs by reviewing maintenance histories. For example, the need for user training might be indicated when the same problem recurs with atypical frequency. Should problems recur and continue to go unsolved, the clinical engineer should suspect an inherent design fault that even the factory-trained technician is unable to detect. This is cause for requesting warranty credits or a reduction in service charge or replacement under extended warranty of the failing device.

Other Cost-Containment Strategies

Several other cost-containment strategies are listed below:

- Avoid "lock-in" contracts (i.e., those that cannot be canceled without a substantial penalty).
- Perform an end-of-year trend analysis.
- Utilize the proper skill level for the problem.
- Encourage and help the equipment users to help themselves by basic troubleshooting and an understanding of the theory of operation of a device.
- Plan for maintenance at the time of purchase.

Conclusion

This chapter has detailed the essential elements and requirements of a purchase agreement. Incoming inspections have been shown to be a necessary step to ensure that all equipment meets with specified requirements and that authorization can be given to pay the vendor for the delivered product. The various types of service agreements and equipment service providers have been described. The advantages of partnerships with vendors have been presented, along with techniques for fostering those partnerships. The role of the clinical engineer as the appropriate individual to manage service contracts and vendors has been emphasized. The essential elements of an equipment-control program have been reviewed. Finally, effective cost-control techniques have been described.

Health Care Technology Replacement Planning

J. Tobey Clark

Director, Technical Services Program
University of Vermont
Burlington, VT

The health care technology planning process includes assessment of new technologies, acquisition protocols to purchase and introduce effective devices and systems to the hospital, and methodology to objectively and proactively replace equipment. All equipment reaches the point in its life where the cost-benefit ratio goes to the negative because of decreased reliability, increased downtime, safety issues, compromised care, increased operating costs, changing regulations, or simply obsolescence. At that point, replacement must be considered.

Many hospitals respond to health care technology replacement requests with “knee-jerk” reactions, thus causing immediate, unplanned, and unbudgeted replacement of expensive technology. Examples of reactive replacement requests include the following:

- When the device fails at a critical time, even though it might have been reliable in the past
- When the physician returns from a conference and states, “The current technology is obsolete and must be replaced.”
- When the department manager complains, “My equipment never works right” at the capital budget meeting and then “politics” for new equipment
- When undergoing repair, it is found that parts and support are no longer available

Replacement under these conditions can be avoided through a systematic plan to replace equipment in a prioritized fashion (Clark and Forsell, 1990). Health care organizations have limited funding for capital purchases, with many under strict budgeting guidelines. Replacement based on anecdotal and subjective statements and politics creates havoc related to finances, morale, and operations. Clinical engineering departments are impacted if they do not have a replacement plan when major repairs occur in older equipment.

The ideal health care technology replacement planning system would be facility-wide, covering all clinical equipment; would utilize accurate, objective data for analysis; would be flexible enough to incorporate nonequipment factors; and would be futuristic by including strategic planning relating to clinical and marketplace trends and hospital strategic initiatives relating to technology. The plan should encompass many factors relating to cost-benefit analysis, safety, support, standardization, and clinical benefit.

Methodology

Data

One key to developing a robust equipment replacement plan is accurate data for analysis. The equipment inventory is the starting point. A correct listing of the medical device inventory in a hospital is essential. Work orders performed on equipment should reference the unique identifying number in order to track and report on medical device history.

External factors also should be available to help the equipment planning process. Table 42-1 is a comprehensive list of factors to evaluate in determining equipment replacement.

Analysis

An analysis program can be used to interrogate the equipment management database to list a “first pass” listing of items for replacement and scoring. The analysis should cover all clinical equipment on the health care systems inventory. Factors, sample scoring, and weights are shown in Table 42-2. Some are absolute factors calling for urgent replacement, such as serious safety issues or unavailability of parts. Other factors might have formulas associated with the data, which are used to determine whether a threshold has been exceeded. Examples would include the following:

- Maintenance costs over the past three years exceeding 25% of the purchase cost of the device
- Age >125% of AHA equipment life (Arges, 1998) or U.S. Army (U.S. Army, 1992)
- Failure rate outside of one standard deviation for like equipment

Once the first pass list is generated, qualitative factors shown in Column 3 of Table 42-1 would be added to the analysis. Factors including regulatory prohibition or significant cost benefits might call for immediate action. Scoring or adding in these factors requires professional clinical engineering staff making assessments and adjusting the scoring based on their knowledge and communication with administration, clinicians, BMETs, and others. Reduced costs or improved revenues, strong user preferences, and clear clinical advantages are some factors that would put a device or system into a high-priority category for replacement. Various algorithms have been developed for this analysis, some using a simple scoring system and formulas (Fennigkoh, 1992), and others using more complex systems that employ predictive cost, reliability, and parts-availability data and/or analysis (Ridgway, 2002). For the most expensive items (>\$250,000), such as imaging systems, laboratory equipment, and radiation therapy, a life cycle cost (LCC) analysis should be performed to assist with the replacement decision. (See Chapter 30.)

Replacement of an item with a score above the threshold might not be the only option. For some items, an upgrade might solve safety or performance issues, which would allow the hospital to keep the equipment in service. A second option would be the transfer of the device to a less critical application.

The equipment item removed from the department can be disposed, sold to a used-equipment dealer, donated for humanitarian purposes, used in a research lab, or “cannibalized” for parts. Also of note is that not all items removed from service must be replaced. If utilization or need is low, the item might not be replaced, thus saving the hospital the cost of device testing, maintenance, space/utilities utilization, and training.

To be effective, the equipment replacement planning recommendation should prioritize items for replacement into the following categories:

- Urgent—immediate
- Priority 1—next fiscal year
- Priority 2—two fiscal years from current
- Priority 3—three fiscal years from current
- Advisory—product-line changes, published end of support, regulatory (e.g., medical telemetry frequency change)

Communicating Results

The data are best presented in a report showing a facility-wide replacement plan to administration and a separate report used to show a “hit list” for individual departments. The reports should be easy to read and should show inventory item, justification for replacement, and replacement cost. The department report that lists recommended replacement should be presented a month ahead of budget submissions by department heads, to allow review and discussion. It should be clear that the equipment replacement report is a recommendation that provides guidelines and generates discussion and that never should be considered a mandate by clinical engineering.

Once the replacement plan has been finalized, the agreed-upon replacement date should be loaded into the equipment management database to allow proactive actions, should maintenance be required, or should safety issues occur. For example, if an item were listed as being replaced the following fiscal year, a “red flag” would alert BMET staff when a work order was opened that major repairs should not be undertaken.

Conclusion

Equipment replacement planning is an important part of the technology planning process. Immediate benefits include dramatically reducing emergency purchases of replacement equipment and improving the safety and effectiveness of clinical technology. Administration (including finance) and clinicians have a better appreciation of the value of clinical engineering through the objective and rational recommendations made in the equipment replacement report.

Table 42-1 Information requirements for equipment replacement planning

<i>Equipment inventory data</i>	<i>Work order data</i>	<i>External information</i>
<ul style="list-style-type: none"> ● A unique identifying number ● Standardized device type, manufacturer, model, and serial number ● Device risk and function ● Safety features ● Purchase date/age, P.O. number and cost ● Upgrade status (e.g., software and hardware) ● Service provider ● Service/support documentation, tool and software availability ● Equipment replacement schedule based on national data (e.g., AHA or Armed Forces) or depreciation ● Replacement cost ● Manufacturer end-of-support date ● Condition assessment by technical staff 	<ul style="list-style-type: none"> ● Incoming inspection parameters including date accepted, safety and performance values, and pass/fail results ● Failure rate and trends ● Failure type ● Unresolved failures ● Down time ● Costs for parts, labor, contracts, and other work on the equipment ● User problems such as user errors, reports where no problem was found, and abuse ● Recalls, alerts, incidents, and other safety-related information 	<ul style="list-style-type: none"> ● Standards of care for techniques where the technology is utilized ● Technological status: emerging, current, mature, or obsolete ● Utilization data for the equipment ● Standardization in the facility by equipment type ● Reference data and studies documenting cost advantages of replacement of existing technology ● Marketing, competition, and strategic planning information ● Regulatory changes ● Alternative service sources and capabilities ● Vendor data on upgradability and production ● Backup equipment availability

Table 42-2 Analysis of replacement factors

<i>Factor</i>	<i>Scoring</i>	<i>Weight</i>
Age	>125% AHA life = 1 Depreciated = 1	Low
Risk/function	Life support/critical/income producing Non-critical	Medium
Support status	Ended/will end = 1 (unless reliable alternative exists or spare parts)	Absolute (date of end of support = year for replacement)
Condition assessment by BMET staff	Fair = .5 Poor = 1	Medium
Safety issues	Unresolved safety issues = 1	Absolute
Failures	# Events > mean plus standard deviation = 1 Unresolved failures = 1	Medium High
Down time	>10% = 1	Medium
Maintenance costs	>25% of purchase cost over past 3 years = 1	Medium
User problems	# Events > mean plus standard deviation = 1	Medium
Recalls and alerts	# Recalls/alerts > mean plus standard deviation = .5 Unresolved safety problems = 1	High
Standard of care	Does not meet = 1	High
Technological status	Obsolete = 1 Mature = .5	Medium
Utilization	Little or low utilization = -1	Medium
Standardization	Does not conform to standard/cost savings available = 1	Medium
Cost savings/revenue increase	Both = 2 One factor = 1	High
Regulatory	Does not meet regulations = 1	Absolute (date of regulation = year for replacement)
Product status	No longer made/no upgrades available = 1	Low
Backup equipment	Sufficient backup equipment available = -1	Low

Donation of Medical Device Technologies

Joseph F. Dyro

President, Biomedical Resource Group
Setauket, NY

Most charitable organizations donate medical equipment that is unsuitable for its intended use (ECRI, 1992). Most recipients receive donated medical equipment that is functional, meets standards for the institution. Donors fail to ensure that donated equipment is functional, meets standards of safety and performance, has adequate spare parts and accessories available, and is the type of technology that the recipient wants, needs, and is able to operate and support. Most recipients do not adequately describe their medical requirements, available financial support, facilities preparation, or available utilities. By following checklists that accompany guidelines for donation and receipt of medical equipment, substantial waste and inefficiencies can be eliminated. Guidelines for the donation of medical equipment are described in this chapter. The American College of Clinical Engineering (ACCE), the World Health Organization (WHO), and several other health care organizations have been leaders in the development of donation guidelines (ACCE, 1995; WHO, 1997; FAKT, 1994).

The Current State of Medical Equipment Donation

Rationale for Donations

For decades, developed countries have donated used medical equipment to less-developed countries. This recycling of goods accomplishes several important objectives. In developed countries, it helps to keep hospital corridors clear of obsolete equipment and reduces the amount of waste that ordinarily would go to landfills. Frequent equipment turnover also increases the rate of introduction of new technologies. Not insignificantly, donations give a benefactor a good feeling and a belief that that needy people in some faraway country are being helped. Financial advantage through tax deductions also contributes to a donor's sense of well-being. In developing countries, physicians gain quicker access to sophisticated technologies and, most importantly, less-privileged patients gain wider access to better health care (Muschlitz, 1996). In some countries, nearly 80% of health care equipment is funded by international donors or foreign governments (WHO, 1987).

Rationale for Guidelines: Frequently Encountered Problems

Unfortunately, not all donations achieve their goals. Much donated equipment is not or cannot be used by the recipients. It is estimated that as much as one-third of all donations do not achieve their eventual goals, wasting precious time and resources. In Sub-Saharan Africa, up to 70% of equipment lies idle due to mismanagement of the technology acquisition process, lack of user training, and lack of effective technical support (Bloom and Temple-Bird, 1990). Many factors contribute to this reality. Some donors are so anxious to get rid of their unwanted hardware that they pay little attention to the equipment's condition, availability of parts, documentation, supplies, and operator training in the recipient country. In a typical hospital's obsolete equipment storage area, only one in ten devices might be functional. Perhaps more ominously, in some cases, donated equipment has been recalled in the donor country by the medical device regulatory body of that country. Some international relief organizations are forced to concentrate on volume rather than on the quality of donated goods in order to gain publicity and to please corporate donors.

On the other side, many recipients do not carefully screen what they ask for nor invest enough time and resources to plan and support what they get. Sometimes they are spoiled by the notion that they always can ask for another one and can discard what they do not want or failed to maintain. Finally, the lack of communication between the donor and recipients before the shipment of goods is probably the single most important reason why many donations do not work out well.

In most cases, donations circumvent the selection and procurement systems of the recipient country, where such systems exist. As a result, little consideration is taken of actual local requirements, the number of user staff and their capability, and the level of technical expertise of available maintenance personnel. Further problems relating to equipment calibration and operation, purchase of consumables, and availability of spare parts can transform the donated equipment into a liability rather than an asset to the recipient institution.

Some used equipment is repaired or refurbished before it is donated. Care must be taken, however, and it must be realized that beauty often is only skin-deep (Wang, 1996). Figure 43-1 shows what is called the "Spray and Pray" refurbishing method of painting a device to make it look new without doing adequate maintenance or repair of the item.

Guideline Development

First Efforts

Over the last decade, many organizations in industrialized and developing countries developed guidelines on equipment donations. Some of these are listed below:

- Christian Medical Association of India (CMAI): *Study Report on Medical Equipment and Supplies and the Role of CMAI* (1989).
- International Medical Device Group (IMDG): *Policy Position on Donating and Selling Medical Equipment* (1992).
- Association for Appropriate Technology (FAKT), Germany, and Churches' Action for Health (CMC) of the World Council of Churches: *Guidelines on Medical Equipment Donations* (1994).
- Ministry of Health of Tanzania: *Guidelines on Donations of Drugs and Medical Equipment to the Health Sector* (1995).

The above guidelines and other similar efforts, although addressing the same problem, treated it from different angles, going into varying degree of detail, focusing on different levels (i.e., national or international), and targeting different audiences (i.e., donors or recipients, governments or non-governmental organizations (NGOs)). Hence there was a common concern expressed on numerous occasions over the fragmentation of efforts, lack of uniformity and comprehensiveness in presenting the issue, and unmet need of developing countries to have a managerial tool to properly address donations getting the maximum benefit from them (PAHO, 1997).

In 1995, the American College of Clinical Engineering (ACCE) published the first comprehensive managerial tool to aid in the donation process: *Guidelines for Medical Equipment Donation* (ACCE, 1995). Drawing largely upon the work of ACCE, the World Health Organization (WHO), in collaboration with several other organizations listed below, drafted guidelines: *Guidelines for Health Care Equipment Donations, 4th Draft* (WHO, 1997), which include additional management tools.

American College of Clinical Engineering

In 1993, the American College of Clinical Engineering formed a committee to discuss and to find means to improve the effectiveness of donations of medical equipment. The committee members, all of whom had significant international experience, were: Alfred G. Jakniunas, Chairman; Joseph F. Dyro, Ph.D., CCE; David Harrington, CCE; Thomas Judd, ME, CCE; Denver Lodge, ME, CBET, CCE; Robert Morris, CCE; and Binseng Wang, Sc.D., CCE.

By adopting these guidelines, donor and recipient organizations can expect to realize the following benefits:

Figure 43-1 Spray and Pray refurbishing method.

- Better matching of need and availability
- Improved pre-donation planning and preparation
- Assurance of completeness and quality of donated goods
- High likelihood that received equipment will be installed and used
- Assurance of maintainability of donated equipment
- Continuous quality improvement through follow-up evaluations

These guidelines, described below in detail, are divided into five sections. The first section, "Suitability for Donation," helps the potential donor to screen out equipment that should not be made available for donation. The second section, "Evaluation of Potential Recipients," is designed to help the donor to find the right recipient through a careful evaluation of the recipient's clinical need and its resources for operating and maintaining the donated equipment. The third section, "Pre-Donation Planning," helps the donor and the recipient to plan and prepare for the donation. The fourth section, "Donation Implementation," provides reminders for ensuring a successful transfer of goods, including assembly, packaging, shipping, documentation, customs clearance, unpacking, and installation. The fifth and final section, "Follow-Up Evaluation," is devoted to an evaluation of the each donation so that both parties can learn how to avoid past mistakes and how to improve future transactions.

These guidelines are focused only on medical equipment and do not address other medical devices such as disposables, *in-vitro* diagnostic kits, or reusable accessories. As special precautions are needed in handling those devices, potential donors and recipients should seek expert advice from clinical staff or manufacturers.

World Health Organization

The World Health Organization, under the leadership of Dr. Andrei Issakov, reviewed its field experience, existing guidelines, and related documents to develop a globally acceptable document that is flexible and adaptable to a variety of country situations and conditions (Issakov, 1994). The document is a result and culmination of joint efforts of several international and national organizations and individuals who are concerned with problems of health care equipment management in general and health care equipment donations in particular. Collaborating with WHO were the following organizations:

- African Federation for Technology in Health Care (AFTH)
- American College of Clinical Engineering (ACCE), USA
- Association for Appropriate Technology (FAKT), Germany
- Centre for Health Technology, Cameroon
- Churches' Action for Health (CMC), World Council of Churches
- International Medical Device Group (IMDG)
- Medical Research Council (MRC), South Africa
- Technical Cooperation Agency (GTZ), Germany

WHO propounds the following core principles for equipment donations:

- Health care equipment donations should benefit the recipient to the maximum extent possible. This implies that all donations should be based on an expressed and validated need and that unsolicited donations are to be discouraged.
- A donation should be given with full respect for the wishes of the recipient and their authority within the health system and should be supportive of existing health policies and administrative arrangements.
- There should be no double standards in quality: If the quality of an item is unacceptable in the donor country, it is also unacceptable as a donation.
- There should be effective communication between the donor, the recipient authority, and whenever possible the end user before, during, and after the donation.

Suitability for Donation

This section on suitability for donation and the following sections comprise a description of the donation process, taken directly from the ACCE guidelines.

Prior to making equipment available for donation it is crucial that the potential donor make a critical evaluation of it. It is not only a waste of precious resources to move useless and unsafe equipment from one place to another, it also undermines the good will and trust that everyone is trying to build.

General Quality

The donor should ensure that donated medical equipment is fully operational at the system and subsystem levels. All essential accessories and supplies should be available. The donor should follow a checklist to ensure that all subsystems, components, accessories, and supplies (for initial operations) are included, and they should supply the recipient with such a checklist. (Checklists are often found in manufacturers operating manuals and can be prepared by the former operators.) Documentation, especially operating and service manuals with part lists, is critical to the eventual usability of the donated equipment.

Safety, Specifications, and Standards

All medical equipment should meet or exceed existing safety and performance specifications provided by the manufacturer. In addition, they should meet standards promulgated by the American National Standards Institute (ANSI), Association for the Advancement of Medical Instrumentation (AAMI), National Fire Protection Association (NFPA), Underwriters Laboratories (UL), Canadian Standards Association (CSA), or international bodies such as International Standards Organization (ISO) and International Electrotechnical Commission (IEC). Equipment that has not been approved

by the United States Food and Drug Administration (FDA) Center for Devices and Radiological Health requires special export licenses. Equipment that is subject to FDA or manufacturer recalls or hazard alerts should not be donated. Equipment that has nonfunctional subsystems can be donated, provided that those subsystems are clearly identified and labeled.

Obsolescence

A minimum of two years of manufacturer's sales and technical support should be available. This support should include repair parts; accessories (either reusable or disposable); and troubleshooting, repair, and maintenance assistance. Obsolete equipment or equipment for which replacement parts are unavailable should be shipped only if they are designated for parts only.

Appropriate Technology

In considering the provision of medical equipment to developing countries, potential donors should favor the following desirable characteristics in such equipment:

- Simplicity of operation
- Minimal number of accessories required
- Availability of necessary operating supplies (particularly disposable) in the recipient country
- Standardization with other equipment in the locale
- Ease of maintenance
- Tolerance to hostile environment

Evaluation of Potential Recipients

The most important prerequisites for a successful donation are that the potential recipient truly needs the equipment being requested and that it has the means to operate and provide maintenance for it. Although equipment supplied may be completely functional, it will be ineffective if it is not appropriate for the services provided at the recipient site and if it cannot be financially supported through its remaining life cycle. Previous recipient experience with donations is a plus but not essential for the success of the operation. Figure 43-2 is a form and Figure 43-3 is a checklist to assist potential donors and recipients in addressing the issues discussed below.

Clinical Need

To properly justify the need for the goods being requested, the donor should demand from the potential recipient(s) the following information: Which, and how many procedures, will be performed using the requested equipment; why the resources currently available (attach a list with descriptions) are not satisfactory; and an analysis on how the requested equipment will help meet the expected clinical demand.

Readiness to Absorb the Technology

The recipient should be required to provide information showing that it is ready to use and maintain the equipment being requested. Such readiness includes trained operators, appropriate environment, ancillary equipment, maintenance capability, and financial viability. It is acceptable that the recipient demonstrates that it has plans and means to address any shortcomings.

Human Resources

The recipient must employ properly trained physicians, nurses, and/or technicians who will be operating the requested equipment. If none is available currently, an explanation of the way the training is going to be achieved is required.

Environment

The recipient should describe available facilities such as physical space, electrical and pneumatic power, heating, ventilation, and air conditioning (HVAC) to install and operate the requested equipment. Particular care should be devoted to the availability of a stable electrical supply, air conditioning, and humidity control, which are vital to the performance of sophisticated medical equipment.

Material Resources

If the donated equipment is not accompanied by required ancillary equipment, the availability or means to acquire the latter should be described. The availability of supplies that are needed to operate the equipment locally must be researched and confirmed.

Maintenance Resources

The recipient should describe human, material, and financial resources that are available to service and to maintain the requested equipment within its institution. Information about service available from local manufacturer representatives and independent service organizations also should be included.

Financial Feasibility

The recipient must demonstrate that it has the financial ability to install, operate, and maintain the requested equipment.

MEDICAL EQUIPMENT DONATION REQUEST FORM

Note: Fill a form for each TYPE of equipment requested even when several units are needed. Attach sheets with more additional information if there is not enough space on this form.

1. REQUESTER IDENTIFICATION

- NAME OF THE INSTITUTION:
- NAME OF THE DEPARTMENT:
- STREET ADDRESS:
- CITY, STATE:
- COUNTRY, POSTAL CODE:
- PHONE & FAX NUMBERS:
- CONTACT PERSON & TITLE:
- DATE & SIGNATURE:

2. EQUIPMENT IDENTIFICATION

- EQUIPMENT NAME:
- IMDC CODE (ECRI):
- CLINICAL APPLICATION (S):
- QUANTITY REQUESTED:
- SAMPLE BRANDS AND MODELS:
- ACCESSORIES NEEDED:

3. REQUEST JUSTIFICATION

- 3.1 Procedure(s) that will be performed using the requested equipment, with estimated number per month:
- 3.2 Explain why the resources (equipment, methods, procedures, etc.) presently available are not satisfactory:
- 3.3 When equipment is being requested to complement or replace existing equipment or services, please describe the resources presently available:
- 3.4 Compare the expected demand and the production capacity of the equipment being requested:

4. READINESS TO ABSORB THE TECHNOLOGY

- 4.1 Human resources available (indicate additional training if necessary)
- 4.2 Material resources (additional equipment and devices needed)
- 4.3 Space and special installation available or planned
- 4.4 Maintenance requirements (in-house service, external contracts, etc.)
- 4.5 Financial considerations (for installation, operation and maintenance)

Figure 43-2 Medical equipment donation request form.

MEDICAL EQUIPMENT DONATION ACTION CHECKLIST

Donation Implementation <ul style="list-style-type: none"> • Assembly, Packaging, and Shipment • Customs Clearance, Unpacking, Installation, and Maintenance 	Donor's responsibility	Recipient's responsibility
Follow-Up Evaluation	Analyze process and improve procedure	Provide feedback to donor

Figure 43-3 Medical equipment donation action checklist.

Pre-Donation Planning

Assuming that the donor is reasonably convinced that the potential recipient really needs the equipment and can support it for the remainder of its useful life, the two parties should start planning for the donation. First, the donor must provide the recipient with detailed information regarding the installation, operation, and maintenance of the equipment. This information will enable the recipient to begin pre-installation tasks, including the training of personnel for operation and maintenance. In a few extreme cases, the recipient may cancel the donation after realizing that it cannot support the equipment. After all requirements have been satisfied, the recipient will notify the donor to assemble and package the equipment for shipping.

Installation, Operation, and Maintenance Requirements

Installation Requirements

The donor should specify the installation location, accessibility, floor-loading capacity, space and power requirements (i.e., voltage, frequency, phase, and power consumption) and environmental conditions. Care should be taken to identify any unusual extremes of temperature, humidity, dust, and power fluctuations that could adversely affect the equipment's operation. If available, the donor should ensure that detailed installation instructions are provided. Most if not all of this information is available in the equipment's operating or service manual.

Operation Requirement

The donor should inform the recipient of all the necessary subsystems such as cables, reagents, filters, electrodes, and recording paper that will be required in order to operate the equipment to be donated. Test equipment and calibration standards often are required to ensure performance and accuracy of the equipment. Availability of these items throughout the remaining useful life of the equipment should be ascertained. Again, any required operator training should be stated clearly.

Maintenance Requirement

The donor should seek guidance from its own service personnel so it can provide detailed maintenance requirements such as technician training, special tools, preventive maintenance frequency and materials, and test and calibration equipment needed.

Special Requirements

Any special requirements should be identified and communicated to the recipient. These include air or water cooling; electrical power; water quality; mechanical, layout or radiation or acoustic shielding requirements. Specialized software may be required to install, operate, or maintain equipment.

Pre-Donation Recipient Preparations

Assuming that the donor is reasonably convinced that the potential recipient really needs the equipment and can support it for the remainder of its useful life, the two parties should start planning for the donation. First, the donor must provide to the recipient detailed information regarding the installation, operation, and maintenance of the equipment. This information will enable the recipient to begin pre-installation tasks, including the training of personnel for operation and maintenance. In a few extreme cases, the recipient may cancel the donation after realizing that it cannot support the equipment. After all requirements have been satisfied, the recipient will notify the donor to assemble and package the equipment for shipping.

Implementation and Evaluation

Assembly, Packaging, and Shipment

Prior to packaging the equipment to be donated, the donor should ensure that it is safe and performing within manufacturer's specifications. This can be accomplished by performing an operational verification procedure that is found in most operating manuals. In addition, all accessories and supplies should also be checked. All software that is necessary for equipment operation should be included. Training aids such as slides, books, and videotapes should be supplied if available. The checklist (Figure 43-3) should be used to verify that all subsystems, components, and accessories and supplies are included. This checklist also will be helpful in the preparation of the shipping documents.

Equipment that may contain patient material should be properly decontaminated prior to packaging and shipment. Radioactive sources should be removed and properly packaged in special shipment containers (with radioactive marking on the outside). Fluids should be drained and fragile parts packaged with great care. International shipments are often handled roughly by people who lack the proper training and equipment, and therefore they are subject to a high probability of damage.

All equipment should be shipped with operation and service manuals. Software version numbers and significant hardware updates, if applicable, should be noted. The operation manual should contain detailed operating instructions and should list all necessary subsystems, accessories, user-replaceable parts, reagents, and other supplies such as chart paper, gases, coolants, and chemicals. The service manual should contain specifications, schematics, operating instructions, troubleshooting, repair and maintenance procedures, cleaning and/or sterilization recommendations, and a replacement parts list. The supplier

should provide, if available, procedures or recommendations for periodic inspection, maintenance, and calibration to ensure that the equipment is maintained in a safe and effective operating condition. If the documentation is not available, the donor should consider purchasing it to ensure the eventual usability of the donated equipment.

Donated equipment should be packaged in accordance with the method of shipment to minimize damage in transit. For surface shipment, waterproof wrapping and wooden crates are necessary. Air shipment requires less sturdy packaging, but limitations in size and weight are more severe.

Shipping documents should list everything inside the respective packages and should clearly indicate that the shipment is a donation. Sample shipper's export declaration forms and instructions can be obtained from the Department of Commerce through the Bureau of Census, Washington, DC 20233.

Donors who are not familiar with packaging, shipping, and documentation might consider seeking the assistance of freight forwarders and companies that specialize in assisting exporters in transferring goods to other countries.

Customs Clearance, Unpacking, and Installation

Customs clearance is the sole responsibility of the recipient. If special documentation is needed, the recipient should request it prior to the shipment.

The recipient should inspect all containers and contents for damage and should verify that the contents are intact and that nothing is missing. Any irregularities should be reported immediately to the donor and to the shipping company for insurance claims. The manuals received with the equipment should be distributed to the appropriate personnel: Operating manual to the operator and service manual to the clinical engineer or biomedical technician. If a centralized library exists, the manuals should be forwarded to that location.

Installation should be performed according to the instructions received from the donor. After the installation, verification of proper and safe operation must be performed prior to clinical use.

After verifying that the equipment received is working properly, the recipient should implement a program of periodic inspection, maintenance, and calibration to ensure that the equipment is maintained in a safe and effective operating condition for its remaining useful life. If an in-house maintenance department does not exist, the recipient should recommend such a department to the institution's administration.

Evaluation

After installation and operation, the donor and the recipient should assess the level of operational success or failure of the medical equipment donated. This assessment fosters communication between donor and recipient, encourages the continued support of the donor, and allows both parties to learn to improve from previous experience.

The recipient should not hesitate to identify mistakes made by the donor. Of equal importance, the donor should demand honest and timely response from the recipient. The success of future donations will be enhanced as a result of such assessments.

Forms and Checklists

The Medical Equipment Donation Request Form and the Medical Equipment Donation Action Checklist are shown in Figure 43-2 and Figure 43-3, respectively.

National Health Technology Policy

Thomas M. Judd

Director, Quality Assessment, Improvement and Reporting,
Kaiser Permanente Georgia Region
Atlanta, GA

Many countries do not have the health technology (HT) resources that they need in order to improve their populations' health. As defined by the World Health Organization (WHO), HT resources include human resources, pharmaceuticals, equipment and supplies, and facilities. A rational process for identifying, acquiring, and managing needed resources in care delivery requires the development of an explicit policy. The policy should address HT use in all levels of a national health care system. Clinical engineers (CE) around the world have contributed to the development of health technology policies (HTP), particularly as it relates to the medical equipment component. These and other, wider experiences will be discussed in this chapter.

Rationale for a National Health Technology Policy

All countries grapple with limited resources for health. The central issue concerns the best way to use available resources or to plan optimally for future needs. HTPs seek to have the following affects:

- Maximize limited financial investment in health.
- Minimize quality waste.
- Maximize loans and donations.
- Ensure rational use of health resources.

Recommended HTP Elements

A literature search was conducted to identify several models for HTP in developing countries for which the global clinical engineering community has played a significant role. As a result of this survey, the following ten recommended HTP elements emerged as most important:

Political

- HTP is linked to national health policy and health-reform initiatives through the Ministry of Health.
- HTP has a Ministry of Health-led communications plan, internally for the health system and externally for technical aid supporters and donors.

Planning

- HTP is focused on national health priorities, based on their population's epidemiological data.
- There is a rational HTP methodology for planning and management, with multidisciplinary expert panel consensus.
- HTP integrates planning and management for all HT resources.

Assess, Acquire, Manage

- The HTP establishes and supports a technology assessment program, including ongoing input of evidence-based medicine.
- The HTP ensures that the country conducts a health technology management (HTM) process, from planning to acquisition through the full life cycle of resource use.
- The HTP ensures development of HTM capacity in the country.
- The HTP ensures that ongoing activities for quality improvement, risk reduction, and patient safety for HT are conducted in the health delivery system.
- The HTP ensures that a regulatory and legal framework for HT resource research and development (RandD), appropriate business ethics, and resource quality assurance is developed.

HTP Models and Key Features

- Brazil 1989: Binseng Wang advocates a comprehensive medical equipment management approach, integrating RandD and regulation through the equipment life cycle.

- WHO Geneva 1999: Authored by Andrei Issakov and others, this model focuses on equipment, facilities, and related support systems. It provides an extensive "Country Situation Analysis" as well as an HTP framework, guidelines, process flows and checklists that address all elements of HTP.
- WHO Africa Region 1999: Authored by Yunkap Kwankam and others, this model notes that HTP should address health technology assessment (HTA) and HTM, human resource (HR) development, research and communication, and access to information.
- South Africa 2000: Authored by Peter Heimann, Mladen Poluta, and others, this HTP model focuses on equipment, facilities, related support systems, and key clinical services. It advocates a country-wide HT audit, use of Essential Health Technology Package (EHTP) HT resource planning and management methodology, development of HT regulatory framework, HTM capacity building, and recognition that "highly specialized systems" such as transplants require unique management. (See Chapter 45.)
- PAHO 2000: This model by Antonio Hernandez highlights HTP focuses on improving facility and equipment infrastructure in Latin America through intercountry and interinstitutional coordination, and the development of HR and HTM capacity to improve equity, quality, efficacy, and safety.
- England 2000: Authored by Caroline Temple-Bird, this model recommends HTP elements for developing countries that focus on improving facility and equipment infrastructure; addresses HTA, acquisition, life cycle management, and developing HR and HTM capacity, research and local production.
- World Bank 2001: Authored under Yolanda Taylor's oversight, this model of HTP development links all health technology resources, emphasizes life cycle cost analysis and management including HTA, linkage with macro policy and regulatory mechanisms, acquisition and capacity building.
- Mexico 2001: Authored by Adriana Velazquez, this model of HTP development links all health technology resources, provides a focus on telemedicine for the e-health sector, use of HTM in public institutions to assist HTA, acquisition, and overall resource management.
- WHO-EHTP 2002: Authored by Heimann, Issakov, Kwankam, Thomas Judd, and others, this model of HTP development is based on integrated health resource planning and management and on meeting health priorities through resource optimization based on evidence-based clinical practice guidelines.

Case Study 1: HTP Model, South Africa 1999

The following statistics were taken from the remarks made by Nonkonzo Molai at the Advanced Health Technology Workshop held in Cape Town, South Africa, November 1999. (See Chapter 71.)

Health Problems

- Population of 40 million with following 1998 health data/1000 (WHO Region average):
- Infant mortality – 59 (57)
- Maternal mortality – 230 (430)
- Malnutrition under age 5 – 23%
- Health expenditures – 7.9% of GDP (5.2%)
- Leading causes of mortality (Africa) – 8.2% acute lower-respiratory infection (LRI); 19% HIV/AIDS; 7.6% diarrhea conditions; 5.5% perinatal complications; epidemics of HIV/AIDS, malaria, and tuberculosis in region.

Country's Needs, Priorities, and Resources

The level of health service delivery has not improved much in spite of considerable investment in importing new technologies and operational expense of supporting these technologies. For example, the lack of equipment maintenance and repair is a major stumbling block in the effective provision of care and is related to poor planning and acquisition and procurement.

The most important intervention is ensuring a stable supply of competent health technology managers. The Workshop is intended to assist decision-makers and planners in addressing complex issues of planning, life cycle, transfer, management, and utilization of health technology so that plans for education, training, and placement of HTM professionals can be developed.

The Workshop also is intended to impart skills to the HTM community to take actions to ensure and enhance the safety of health technologies and facilities.

HTM is one of the major cost drivers in our health care system within the area of resource mobilization. The broad framework for comprehensive HT policies has been created. Our top priority is the creation of an HT system composed of acquisition, management, planning, and HTA subsystems. The major short-term strategic action is to conduct a comprehensive national HT audit. A second action is to field-test the Essential Health Technology Package (EHTP). Findings from these two activities will be considered in order to determine the level of intervention from government that will be required.

Framework for HTP

Macro Policies

- HT Acquisition Subsystem: This area focuses on reducing the unnecessarily high HT cost that results from the unsystematic and unplanned acquisition and inappropriate use.
- HT Management Subsystem: This is aimed at ensuring safety, efficiency, and effectiveness of HT, which in turn will enhance the delivery of health care services. HTM systems audits will determine needs and capacity for HTM maintenance, HT HR training and development strategies, and further development of HTM systems and structures.
- HT Planning Subsystem: This area focuses on ensuring rational and optimal distribution of HT, at improving equity in access through appropriate use of the EHTP methodology for planning and management of primary, secondary, and tertiary care.
- HTA Subsystem: This is aimed at ensuring appropriate introduction, adoption, and continued use of appropriate HT in the country.

Operational Policies

- Review existing and prioritize policies that need development based on concrete examples; e.g., budget figures and waste incurred in HT due to wrong practices that require prompt attention.
- Develop HT-related policies for HR, intersectoral collaboration, and HT information systems.

Mission and Desired Outcome

The mission of health care planners and policymakers is to ensure that health technology is harnessed to its fullest extent as one of the tools to improve the delivery of health services and to devise a strategy that facilitates appropriate utilization of health technology for the South African health system. The desired outcome is a unified and harmonious HT system that ensures optimal distribution of the limited HT resources and facilitates equity in access, with the ultimate aim of improving the quality of health services.

Case Study 2: HTP Communication Plan – Example of WHO African Region, 1999

WHO convened Region member states and established a HT Task Force to provide assistance to member states. It produced two important documents (Guidelines for Donation of Health Care Equipment and Guide for the Formulation of National Health care Equipment Policy) as key communication tools. The policy tool is summarized below:

Guiding Principles for Health care Policy Development

- To give HT policy high priority as an essential component for the comprehensive development of the health system and for ensuring the improved equitable access of the population to affordable and sustainable quality care.
- To plan the introduction of HT and to manage it properly, taking into account the needs and aspirations of the population, the environment and its trends, and available resources.
- To systematically give preference to the technological options that, for the same life cycle cost, have proved their effectiveness in the region and in other countries in similar contexts.

Executive Summary of Report and Communication Plan to Region Member States

- Health for all through primary health care, proclaimed in Alma Ata in 1978, will remain a major goal in the coming years and century.
- To achieve this goal, the majority of countries in the region are reforming their health systems and services in order to ensure equity in health and access to health care.
- Technology development has played, and continues to play, an essential role in promoting health care delivery.
- The scope of health technology is very wide. This document focuses on medical equipment, one of the major concerns of the region.
- The policy statement and strategy for its implementation proposed in this document aim to help member states to formulate HTP and plans that support the achievement of national health care policy.
- Priority interventions for HT should address: (1) technology management; (2) human resources development; (3) research and communication; and (4) access to information.

- The Regional Committee is invited to examine the proposed document, make suggestions for its improvement, and adopt it in support of the health-for-all policy in the region.

Financial, Medical, Public Health Benefits

Technology can play a key role in achieving the objectives of health sector reform, particularly better access to health care by the population, greater equity, improved quality of care, and increased cost-effectiveness of health services. A rational health technology policy for each country can solve many common problems. Purchase price of equipment is usually only a small fraction of life cycle costs. In all procurements, provision should be made for coverage of recurrent costs that reach the annual rate from 3%-8% of the purchase price.

Target Groups and Communication Strategies

The ministries of health (MoHs) in the member states should be the main targets and conduits for information on health technology policy. Partnerships should be encouraged among the respective MoHs and other government bodies, nongovernmental organizations (NGOs), consumer groups, the private sector, and industry.

WHO should focus its activity at the country level by embarking upon advocacy vis-à-vis policymakers and health officials to create the political will to include HT policy in the list of national policy priorities and to identify and mobilize institutional partners so as to benefit from their support. This political will should result in the establishment of appropriate mechanisms and tools for the implementation, monitoring, and evaluation of the HT policy. At the regional level, measures will focus on endorsement by member states, leadership to support of HT policy in national health development priorities, and implementation of relevant national plans. A recommended HT-awareness campaign and communication plan for South Africa should include the following actions:

- Debunking myths (e.g., that HT is synonymous with expensive HT such as MRIs and CT scanners)
- Showing relevance and appropriateness
- Tailoring policy to a country's objectives and strategies
- Ensuring that HT is seen as a tool and a resource
- Not losing sight of the end objective, which is to improve patient care

Case Study 3: The Experience of Mozambique

Enrico Nunziata, clinical engineering consultant to the Ministry of Health of Mozambique from 1997 to 1999, reported the following (Nunziata, 2003): After 10-15 years of technical assistance, the maintenance system was stagnant after externally funded projects ended. In 1997, an HT policy was developed and approved within the MoH "Modernization Program" for the Administrative and Management Sector of the health care system. In 1998, the new administrative structure was introduced at all levels. A new medical equipment management system (MEMS) was developed and introduced, and a sub-Sector General Action Plan (GAP) was developed, approved, and presented to participating donors. In 1999, the GAP became known and accepted and became a tool for the local HT manager and a reference point for donors. Data collection for MEMS became more regular, and an economic study was performed to evaluate real maintenance cost to correct the GAP for introducing future options. By 1999, a new breed of engineers was attracted to enter the system. HT policy was a first step, but providing appropriate HT was still dependent on foreign aid and technical assistance. The development of HT maintenance capacity remained strongly dependent on other MoH sectors.

Case Study 4: The Experience of Brazil

Context and Structure

The 1990s were a time of national health system reform in Brazil with decentralization and unification of public and private health services. A new HTP was needed for Sao Paulo State's 560 hospitals (approximately 85,000 beds), 2100 clinics, and 10 research and manufacturing facilities providing care for 33 million people. Toward this end, the Office of Equipment Advisor to the Secretary of Health was established. Binseng Wang, advisor from 1987-1990, implemented a structure that addressed all aspects of the equipment life cycle listed below:

- Planning
- Procurement
- Acceptance
- Commissioning
- Maintenance
- Refurbishment
- Decommissioning

Regulation and research and development were incorporated in the plan in an effort to control the safe and effective use of medical device technology and to encourage the growth of a native medical device industry.

Opportunities and Critical HTP Success Factors

Opportunities

- Insufficient financial resources required careful planning with input from all stakeholders.
- Inadequate infrastructure required use of creativity to use efficiently what is available.

- Lack of trained human resources required an investment in education and training.
- Difficulty in acquiring HT equipment spare or repair parts through alternative sources.
- Missing equipment documentation led to inclusion in acquisition agreements and assistance from global colleagues.

Critical HTP Success Factors

- Keep decision-makers well informed.
- Create a strong link between health policy and HTP.
- Secure wide stakeholder support.
- Use transparent and rational methodologies for planning, management, and support of technology.
- Develop a strong evaluation system that includes feedback from equipment users, equipment service staff, and patients and to policy makers and stakeholders.
- Emphasize education and training to build HTM capacity for the long term.
- Plan for equipment replacement and continuous equipment service support.

Case Study 5: The Experience of Kenya – Late 1990s, John Paton, GTZ/MoH

- MoH of Kenya initially wanted standardization of equipment for management and spare-parts reasons.
- MoH adopted international standards for accurate and detailed equipment specifications.
- MoH modeled development of HT Policy on existing drug-policy document approved by Parliament and in wide use in Kenya.
- A draft policy was developed by an MoH working team. All relevant stakeholders in the health delivery system were asked for comments. A workshop was convened to develop a consensus-based final document.
- The HTP policy was seen as a first step. It was kept broad and is subject to ongoing review and update regarding goals, requirements, and responsibilities.

Case Study 6: EHTP—A Rational Planning and Management Framework for Kyrgyzstan, 2000–2004

Overview

The Essential Health Care Technology Package (EHTP) is a new methodology and set of tools that was specifically developed to strengthen health resource planning and technology management. These resources, termed “health technologies,” are, primarily pharmaceuticals, human resources, medical devices, and facilities. Figure 44-1 shows the main elements in the EHTP. (See Chapter 45 for a detailed description of the EHTP.)

The link between resources and the delivery of quality care is achieved by identifying all health technologies that are needed to provide well-delineated promotive, preventive, and curative health interventions. Health interventions in turn are linked to the WHO International Classification of Diseases (ICD9, ICD10) and other disease classifications (e.g., ICD9-CM). This mapping between HT and health care interventions is based on internationally accepted and recognized clinical practices. It is expressed in the form of a “matrix,” or generic template, whose elements include economic, technical, and other information typically associated with acquisition of HT and with their utilization in providing the interventions. This EHTP matrix is the basis of the EHTP methodology and tools, which are implemented in a suite of software packages. Each intervention is decomposed into progressively smaller components, all the way down to procedures and associated techniques. The decomposition uses the Current Procedure Terminology (CPT) of the American Medical Association. Over 350,000 links thus have been created between international classification of diseases and the CPT.

One unique and powerful feature of EHTP is the integration of epidemiological profiles and recognized clinical practices (such as clinical practice guidelines [CPGs]) with the EHTP matrix. This allows advanced modeling and simulation for identifying economic and other resource requirements given varying scenarios of disease incidence and prevalence and CPGs. Conversely, simulation can indicate the epidemiological conditions that can be covered with available resources by using specific CPGs.

Implementation in Kyrgyzstan

EHTP was developed over several years and provided by the WHO Department of Health Service Provision and the Medical Research Council, South Africa, to WHO member states beginning in 2000. In 2001, the Kyrgyz Republic (Kyrgyzstan) Ministry of Health (MoH) requested implementation. Goals and objectives include:

- Applications in the broad context of health systems development and reform and thus aligned with and possibly able to accelerate present health reform efforts.
- Methodology and computer-based tool expected to measurably improve effectiveness, efficiency, performance, and quality of health delivery.
- Ability to overcome past fragmented and often untimely efforts to plan for and manage health resources through WHO-designated essential lists.
- Simplified coordination of resources by central, district and local health leaders and integrated management of these resources to allow more efficient distribution.
- Focusing on the country’s disease burden, as defined by in the Kyrgyz Republic by MoH and the National Drug Council, who direct the national CPG development process.
- Use of best medical evidence to direct care at primary, secondary and tertiary levels by selecting interventions or CPGs best fit to available financial resources and existing constraints.
- Methodology and tool may be dynamically updated with advances in medical technology.

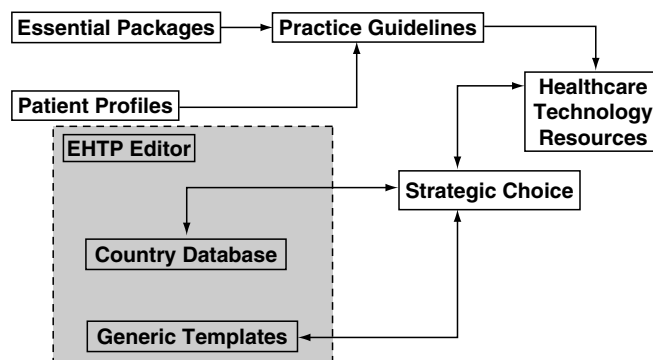

Figure 44-1 Essential Health Technology Package simulation.

- Piloted at three sites for primary and secondary level care in 2003, with nation wide implementation in 2004.
- Pilot sites initially used EHTP to better manage five target conditions selected by MoH and pilot leaders: Hypertension, acute respiratory illnesses in children, iron deficiency anemia in pregnancy, brucellosis and tuberculosis (TB).
- Quality, cost and accountability indicators were developed and measured.
- The implementation process is overseen by a MoH national commission that includes a national coordinator, expert resource working group leaders, coordinating office team, and WHO technical advisors.

Initial Findings at Pilot Sites

- Three secondary level hospitals and their primary level clinics have significant CPG noncompliance:
- Pharmaceuticals: Problems featured overuse of recommended drugs, use of obsolete drugs, or drugs not priced affordably in the pilot area.
- Equipment: Recommended diagnostic lab and imaging tests were not completed because of lack of appropriate equipment or lack of supplies to operate equipment (e.g., lab reagents, chest films for X-ray, or appropriate X-ray and ultrasound equipment).
- Human Resources: Overuse of physicians occurs, notably at the secondary level; nonphysician staff competencies are not defined, resulting in a wide variation of staff utilized at both levels.
- Facilities: Because pilot sites chosen at locations whose facilities already had been modified to meet new health reform standards based on “case rates” instead of population size, facilities were adequate to meet requirements of CPGs.
- Resource running costs were measured for all resources (e.g., initial and ongoing training of staff; maintenance and operational costs for equipment and facilities; and variable costs for drugs in a given area).

Key Definitions and Applications

EHTP “Simulation Tool” software: allows for the integration of linked interventions to CPGs, health and patient profiles and health packages. Definitions and explanation of terms as they apply to EHTP are presented below.

Scenarios

- Scenarios are graphical interface and/or representation of CPGs.
- MoH-approved CPGs are used to direct care providing best clinical outcomes and optimal use of limited resources for clinical conditions that are most prevalent in country.
- The pilot had 30 primary and secondary CPGs programmed in EHTP Computer Tool.
- The scenarios can be used to map published CPG and clinical/nonclinical pathways based on HT-linked interventions (procedural steps, involving a specific clinical technique, each with known health resources required, called the “technology lists” [described below]).
- The graphical interface allows easy interpretation of CPGs and allows easy modification and editing of CPGs. Scenarios are saved in unique files, thus allowing easy sharing and Internet distribution. CPGs can be based on existing evidence-based CPGs from other countries, thus reducing development time.

Technology Lists

- Centrally validated previously for each of four resources needed for each procedural step of CPGs; or each box/health intervention in CPG flowchart mapped into EHTP Computer Tool. In pilot, Technology Lists were validated at primary and secondary levels.

Patient Profiles

- Patient profiles are separate modules that can be used to graphically display patient utilization of scenarios.
- Patient profile data can be based on epidemiological data.
- Historical data can be recorded. Statistical mapping of future data based on epidemiological data can be used to plan for future interventions.
- Pilot locations mapped profiles for each of 30 conditions for 2002 to use as a baseline.

- When combined with the Scenarios and validated Technology Lists for each CPG, will allow local health leaders to calculate resource requirements to treat that condition throughout a given year.
- Profiles are a unique method of quantifying magnitude to CPGs. Based on timing of scenarios and interventions, resource scheduling is an integral part of patient profiling.

Scheduling

- Intervention scheduling forms the basis for the calculations of resources within scenarios.
- Resources scheduling may be based on actual intervention's time periods or resource utilization within the scenarios, taking into account known resource constraints. (For example, consumables, surgical instruments and linen are calculated on procedure length.)

Resource Constraints

- Scheduling of resources can be calculated within predefined resource constraints.
- Constraints that can be predefined are resources availability (e.g., human resource and competency availability, medical device and infrastructure availability, and the availability of pharmaceuticals).
- Time constraints for human resource availability, holidays, and working hours can be set and included in the model. Other constraints, such as effectiveness of certain support services, can be set to be included in the calculation of the scheduling process.

Health Packages

- Health packages are a graphical interface used to link scenarios and patient profiles.
- Multiple linked scenarios and health profiles represent a set of services delivered at a point of care. For example, caesarean section, antenatal care, and pre-eclampsia would be part of a mother-and-child health package for a specific level of health care intervention, or all of the services delivered at a specific pilot site could be a health package.
- Health care packages can be saved in an EHTP-specific file format, thus allowing easy sharing and distribution on the Internet. Any number (system dependent) of scenarios and patient profiles can be associated to define the health package.
- Resource requirements derived from the EHTP health packages are calculated based on the actual time schedules, patient profiles and loads, and their applicable CPGs.
- Health packages were developed for each pilot site; when combined with the Scenarios with validated Technology Lists for several CPGs, allows local health leaders to calculate aggregated resource requirements to treat the many conditions throughout the year and to develop resource-sharing strategies as appropriate.

Country Database

- Country-specific databases are derived from the Generic Template provided by WHO to the national coordinating office team, under the oversight of the EHTP national coordinator and commission. The EHTP Generic Template provides a single reference database with relatively complete information on all known health resources and health interventions in the world. This comprehensive database is vital in ensuring a manageable updating and synchronization process for country-specific information.
- The country databases are a subset of the generic database and usually reflect the country-specific needs and practice, as does the Kyrgyzstan country-specific database.
- The subset of the country databases are then modified (over time) to reflect the specific country conditions.
- This process includes the modification of the macro properties (i.e., procedure timing and actual health care technologies that are needed to perform the intervention).
- Micro properties are also changed. These include details such as quantities; technical details and specifications; costs and medical device maintenance; and management details.
- The ability to change details at both the micro and macro level of care, scenarios, patient profiles, and health packages provide complete flexibility and allows users to adapt their planning scenarios to virtually any conditions applicable in their target setting.

Costing of Interventions

- Costing of clinical and nonclinical interventions within the health sector is complex. The unique association and interaction of health care technologies required to provide services is not well defined and changes from country to country.
- The EHTP methodology of unbundling all services and interventions into their respective health care technologies provides a unique opportunity to attach costs, scheduling, and quantities to all elements.

EHTP Costing Capabilities

- Unit costs for all HT, including recurrent, installation and training costs.
- Intervention costs are determined by compounding the costs attributed to all HT for a single intervention.
- Stringing health care interventions into CPGs allows the costing of interventions based on practice and takes into consideration medical ethics and quality considerations.
- The combination of CPGs further refines the costing module, as resource-sharing based on clinical practice can be determined.
- The costing module can be used to determine unit and marginal costs for any area of health service delivery and planning. New and additional costs can be determined for services.
- The costs of certain HT within a bundle of services can be determined. Cost factors associated with increasing the level of demand, quality, and service provision can be modeled.
- Increased costs associated with the introduction of new techniques, medical devices, or drugs (and any combination thereof) can be quantified and evaluated.
- Cost evaluations of providing a new service within an established service portfolio also can be appraised and quantified in terms of its base resources.

Other Applications

- EHTP provides a unique platform of mapping the current services' portfolio complete with actual resource requirements and costing data.
- EHTP thus provides a mechanism to set the virtual target and to compare the effort and cost required, thus improving the current health care system to a planned and envisaged system.
- The costs and additional effort required can be determined and can form a significant evidence base for decision-makers in their approach of improving health.
- EHTP thus provides an appropriate tool to establish both a current and projected list of services that can be used by donor and technical assistance agencies, nongovernmental organizations, and consultants, to plan their support.
- This planning process can be used primarily to determine the direct needs, such as medical devices and pharmaceutical and human resource needs, but it also quantifies the extra support that is required, to cover the indirect requirements, such as maintenance and other recurrent costs.
- EHTP also can be used to determine the donor agencies that can support a given area within the complex set of requirements. EHTP provides a useful tool for donor agencies to make more effective interventions and also provides a guide to recipient countries to gauge and prioritize their requirements, as well as to base new requests on evidence.

Conclusions

There are several models to assist developing countries for creating effective health technology policies. Some of the case studies highlight medical equipment management (HTM) best practices and others demonstrate a broader view of HTP and its implications. Clinical engineers continue to contribute significantly to these efforts. The reader is encouraged to contact those individuals noted in the reference section to discuss ways in which this work can assist the reader's efforts in this regard.

Geneva, Switzerland

Global economic, political, and social changes, as well as an increased and changing disease burden, have generated widespread efforts to reform and adapt health care systems to improve their efficiency, equity, and effectiveness. Health authorities worldwide are increasingly concerned with defining policies and strategies to contain growing costs of care within the context of serious economic constraints while trying to preserve the health system's social imperatives of equity and solidarity. At the same time, health care systems in all countries, rich and poor, become increasingly more technology dependent, and as health care technology continues to evolve, so does its impact on patient outcomes, hospital operations, financial efficiency, and overall performance of health services and systems (Heimann and Issakov, 2000).

Technology has a paradoxical role in health care systems. It is frequently cited as the most significant contributor to the unacceptable cost increases while at the same time it equips health care providers with indispensable tools to perform their functions more effectively and efficiently. The promise of new technologies is becoming increasingly familiar to populations. Rising public expectations for better health services combined with growing market and professional pressures for introducing the latest technological advances into practice have commonly led to the perception that the quality of care is directly linked to the sophistication of technologies used in providing that care. In many instances, however, the high expenditure related to the introduction of costly and complex new technologies is not justified by the overall benefit achieved in terms of access, quality, and health outcomes (Issakov, 1994a). Moreover, expansion of health care infrastructure and proliferation of technologies have far outpaced the capacity of many countries to effectively absorb, adequately support, and fully utilize these technologies, thus creating serious imbalances in health services provision.

Within this paradigm, health care technology (and in particular, related management strategies), have repeatedly come under the spotlight as health care providers seek to identify cost-effective methods for providing equitable and quality health care (World Bank, 1993). It is commonly accepted that only rationally planned health care technology interventions based on a sound needs assessment and ensured life cycle support provision can maximize their potential benefits, contain costs, and improve health outcomes rather than become a long-lasting burden on scarce health sector resources. However, the ability to realize this is a major challenge faced by health care decision makers and other health professionals in many countries. It is compounded by the lack of appropriate management tools for optimizing the deployment of health care technology and facilities that house it and those for matching the country need and capacity with available technology options.

Responding to this urgent need of the World Health Organization (WHO) member states for a comprehensive tool to assist in better planning and management of health care technology interventions, WHO and its Collaborating Centre for Essential Health Technologies at the South African Medical Research Council (MRC) in Cape Town embarked in 1996 on a major research and development initiative. This work has resulted in developing the concept, methodology, and software-based tool called Essential Health Care Technology Package. EHTP ensures that health care technology interventions are properly assessed and successfully implemented and helps to make informed decisions on acquisition, deployment, and utilization of health care technologies, thus contributing toward cost-effective, quality and equitable health services delivery. It also helps in defining the essential services that are affordable and sustainable by identifying and quantifying all kinds of essential resources needed to perform required procedures for the majority of common and prevalent diseases and health-

related conditions. Broadly, EHTP is instrumental in translating strategic plans into operational realities.

The Essential Health Care Technology Package

The EHTP, therefore, is both a methodology and a tool aimed at strengthening and optimizing health care technology planning and management. The methodology is based on the hypothesis that effective health care delivery can be realized only if all health care technologies (e.g., medical devices, drugs, human resources, and physical infrastructure) are available and correctly managed to deliver that care.

The Context

There have been significant changes in the scope and complexity of health services provision in the last few decades, and the recent introduction of "high-tech" and other sophisticated health care technologies has necessitated the establishment and strengthening of complete support systems and services. Unfortunately, the rate of health care technology deployment has far outpaced the rate of implementation of these support services, which often has resulted in health care technology management inefficiencies, as clearly demonstrated by the high percentage of inoperable and unused medical devices.

These constraints have forced health care providers and decision-makers to refocus their attention on optimizing existing health care systems in particular, at improving health care technology management, and on reassessing the important role that health care technology plays in the provision of quality health care. The identification of appropriate health care technology interventions and the optimization of the delivery process within the framework of financial constraints and changing technology environments have become paramount in any health care and delivery planning process. Globalization and the need to be competitive have placed a further demand on health care providers to ensure that the real needs of the people are addressed and optimized.

Identifying and assessing the real needs of any health care system and ensuring that the health care technology base in a country adequately supports the delivery of health care have become aspects of any health care planning process. The need to base decisions on sound evidence has also gained significant momentum and has become an integral part of the health care planning process. Linked to this process is the development of tools that are flexible and responsive to changes in burden of disease and changes of complexity and availability of health care technologies.

The transfer of health care technologies further adds to the complexity of the health care planning process and often results in significant technology transfer mismatches, particularly in the process of technology acquisition through donor aid (World Bank, 1994). One consequence of this mismatch is the inability of less-developed countries to absorb and fully utilize health care technologies effectively, especially new and sophisticated technologies. This problem is compounded by a lack of adequate technical support structures and skilled users and by increasing financial constraints. While the rate at which technologies are being developed and introduced into the regional markets is increasing, the ability of health care systems in these countries to utilize these technologies fully is likely to decrease. For these reasons, it has become widely accepted that what is needed is improved management and planning of health care technology throughout its life cycle.

Health Care Technology Management

The goal of health care technology management (HTM) is to optimize the acquisition and utilization of technology to achieve maximum beneficial impact on health outcomes at the national level. At the organizational level, HTM is an accountable, systematic approach to ensuring that cost-effective, efficacious, safe, and appropriate equipment is available to meet the demands of quality patient care. HTM is a complex multidisciplinary process that can have substantial positive impact on health care outcomes provided that proper attention is given to political, organizational, economic, cultural, ethical, and legal aspects of technology interventions and their management. As part of this process, extra care must be exercised to ensure that those technologies that are acquired and deployed have maximum positive impact on health outcomes and that they can be utilized effectively and supported to ensure sustainability of the interventions.

To ensure effective HTM, therefore, a framework within which these aspects can be incorporated must be identified and quantified. While aspects of HTM have been considered in detail, these contributions often apply to a specific context and timeframe and are presented with varying degrees of observer bias (Medical Alley, 1995; Webster, 1979; Free, 1992; Barnes, 1990; Banta and Andreason, 1990; Drummond, 1994; Scenarios Commission, 1987; Jennett, 1988; McKie, 1990; Goodman, 1992). One further shortcoming of current approaches is that most if not all have been formulated in the setting of an industrialized country. These approaches—explicitly and implicitly—make assumptions relating to many components of HTM, from skills of individuals and resources available to the technical and organizational infrastructures. Moreover, most of the current approaches focus on technical issues without sufficient consideration of the complex and dynamic human factors in the management process and the differing HTM environments in less-developed countries (Issakov, 1994b). This is being realized increasingly in many areas of health care technology management.

HTM research in many developing countries is limited, and even experience and knowledge that have been gained have not been widely disseminated. In particular, the link between the research community and decision makers is tenuous, and in many instances it does not exist at all. This is not unique to the degree of development, but the implications of this shortcoming are perhaps more serious than in the industrialized countries. Moreover, the positive impact that continued research could have in the decision making process is not fully realized because many countries in the region continue to rely on intermittent, ad hoc information sources for decision making.

It has been shown that better HTM is urgently required as an integrated component of the health care delivery process to ensure both sustainability of the health care system and an improvement in the quality of care (Commonwealth Regional Secretariat, 1995). It will be especially important to be able to predict, measure, and assess the effectiveness and impact of health care technology interventions and thereby to optimize their implementation and utilization. In order to achieve this, the elements of the management process—and their interaction—must be identified, and this can only be done through effective and appropriate research.

Justification/Rationale

In the process of health sector reform, special care is being taken to ensure that the implementation of reforms does not result in unwanted or unnecessary consequences. Changes in the health care sector generally are preceded by a comprehensive analysis of the prevailing situation, and medical audits and needs assessments have been conducted to identify real and perceived needs and to ensure that the health sector reforms are effective (WHO, 1995a; WHO, 1995b; WHO, 1996).

Due to the seriousness of the situation in many countries and the shortage of time available in which to achieve the desired changes, much of the data that have been used to justify the reform process have been extrapolated from few studies. Similarly, information on health care technology assessment and management practices is limited, and thus reforms in these fields are also based on few studies (ISTAHC, 1994). However, important studies covering many WHO member states have indicated the existence of a management crisis in most phases of the technology life cycle.

Historically, the methods of technology procurement and the organizational structures for this process have resulted in a general lack of accountability for the capital investments made. Few facilities have an effective inventory system, particularly for technology items, and therefore health care technology-related information is not available at the district, regional, or national levels. Stock taking and asset management are not performed (indeed, they are not possible) at any level of the health care system in many countries. Assessment of health care technology interventions is therefore not possible, and this situation severely hampers effective overall management.

A significant investment must be made in order to correct the problem. Unfortunately, there is no “quick fix” solution, and the problems currently experienced are merely symptoms of complex and interrelated shortcomings of the HTM process within the constraints imposed by the health system and general environments.

Health care technology is not necessarily linked to health outcomes, as is clearly demonstrated by the lack of appropriate health care technology policy and planning in many countries. Health care technology is often purchased on an ad hoc basis and generally is linked to the prevailing availability of funds rather than to a planned acquisition strategy. One typical consequence of this approach is the large proportion of medical equipment that is unused and/or nonfunctional; as much as 70% of the equipment does not function in certain countries.

These basic issues and their relationship to the efficiency of technology interventions are thus key elements in the understanding of the HTM process. Research is needed to link these to the entire management cycle and thereby to create a tool for effective decision making (Attinger and Panerai, 1988).

Research from the health systems paradigm also must be incorporated into an integrated assessment of the health care technology intervention process. This implies that health care

technology must be linked to health outcomes and that the HTM process must be defined and quantified to ensure that decision makers are able to predict and manage health care technology interventions as an integrated element of health care provision.

Although health care technologies are often blamed for the high rise in costs associated with the provision of health care, very little evidence-based research has been offered to support this assertion. In fact, very little research has been done to establish the impact of health care technology on health outcomes. This is evident from the difficulties that researchers and planners have in linking technology with health care outcomes and in measuring quality-of-care indicators such as QALYs (quality adjusted life years) or disease burden indicators such as DALYs (disability adjusted life years) (Murray and Lopez, 1994; Mooney and Creese, 1995; Prost and Jancloes, 1995).

What is needed therefore is an initiative to address these issues in a global manner. It is proposed that the primary step was to develop an EHTP that would provide a planning tool for health care planners in terms of the management of health care technology, contribute to greater efficiency of health care technology resources, and facilitate improved management and support of the technology interventions (Hanmer et al. 1994; WHO, 1994; AFTH/MRC, 1995).

The EHTP, through its formulation and implementation, will help to ensure that technology interventions in the health sector reforms process can be properly assessed and successfully implemented. The package will provide governments, donors, policy formulators, and decision-makers with much needed tools to facilitate improved management of health care technology and thereby to ensure that cost-effective and equitable interventions can be provided at all levels of health care delivery. The EHTP will be equally useful for developing and developed countries alike.

Package Development

Methodology

The EHTP is a methodology and a tool aimed at strengthening and optimizing health care technology planning and management. The methodology is based on the hypothesis that effective health care delivery is possible only if all health care technologies (e.g., medical devices, drugs, human resources, and physical infrastructure) that are needed to support the health care delivery process are available and correctly managed. This implies that all health care interventions (which can either be promotive, preventive, or rehabilitative) that comprise the health care delivery process must be supported by the correct ratio and nature of medical devices, drugs, human resources, and physical infrastructure. For example, an appendectomy must be supported by the correct combination of medical equipment, surgical instruments and support equipment (medical devices), physician and nursing staff (human resources and knowledge), medical gases and anesthetic agents (drugs), and an appropriate surgical setting (physical infrastructure) in order for it to be successfully implemented and executed.

The ratio and magnitude of the combination of health care technologies will depend on the skills and clinical practice that are applicable for each technology used in each stage. The lack of one or more of these health care technologies clearly may have an impact on the effectiveness and/or on the ability to implement the desired intervention. In many cases the omission of critical and essential health care technology elements would impede the viability of the specific intervention. However, there are many interventions (in particular, promotive health care interventions) that require only one or two health care technology elements in order to be implemented effectively.

The objective of the EHTP therefore is to identify and quantify the above-mentioned nature and ratio of health care technologies for all medically recognized health care interventions. Figure 45-1 represents the relationship between health care interventions and their corresponding technologies. Health care interventions (i.e., promotive, preventive, or rehabilitative) that are represented on the x-axis can be linked to a corresponding medical device, human resource, and/or physical infrastructure, thus forming the EHTP matrix. The EHTP matrix is developed for all levels of health care delivery, thus reflecting the different nature of services and clinical practice, technological complexity, and sophistication of health care technologies that will be applicable to and realistic for the different levels of health care.

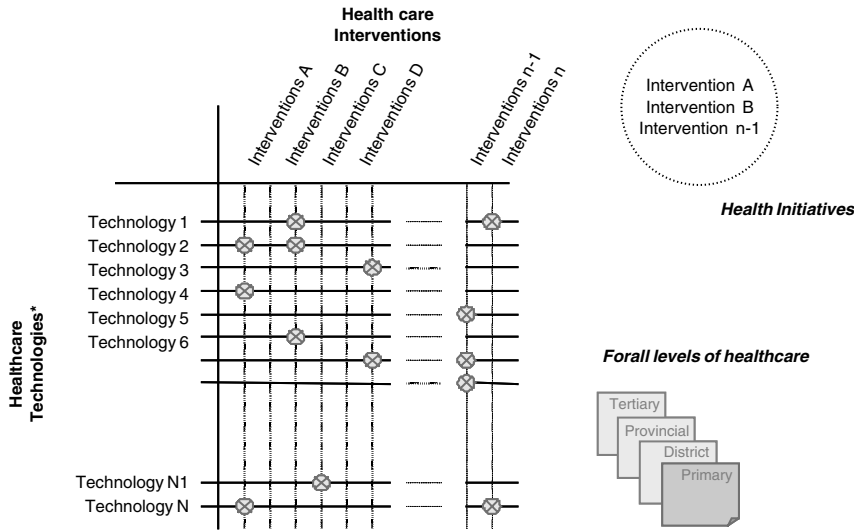

A three-dimensional matrix is therefore developed reflecting the inter relationship among health care technologies, health interventions (x and y-axes as in Figure 45-1) and levels of health care delivery (z-axis). This relationship provides the basis for a powerful management and planning tool since it enables health planners and decision makers to quantify and qualify similarities and differences in health care interventions (with respect to health care technologies), thus providing an unique platform to integrate services into more efficient and effective health care packages.

Linking the health care technologies to their corresponding interventions is based on current clinical practice and therefore is time and knowledge dependent, so the EHTP matrix is not universally applicable but must be adapted to become country-specific. Alternatively, it does not prescribe clinical practice but merely provides a basis for currently available methodology.

Logical Framework

The EHTP logical framework is based on linking existing and proprietary information sources such as the International Classification of Diseases (ICD) database and the Current Procedure Terminology (CPT) database with medical equipment, human resources, facility databases and drugs databases (Figure 45-2). The changes in extent and rate at which the contents of database change necessitates that updated proprietary databases (e.g., ICD and CPT) are incorporated into the EHTP package to ensure that up-to-date information is always available.

As shown in Figure 45-3, the ICD and CPT databases are cross-linked. In addition, three versions of the International Classification of Diseases database (ICD 10, ICD 9 and ICD CM) have been cross-referenced to expand the user base of the EHTP package.

*Medical devices, Human Resources, Drugs, Facilities

Figure 45-1 Two of the three dimensions of the EHTP matrix are shown above. The matrix represents the relationship of health care interventions and health care technologies. Health care technologies include medical equipment, human resources, drugs, and facilities and represent the mix of these health care technologies that are needed to perform a specific intervention. The interventions may be preventive, promotive, and rehabilitative health interventions. The EHTP matrix is developed for all levels of health care. A particular health initiative requires specific interventions, as indicated in the circle.

Currently there are more than 225,000 established links between the ICD and CPT databases.

The health care technology databases (i.e., medical equipment, drugs, human resources, and facilities) are then linked to the procedures database. This process is guided by the expertise of medical societies, experts, and individuals using their respective fields of knowledge. The process described above is used in the development of the EHTP template database, which will be described in detail below.

Figure 45-3 represents the logical framework of the linked database of the EHTP package. Each rectangle represents a proprietary database. The International Classification of Diseases Databases, ICD 9 and 10 (shown in orange) are the work product of the WHO and have been cross-referenced as described above. The link to ICD 9CM has been provided in order to ensure that countries using the Clinical Modification (CM) of the ICD 9 also will be able to use the EHTP software package.

The cross-referenced ICD databases have been linked to clinical procedures via a template that contains more than 225,000 links to the CPT procedure database, which is the copyright of the American Medical Association. This link of the procedure databases to proprietary health care technology databases (UMDMS, HR, DRUGS, and FACILITY) forms the EHTP template.

One standard feature of the EHTP database is the essential equipment (EEL), human resources (EHRL), drugs (EDL), and facility (EFL) lists, as shown in Figure 45-3. Limited querying and analysis tools are incorporated into the EHTP template software to provide limited functionality and analysis capabilities.

The EHTP package contains two main components. The first is the generic template (Figure 45-4) that has been described above and is used to develop the EHTP generic template database. In addition, the generic template forms the basis, which is modified by countries to reflect their specific conditions and realities. The second component of the EHTP package is the development of simulation tools, as shown in Figure 45-4. This package incorporates the generic template database and allows access to the generic template. The simulation tool is the actual package that provides the front end to health care planners to simulate and plan health care technology interventions as part of health care delivery.

The simulation tool contains four main components. The first incorporates the economic analysis of health care technology. Basic economic information, such as medical equipment fixed and recurrent costs, human resource costs, drug costs, and facility costs are stored in the generic EHTP template database and are accessed by the Simulation Package. Here the stored costs are applied to the simulation tools, and costing analysis becomes available.

The other elements of the simulation tools are structured in the same way. They include analysis tools for clinical, epidemiological, and related medical equipment infor-

mation such as maintenance requirements. Accordingly, health care planners can simulate various possible health care delivery scenarios by varying cost, human resource and medical equipment availability without changing the EHTP template database and without much effort.

The template database information can be updated whenever new versions of the proprietary database become available. This incorporation of the template database thus provides an up-to-date database for planners and also provides a conduit for them to sample both the latest developments of medical equipment and classification of diseases and preventive, promotive, and curative procedures.

Figure 45-4 further shows that the entire EHTP package is made up of two separate components that share a common core or template database. As will be discussed below, the separation of the two systems assists in the implementation of the EHTP as the generic template must be modified to produce the country-specific core database before the implementation of the simulation tools.

Additional modifications have been undertaken on the generic EHTP template database. In Figure 45-5, the incorporation of the EHTP classification database for the Integrated Management of Child Illness (IMCI), Integrated Management of Pregnancy and Childbirth (IMP AC) and Adult Lung Health Initiative (ALHI) is shown. These classifications of interventions, as defined in these special health initiatives, are directly linked to the CPT database. The WHO identified this requirement because many health interventions are performed without identifying the underlying disease, and this applies in particular at lower levels of health care delivery (e.g., clinic and health center).

The incorporation of this modification of the EHTP methodology does not alter the development of the EHTP generic template database. Substantially more effort will be required in the development of the EHTP simulation tools. The link between the diagnostic codes (the ICD databases) and the CPT procedures database needs further elaboration, however. In Figure 45-6, a breakdown of the complete linking process is given. The ICD classification has been divided into its root classifications, which are represented by Category, Block, Sub-block and Intervention. This representation of the disease classification codes follows the WHO coding structure. Therefore the category is represented by an alphanumeric code (e.g., 000-099 for pregnancy, childbirth, and puerperium). The Block is a subset of the category classification and is represented by the subset of the coding (e.g., 080-084 for delivery). The Sub-block and Intervention are represented by 080 for single delivery by forceps and vacuum extractor and "080.1" for low forceps delivery.

The next element is an artificial step called "Step," which was included to differentiate between diagnostic and therapeutic "Interventions." Many interventions performed at

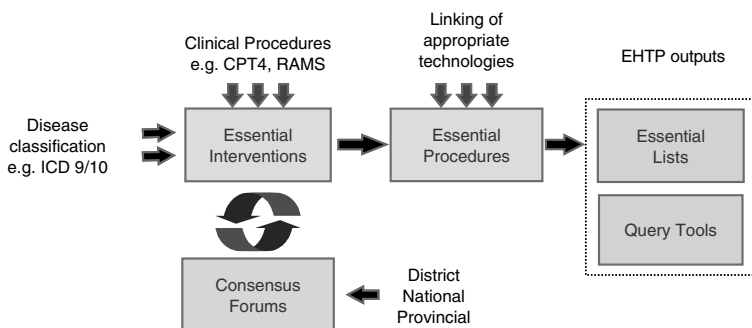

Figure 45-2 The point of origin for the EHTP is disease classification. The disease classifications are linked to clinical procedures which in turn are linked to appropriate technologies, which include medical devices, human resources, drugs, and facilities. The essential interventions are selected by modifying the EHTP templates through a process of country-specific consultations and consensus. EHTP output includes Essential Lists for Human Resources, Drugs, Physical Infrastructure and Medical Equipment. In addition, powerful query and simulation capabilities ensure maximum benefit for health care planners.

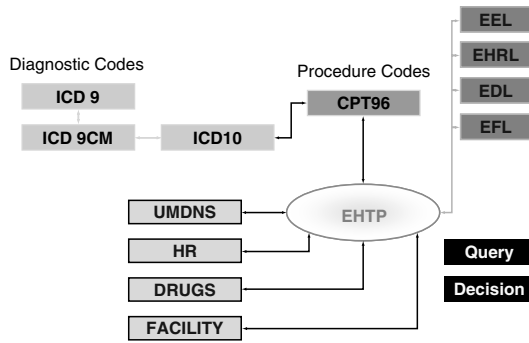

Figure 45-3 The EHTP logical framework. The disease classifications databases (ICD 9, 10 and 9CM) are linked to the clinical-procedures database (CPT), which in turn is linked to its appropriate technologies through linking medical devices (UMDNS), human resources (HR), drugs (DRUGS), and facilities (FACILITIES) databases. This link provides the basis for the EHTP templates. The EHTP output includes Essential Lists for Human Resources, Drugs, Physical Infrastructure, and Medical Equipment. In addition, limited query and simulation capabilities ensure maximum benefit for health care planners.

lower levels of health care delivery address only the diagnostic component of a disease classification, but due to practical and other reasons involve a requirement to refer the patients to higher levels of care to address diagnostic and/or therapeutic components of clinical practice. In order to capture this difference of therapeutic and diagnostic elements for health care delivery, this artificial step has been included. No special codes are attached to this step.

Next is the CPT and/or ICPC coding. As mentioned above, a template of codes linking CPT to ICD is provided in the EHTP template database for guidance. The CPT codes and nomenclature (e.g., “62278, vaginal delivery only”) are given as shown in Figure 45-6. Multiple CPT procedures are again possible for a single Step and ICD Intervention. Again, linked to each procedure is another artificial element of the tree called the Techniques. This step is incorporated to ensure that all possible techniques may be captured to perform a single Procedure. Linked to the Techniques are the health care technologies (e.g., medical devices, drugs, human resources, and health facility), as described previously.

For each of the health care technology propriety databases, collateral information is collected. For example, for medical equipment, data on life expectancy, user training, complexity, criticality for the procedure, and maintenance requirements are collected. For the purposes of this chapter, not all details of this information will be discussed.

Implementation

Scope

The nature of implementation is slightly different for the different levels of health care delivery.

At the national level, the EHTP mainly will be used as a planning tool aimed at identifying the relationship between health care technologies and health care interventions. At lower levels of health care, the EHTP will focus on identifying resources with particular emphasis on simulation and comparing different health care delivery scenarios. Economic evaluation and cost analysis can identify hidden and recurrent costs, which typically include medical equipment costs such as installation, maintenance, user training, commissioning and decommissioning, consumables and spare parts, and purchase costs.

Adaptability of EHTP

The EHTP was developed specifically with the intention of being applied and implemented globally. The development of the EHTP template covering the entire spectrum of the ICD 10 codes contributes toward the country-specific implementation. Language adaptability has been provided, and most of the proprietary databases are available in various languages. For example, the UMDNS is available in English, Spanish, French, German, and Russian, while the ICD 10 is available in English, French, and Spanish, and the CPT in English and Spanish. (A French version of the CPT will be available within two years.) The EHTP database management system has been fully developed and tracks changes to the EHTP generic template ensuring proper management of the data-capturing process.

Implementation Process

Key activities for the EHTP implementation and information dissemination are given below and may be divided into three phases.

Phase 1

The first phase includes the training of trainers for EHTP implementation. Experts in the field of health care technology will be identified and will be invited to attend two workshops. These experts, once trained, will become the core group of trainers who will be responsible to support and guide the implementation, also monitoring and evaluation of the EHTP implementation both nationally and regionally. The curriculum for the training workshops includes hands-on training of the EHTP software, its methodology, and implementation strategies required to ensure successful implementation at the national level. Part of the first phase will be the development of training materials, guidelines, and facilitator notes. This documentation also will act as the reference material for the facilitators and trainers at the national level.

Phase 2

The second phase includes the identification of national counterparts from ministries of health or national institutions who ultimately will manage and facilitate the implementation of the EHTP at the national level. These individuals may be selected from within national ministries of health and finance and/or appropriate national institutions and will be responsible for all local management associated with the EHTP implementation. These national counterparts will attend two training workshops to familiarize themselves with and strengthen their understanding of the EHTP methodology and use of the EHTP software. In each participating country, infrastructure will be provided in order to support and manage the EHTP implementation. It will include the EHTP software, computer system and peripherals, modem, and documentation.

Phase 3

The third phase includes modification of the EHTP generic template database.

The EHTP software is provided to each participating country with a generic EHTP template containing data on such details as medical device costs, human resources, and drug requirements. These templates must be modified to reflect the requirements and

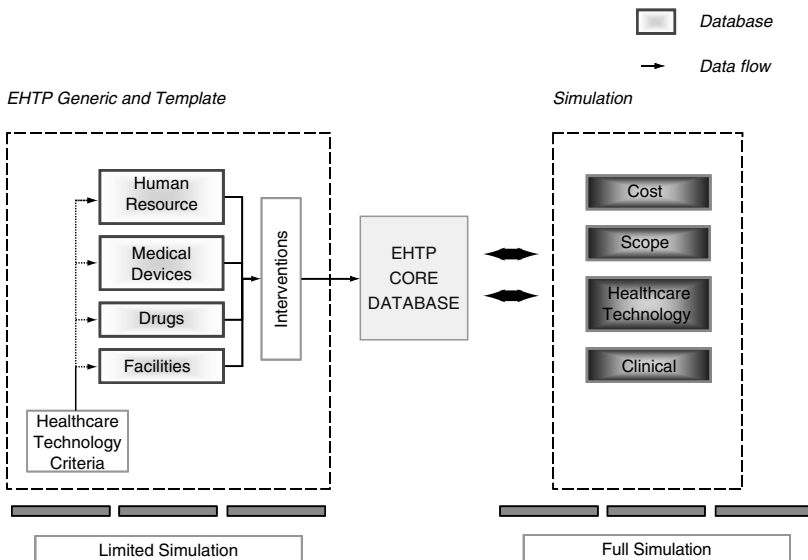

Figure 45-4 The EHTP system overview. The EHTP generic template database (shown on the left) is used to modify, edit, and append changes to the EHTP providing the basis for country-specific databases. These changes, which may include country-specific modifications, are stored in the EHTP core database (shown at the center). This core database is accessed by the simulation tools (shown on the right), which embrace all of the simulation and querying functionality of the EHTP package.

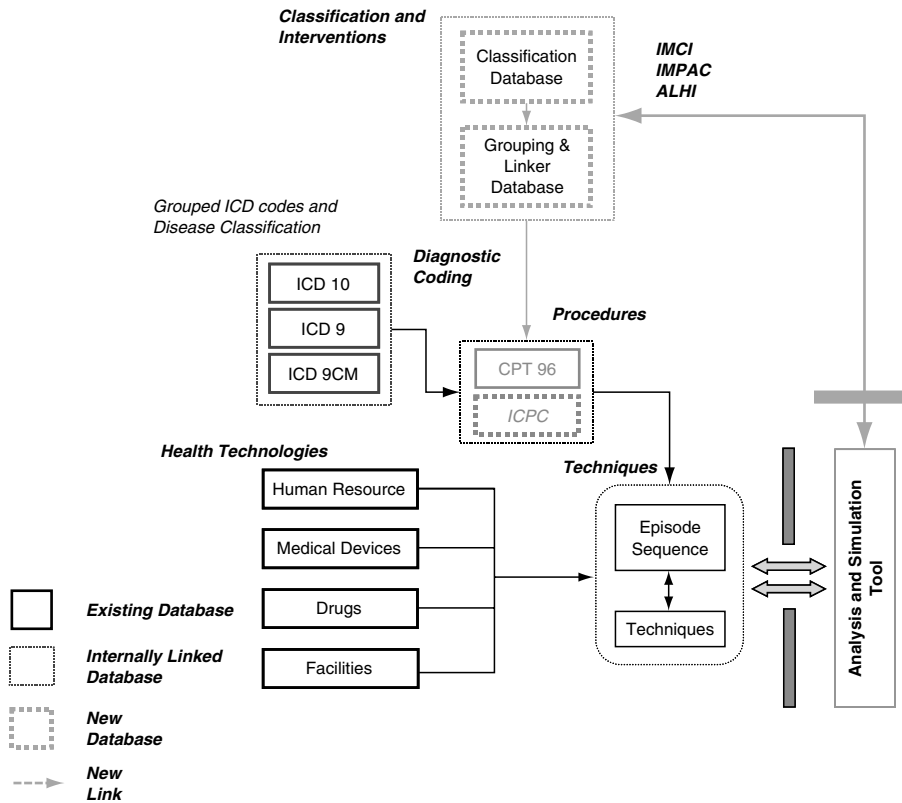

Figure 45-5 The EHTP template system overview. The EHTP health care technology databases (classification of diseases (ICD) and interventions of the special health initiatives) are linked to the CPT and International Classification of Primary Care (ICPC) procedures databases. A procedure sequence capability has been added to ensure logical flow of procedures. The limited simulation and tools component is shown. An additional link between the simulation tools and the special health initiative database has been implemented to ensure that grouped interventions, as defined in the special health initiatives packages by the WHO, can be simulated.

realities of the specific country of implementation. This process of modifying the EHTP templates will be managed by the national counterparts, as described in Phase 2, above.

The national counterparts will organize numerous workshops during the first year of implementation. Each workshop will address a specific clinical specialty (for example, anesthesiology, pediatrics, or mother-and-child health care), and local medical specialists and experts will be able to modify the EHTP generic template to reflect local conditions. The modified EHTP template then will be incorporated into the country-specific EHTP package at the national level and will form the basis of the health care technology management planning tool for decision-makers.

Information Promotion and Dissemination

This phase will be an ongoing activity for each participating partner country and its collaborating partners. Results and other outputs of the EHTP implementation will be disseminated at scientific meetings and meetings of regional stakeholders and will be provided to regional governments for their consideration.

In collaboration with the WHO, a number of countries have been selected for EHTP implementation. These include Namibia, Mozambique, South Africa, Estonia, Russia, Nepal, Sri Lanka, and Cuba. Numerous presentations have been made to the appropriate authorities in the selected countries. The benefits and implications of the EHTP have been presented and highlighted. The identification and selection of the Trainers of Trainers has been completed, and the first workshop was presented in Geneva and South Africa in 2000. The implementation schedule for the selected countries has been finalized, and resource material (e.g., facilitators' manuals, implementation notes, and guidelines) have been developed.

EHTP Justification

The burden of disease has become an integral component in the setting of health priorities for many countries. The concept of disease burden is well established and has been documented extensively. Many organizations have assisted governments in identifying their burden of disease, and the concept is now well entrenched and linked to economic, quality, and disability aspects qualifying health care delivery.

The processes of priority setting, health policy formulation, and the development and implementation of health initiatives that are specifically tailored to address disease burden are vast (in their own right) and therefore are not addressed in this chapter. The formulation of many health initiatives aimed at addressing specific diseases and illness (i.e., IMCI, IMP, and AC) and promoting well-being (i.e., Essential Programme on Immunization [EPI]) have been well documented and supported internationally. Guidelines and significant support infrastructure have been developed at the country level with the support of the United Nations agencies and governmental and non-governmental organizations. Globally, the majority of governments have adopted and

incorporated these health initiatives into their own action plans to address the prevailing national disease burden.

It is the realization and implementation of the above-mentioned health initiatives into existing governmental structures that has proven to be most difficult. The vertical nature of these health initiatives and the rigid hierarchy of government services indeed prevent effective integration and highlight the precarious situation that health care planners and decision-makers face.

The difficulty of implementing these health initiatives is partly explained by the nature and application of these health initiatives. Figure 45-7 shows a representation of the relationship between the health systems' requirements for various levels of health care delivery. At the managerial level (health systems-orientated), substantial managerial and planning component are required in order to achieve the objectives. However, as we descend through the layers of health care delivery, the technical (case management or patient-orientated) component becomes more important and the managerial aspects are reduced.

At the regional level, patient-orientated aspects of health delivery are often addressed exclusively by clinical experts while planners and decision-makers in dedicated but separate institutions address managerial and planning issues. This aspect of separating the patient-orientated and health systems-orientated planning and service provision elements is generally observed up to the district level. For health care delivery levels below the district level, both health systems and patient-orientated functions are usually allocated to one individual (typically a nurse or an appropriate health care professional with a clinical background), often resulting in the omission of management and planning components at levels below the district level. This fact significantly impacts on the effectiveness of service delivery and on the overall implementation of the above-mentioned health initiatives as management information and planning detail at the technical level (case management) is not incorporated into systems planning. The practical consequences of this are often reflected by the absence of sufficient drugs, medical devices, and human resources at clinics, health care centers, and, to a lesser degree, at district-level facilities.

This failure at higher levels of service delivery to provide direct support and guidance with regard to the management component concerning the allocation of resources is one of the most important shortcomings of the implementation strategy for most health packages and other initiatives.

Improvement of resource allocation cannot be addressed effectively if, in addition to the above-mentioned shortcomings, no mechanism exists to ensure that the planning process at the managerial level knows the requirements at lower levels of health care delivery. This feedback loop in Figure 45-2 is essential for the planning process.

The EHTP provides a unique method by overcoming this shortcoming concerning the management and technical components of health care delivery. The EHTP matrix provides a unique mechanism enabling the management level to identify resource requirements at the technical level (case management), particularly as it provides a platform to simulate patient-load and disease-profile scenarios.

One further shortcoming is the assumption that resources are allocated with specific reference to the health initiatives (e.g., the allocation of resources for health care technologies, drugs, infrastructure, and staff for special health initiatives like the IMCI

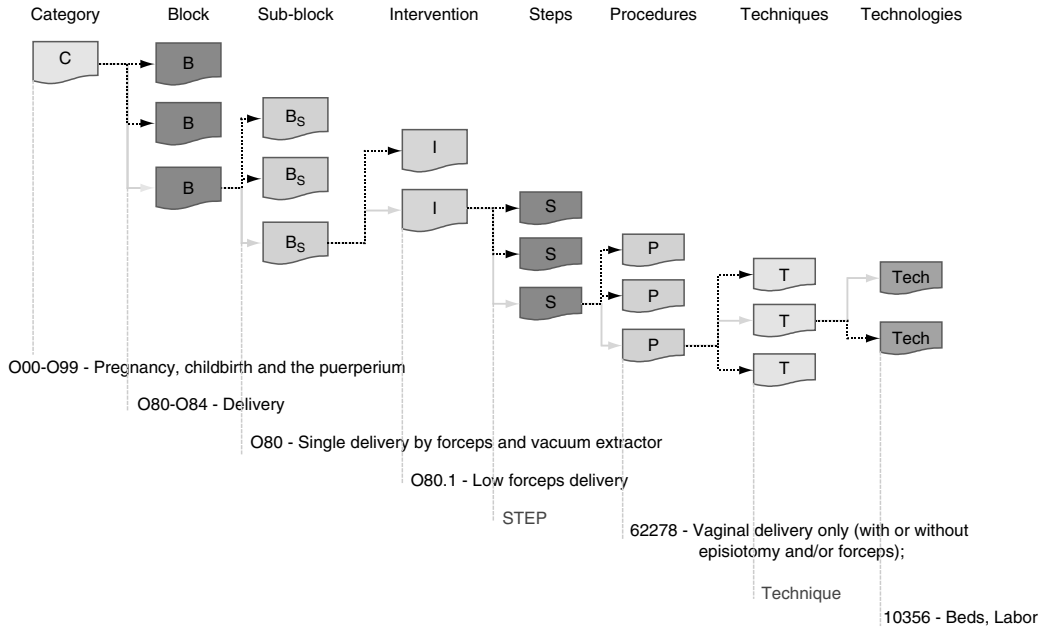

Figure 45-6 Linking of the International Classification of Diseases (blocks C, B, Bs, and I) to procedure (P), and technologies (Tech). An example from pregnancy and childbirth is given below the tree structure. C represents the disease classification; B represents the disease block; Bs represents the block subset; I represents the intervention; S represents the step; P represents the procedure; T represents the alternative techniques per procedure, and Tech represents the technology (e.g., medical devices, drugs, human resources, and health facility).

program). In reality, however, government ministries are funded at the functional and departmental levels, and specific and dedicated health initiative resource allocation is thus very difficult and often virtually impossible.

This process of priority setting, health policy formulation and implementation, and the development and specification of the Essential Health Packages often receives attention at the highest national level. Often more resources and political support ensuring some form of success support this process. The implementation of the Essential Health Packages, however, does not always receive the same importance from both the political and financial level, and therefore the implementation often fails or is implemented suboptimally.

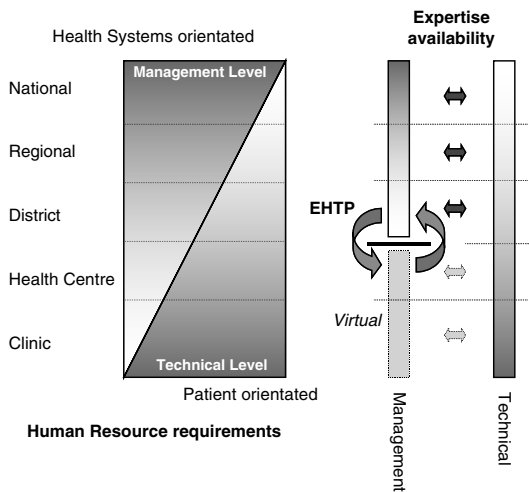

Figure 45-7 The EHTP matrix provides a “virtual” management environment by providing detailed information to health managers at a technical level. The EHTP also ensures that management information from a higher level of health care provision is reflected within this virtual management environment and thus ensures that the information exchange between the technical and management levels is maintained. (See horizontal arrows.) The figure on the left indicates the management/technical requirements associated with each level, of health care. Below the district level, however, the management capacity of health care providers in many countries is significantly reduced due to the exclusively technical nature of staff. The black line represents this barrier whereby the circular arrows represent a bridging of the EHTP gap.

Not only are political and financial resources required for the successful implementation of the Essential Health Packages, but also accurate and specific information is needed. The inability of lower levels of health care delivery (e.g., the district level) to provide meaningful information feedback to central and national ministries also contributes toward this suboptimal implementation of the Essential Health Package. Often the management and service provision details, which are applicable at the district level, are not known at the central level, which might lead toward the inappropriate design and implementation of the Essential Health Packages. Other reasons for the suboptimal implementation include:

- Lack of the implementation funds
- Shortage of skilled personnel
- No monitoring and evaluation of implementation process
- Omission of guidelines
- Inability to detail the realities of lower health care delivery levels

It is specifically this barrier that the EHTP aims to overcome by providing detailed information to decision-makers, thereby ensuring that the Essential Health Package is translated into a realistic package, permitting practical application.

The operational focus of the EHTP is shown in Figure 45-8. The EHTP specifically focuses on overcoming the barrier, as described above, and ensuring that a benefit is derived both at the district level and at the central level via the feedback loop, as indicated.

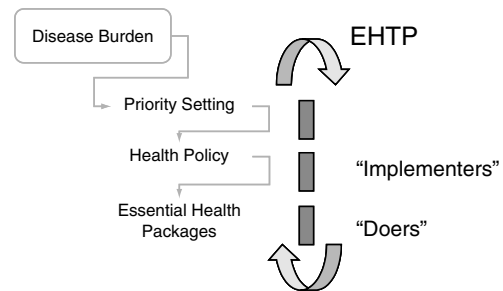

Figure 45-8 In the delivery of health care, the development of Essential Health Packages through prioritizing interventions to address disease burden is well known. However, the integration of these “vertical” Essential Health Packages into existing health care programs is extremely difficult due to the rigid resource-allocation mechanism. Therefore a barrier exists between the planning and the implementation of these Essential Health Packages. The EHTP provides a mechanism to bridge this barrier and ensures that information is both provided to and received from the implementation process.

EHTP Matrix in the Support of Health Care Technology Management and Planning

The development of the EHTP matrix provides health care planners and decision makers with a unique tool supporting the process of resource allocation. In addressing the burden of disease and the subsequent development of Essential Health Packages (through priority setting), the issue of allocating resources is paramount. Although resource allocation may be categorized and even associated at a macro level to disease burden, the allocation of actual resources within executing agencies such as ministries of health are exclusively linked to human resources, capital, and recurrent expenditure. The decision making process therefore becomes confronted with a complex problem of allocating resources to existing and known health care technologies (e.g., medical devices, human resources, drugs, and infrastructure) and trusting that these health care technologies when bundled into action and together with health care programs will address and alleviate the prevalent disease burden. The absence of specific information of the effect that these health care technologies have on the management of disease burden and how this comes about might be the weakest link in the current health care technology planning process. The EHTP, through application of its matrix, therefore provides a fundamental component in the planning process and uniquely addresses the shortcomings mentioned above. In addition, the EHTP also provides a qualitative method through which resource allocation (specifically health care technologies) can be evaluated and assessed.

The identification and application of this matrix therefore supports decision makers in prioritizing which health care technologies (medical devices, human resources, drugs and facilities) must be supported to guarantee the effective implementation of health care interventions to address identified diseases. In particular, the ratio of recurrent cost versus capital investment within any given health care system can be determined within the context of addressing the identified diseases.

Link to Other Health Initiatives

One of the criteria in the formulation of the EHTP concept was that the point of origin should be able to tie into existing health planning and -management tools and indicators. This requirement was seen as fundamentally important in ensuring continuity between macro and micro aspects of health care delivery.

Disease burden has been recognized as a fundamental and important indicator in any health planning process and has found universal application. The inherent macro nature of the disease burden indicators clearly makes this indicator unsuitable for the process of linking health care technologies to known and applied health service indicators. However, disease burden indicators have been linked to disease classifications and diagnostic codes, thus making the disease classification and codification an ideal point of entry for the EHTP.

The ICD, in their own right, have found universal application, and many nations have standardized on one of the versions available. The latest version, ICD 10, is a revision of the widely distributed ICD 9 codes, which classified the majority of curative diseases. These codes, which have been developed under the auspices of the WHO, now also include specialty areas such as neurology, mental health, dentistry, and anesthesiology. International codes on primary health care (ICPC) have been developed as well; however, they have not found the same acceptance as the ICD 9 and 10. This has resulted in many nations developing their own primary health care classifications and codes, preventing accepted classification. This issue makes the link between the EHTP matrix and the primary health care classification far more difficult.

EHTP Advantages

EHTP Application

The EHTP finds its principle application in the planning and management of health care technologies. The management of medical devices, human resources, drugs, and facilities is multidisciplinary and requires attention at various levels of the health care system. The scope and complexity of the planning and management process of health care technologies are different for the various levels of health care. For example, the range and even the level of complexity of medical devices and skills required at the district level is vastly different from that required at the regional or central level. The degree of effort to manage these technologies therefore also differs from level to level and requires a unique approach for each level of health care delivery.

The management of these health care technologies can best be described by its life cycle. The life cycle of health care technologies can be categorized into three distinct phases: Provision, acquisition, and utilization. The EHTP supports all three phases by providing both quantitative and qualitative information, but also it provides a unique opportunity to simulate various conditions and effects for different health care scenarios. Within this context, the EHTP has found a unique application for which the main areas of use are summarized below.

The EHTP:

- Provides a map and link of all international disease classifications to promotive, preventive, and rehabilitative procedures
- Provides the essential health care technology elements (e.g., medical devices, human resources, drugs, and facilities) required to reduce the burden of disease
- Provides a list of all health interventions and typical time requirements per intervention for each disease classification
- Provides dynamic Essential Lists for specific levels of health care delivery and/or disease classification. These include medical equipment lists, human resources lists, essential drug lists, and essential facility lists
- Provides a qualitative method of determining capital and recurrent costs of medical devices per disease classification

- Provides management data on medical devices, including technical classifications, maintenance, and utilization information
- Provides economic data on human resources, facilities, and drugs
- Simulates the costs of medical devices, human resources, and drugs for all disease classifications, interventions, and clinical procedures for various levels of health care
- Simulates the interdependencies of medical devices, human resources, drugs, and facilities for various health interventions and scenarios
- Provides a reference to health care technology audits, existing standard equipment lists, and staffing requirements

Essential Equipment Lists

The static nature of the standard equipment lists makes them less attractive in the planning and allocation of resources. Many standard equipment lists have been developed before and have been modified repeatedly, but the shortcomings of these lists are not really addressed. The development of the EHTP provides a number of advantages (given below) as compared to the standard equipment lists.

EHTP provides a dynamic Essential Equipment List. The link between use of medical devices and health interventions is uniquely identified and is therefore modifiable. Changes to either the health intervention (which includes changes to clinical practice) or health technologies (which includes medical devices, human resource skills, or techniques) can be easily incorporated into the Essential Equipment Lists, which are based on the EHTP methodology.

The fact that all health interventions have been mapped to their respective health care technologies also provides an additional benefit. For example, the addition of new health care technologies to the Essential Equipment Lists can be evaluated by assessing their utilization rate within a package of health care interventions and determining the other health interventions that could benefit from the introduction of this new health care technology. Similarly, shared human resources and skills can be identified and easily evaluated.

Changes in disease patterns and epidemiological differences within a regional or country can be incorporated into specific and focused equipment lists that are derived from the EHTP. In addition, the development process and effort associated with formulating standard equipment lists is greatly reduced, thus allowing valuable resources time to be applied to other activities.

A fundamental shift in the development of the Essential Equipment Lists has also been achieved through using the EHTP methodology. The static nature of the standard equipment list determines that a limited number of experts normally formulate these lists. In comparison, the Essential Equipment Lists derived through the EHTP methodology have a much larger expertise base because each disease specification and its resulting health intervention is addressed by an expert or panel of experts in that field. The advantage of this process is that each medical specialty has input in the development of an appropriate health care technology list without prescribing or influencing the lists formulated by other medical specialties.

Requirements at any given health facility as a function of human resources, medical devices, and drugs also support improved decision making. This issue in particular is important because facilities in the past have been treated independently and as being quite distant from health interventions and the prevailing disease burden. The development and implementation of facilities has a significant budgetary implication for any health care system. Independent and dissociated physical-infrastructure planning clearly has a negative impact on the effectiveness of health care delivery. In particular, recurrent and long-term liabilities of the physical infrastructure planning process are ignored in the formulation of standards and norms associated with facility planning. The availability of the Essential Facility Lists based on the inter relationship among facilities, medical devices, drugs, and human resources therefore provides a significant improvement in the health care technology planning process and assists decision-makers in gauging and defining an appropriate level and scope of physical infrastructure.

Scientific Basis of EHTP

One major concern in the development and implementation of the Essential Health Package was that much of the planning required quantitative data. Rapid changes in health care technology trends, clinical practice, disease burden and profiles, and economic realities have made health care technology planning more challenging than ever before.

Evidence has shown that planning and decision making based on past trends seldom correlates accurately with future situations for systems as complex as those in the health sector. Planning for the future therefore requires significant emphasis to be placed on providing solutions that are based on evidence and that are scientifically defensible. The EHTP methodology has incorporated this trend by providing scientifically sound methods of relating health care technologies to health interventions without losing sight of the overall objective.

The need to determine the impact of health care technologies on health care delivery also forces us to consider a scientific basis that can quantify this impact. During the last decade, many donor agencies have been confronted with the fundamental question of what the impact is of the health care technologies that they have provided on the recipients' health care system. The lack of any proper scientific basis to determine this impact forced these agencies to use empirical evaluations and assessments to determine the effect within a focused and time-limited survey.

Promotive, Preventive, and Curative Health Care

The EHTP methodology allows the linking of any health care intervention to its relevant technologies. Currently the curative health care component has been incorporated into the EHTP, based on the immediate availability of the ICD. However, promotive and preventive health interventions form an important component of the overall health delivery package of any nation, and provision therefore has been made to incorporate these into the EHTP.

Dynamic System

Changes in disease profiles at all levels of health care suggest that the Essential Health Package needs similar changes to address such changing disease profiles. The static nature of Essential Health Package seldom is in the position to address any rapid changes—especially those in disease profiles.

Due to the static nature of the specialized health initiatives as part of the Essential Health Packages and the enormous effort that is required in order to implement these packages, even minor changes to the Package require enormous effort to ensure that these changes are applied throughout the health care system. These changes and the untested and unevaluated impact and long-term effects have made the implementation of the Essential Health Packages such a difficult task.

The EHTP addresses this static nature of the Essential Health Packages, by providing the platform of relationships between service interventions and their required health care technologies. Therefore an addition or omission of any health intervention from the Essential Health Package can be evaluated and assessed rapidly without having to re-evaluate the entire EHTP package.

Simulation of Interventions

The EHTP also provides a useful platform to simulate the cause and effect of health care technologies concerning health care interventions and disease burden. The nature of the EHTP matrix determines that all health technologies are linked to the associated health interventions, providing a useful tool to determine the effect of health technologies upon each other and upon health care interventions and the burden of disease. For example, the omission of a medical device will reveal the health technologies (e.g., other medical devices, drugs, human resources and facilities) that will be affected by this omission. In addition, all medical and nonmedical procedures and interventions that will be affected will then become known.

Clinical Procedures and Clinical Practice

The rapid development of new medical devices, knowledge, and clinical practice has resulted in significant changes in the delivery of health care. The enormous scope of new medical devices reaching the markets each year, the impact that they have on clinical practice, and the burden that they have created for health care planners and decision-makers alike have necessitated a reinvestigation of current planning procedures and policies. It is apparent that the magnitude and complexity of new technologies that have been introduced into the health sector no longer can be managed by traditional, existing managerial capabilities.

Coupled with the increasing rate of technological advances, the increased application to specialized health and medical areas and the increased need for support technologies all have increased the need for a new health care technology management paradigm. Existing health care technology management tools, such as the static equipment lists, no longer are able to incorporate these changes fast enough to provide a useful management tool.

In addition, the multidisciplinary nature of the technical advances, which span the spectrum of curative, preventive, and promotive health care, requires the input of a team of experts in the planning process, to ensure that all areas of health care provision are covered. Reality dictates that a continuous input from experts in the planning process cannot be maintained. The EHTP partially addresses this problem through its multidisciplinary approach. The EHTP matrix also allows simultaneous and independent modification and alterations without affecting the availability of the management tool.

National Implementation

In addition, national implementation has the advantage that local experts can oversee and perform modifications of EHTP template, thus ensuring that local conditions that reflect economic realities, clinical practice, skills base, and social and political considerations can be incorporated into the EHTP. Basic and essential services can be determined within the constraints of the budget and may be included as part of the EHTP implementation.

Definition and Delineation of Terms

The definition of “health technology,” used by WHO, includes devices, drugs, medical procedures, and surgical procedures, and the knowledge associated with these, used in the prevention, diagnosis, and treatment of disease, as well as in rehabilitation, and the organizational and supportive systems within which care is provided (Broomberg and Shisana, 1995).

Health care technology therefore includes all medical equipment, devices, and consumables, as well as the organizational, support, and information systems used at all levels of health care delivery. Medical and surgical procedures, especially those that make substantial use of health care technology as defined, are included by implication.

Health care technology is therefore an umbrella term for a family of systems, techniques, and physical items used in health care delivery.

This definition also incorporates:

Organizational and physical infrastructure, including health facilities and buildings; their installations and plant; energy sources and water and gas supplies; and supportive and logistical systems, whose components are supply systems, information systems, communication and transport systems, and waste disposal systems.

The health care technology life cycle is considered to consist of three phases: Provision, acquisition, and utilization, each of which can be subdivided as follows: Provision includes assessment of needs, research and development, testing, manufacture, marketing, technology transfer, and distribution. Acquisition includes technology assessment and evaluation, planning, procurement, installation, and commissioning. Utilization includes operation, user training and support, maintenance and repair, risk management, assets management, and decommissioning. The first phase falls within the domain of industry, while the last two are generally the responsibility of national health systems and health care providers.

Impact Analysis

Thomas M. Judd

Director, Quality Assessment, Improvement and Reporting,
Kaiser Permanente Georgia Region, Atlanta, GA

There are many issues contributing to health in developing countries. Availability of appropriate health technology (HT) resources is one principal factor. The World Health Organization (WHO) defines HT resources as including human resources, pharmaceuticals, equipment, and facilities. Proper management of HT can assist in meeting health needs by addressing supportability and sustainability of HT resources. Integrating HT resource planning and management as they support best clinical practices remains a challenge. This has been demonstrated through several relevant case studies in which clinical engineers have directed or assisted HT management (HTM) activities providing cost benefits, and improved quality of care and patient outcomes.

Effects of Health Care Technology Management

Economics and Health

Developing countries typically spend about 7% of their Gross Domestic Product Purchasing Power Parities (GDP PPP) on health. For example, U.S.\$2 billion out of U.S.\$28 was spent in recent years in a Latin American country, or \$240 annually per person with per capita annual income of about U.S.\$2,000 (Judd, 1997). Ideally, the investment in health would address the major health needs, would assist in improving health status, and would improve life expectancy (LE). Major needs and disease prevalence for the example include cardiovascular disease and cancer for adults, and intestinal, nutritional, and respiratory conditions for infants and children under five years of age. Interventions typically require the use of various health facilities and medical devices. Economic growth also affects LE. This growth is influenced strongly by availability of physical resources, knowledge resources (physical, technology, and human), and economic liberty (sociopolitical systems).

Impact of HT on Health

Proper use of HT resources can reduce risk of disease, shorten duration of disease, improve access to care, improve patient functional status, contain health care costs, and lower intervention risk. Technical innovation in health care is a relatively new phenomenon, providing a wide range of positive treatments in the prevention and cure of illness.

Health organizations as “socio-technical systems” are highly dependent on the human factors that bridge the people and other HT resources used in treatment. The discipline of clinical engineering (CE) has emerged in the last quarter of the 20th century, to assist health professionals in various health settings with the effective use and management of a vast array of medical devices, processes, and health facilities that are currently available. CE is a subspecialty of biomedical engineering that is devoted to the application of engineering methods and technologies in the delivery of health care. HTM addresses challenges in HT planning, procurement, and management, as shown in Table 46-1.

Health System Structure Issues

Health care typically is delivered through both the public and the private health sectors. Local, provincial, and national health authorities interact in any country. Empowering these authorities should be one objective of health care reform. Typically, the central government’s role in improving health is largely in standards-setting and fiscal control through, for example, a ministry of health (MoH). As a new health care model is formulated in a country that implements reforms entailing increased investment in health technology, development of increased HTM capability is required. HTM can assist in overcoming waste and the “iceberg” syndrome, as shown in Figure 46-1. This effort requires the MoH’s support in recognizing and implement HTM to support best clinical practices.

A health care system that falls victim to the iceberg syndrome, largely as a consequence of inadequate HTM, typically experiences problems and corresponding wastages, as shown in Table 46-2.

Table 46-1 Elements of health technology management

Financial evaluation Equipment planning Architectural Coordination Engineering support	Bid analysis Selection Purchasing Financing	Management systems and software Warranty monitoring Service contract monitoring Training management Risk management and quality assurance CE department procedures ISO 9000 quality documentation

Assessment of Impact

In order to improve performance of health systems, health indicators are needed in order to measure the effect of HTM practices. Such effects of HTM practices include those listed below:

- DALYs (disability adjusted life years, global burden of disease) assess patterns of illness and injury with units that take into account premature death and impact of disabilities. Better HTM improves DALYs.
- Better HTM improves HT resource planning for unmet regional health and resulting HT resource needs.
- Patterns of health expenditures on inappropriate, wasteful, or potentially harmful services, reducing overuse.
- Cost-effective care providers and practices (e.g., evidence-based medicine (EBM)), and increasing underused practices.
- Interventions that improve safety and quality-of-care processes and outcomes in all health care settings.

Quantitative Evidence of HTM Impacts

The following quantitative evidence of the impact of HTM has been observed with medical devices, health facilities, and health delivery system processes (Judd, 1998).

HTM Case Studies

USA—Medical Equipment Management

HTMs for equipment resources were conducted in seven geographic areas with 21 hospitals, whose average size was of 225 beds (David and Judd, 1993). The seven HTM teams of 10 technicians each provided equipment management services to a wide range of medical equipment including general biomedical, laboratory, and radiology equipment for each three of these hospitals. Three years after program start-up, there was a 30% cost savings for internal equipment management versus external manufacturer

support, primarily due to a 50% reduction in radiology maintenance costs. For example, there was \$540,000 in support costs at baseline of which \$340,000 was for radiology equipment; after three years, there was a \$170,000 reduction after all costs were taken into account.

Success for internal equipment maintenance led to involvement in other HTM activities such as the following, accomplished by the staff:

- Moved and reinstalled X-ray rooms.
- Upgraded CT scanner systems.
- Were key decision-makers in new acquisition, and assisted in improving equipment-replacement decisions.
- Led a process that resulted in standardization of medical imaging equipment.
- Improved quality and cost-effectiveness of high-cost radiology equipment consumable items (e.g., glassware).
- Developed processes to identify risk-related trends in equipment use and maintenance.
- Became more widely involved in related facilities planning issues.
- Improved technology planning based on equipment utilization and uptime indicators.

HTM Workshops

The American College of Clinical Engineering (ACCE), World Health Organization (WHO), and Pan American Health Organization (PAHO) have conducted Advanced Health Technology Management Workshops (Judd et al., 1991). The effects on medical equipment HTM demonstrated in the United States above have been partially extended to national health care technical services (HCTS) in developing countries. The process of transferring these kinds of results has been led by WHO Department of Health Services Provision (WHO/OSD), which has worked from the mid-1980s to the present with the global clinical engineering community through a series of international workshops. (See Chapter 70.) ACCE began international HTM workshops in partnership with WHO and PAHO in 1991, which, to date, have resulted in training key equipment HTM leaders on five continents and in 75 countries. Principal global areas that had been served prior to that time include Latin America (1991, 1994, 1997, and 1998), Eastern Europe, and the former Soviet Union (1993), the People’s Republic of China (1995), the Middle East (1996), Russia (1999, 2000), and Sub-Saharan Africa (1999). The ACCE website <http://www.acenet.org/InternationalCommittee/index.html> describes past workshops and locations dating back to 1999.

ACCE developed a syllabus for these workshops, under contract for WHO (Dyro et al., 2003). The following outline demonstrates HTM training issues for equipment and facilities in developing countries.

- Section 1 Introduction
 - 1.1 Advanced Clinical Engineering Workshops
 - 1.2 Health Care Technical Services

- 1.3 Guide for the Formulation of a National Health care Equipment Policy

 - 8.2 Developing a Budget

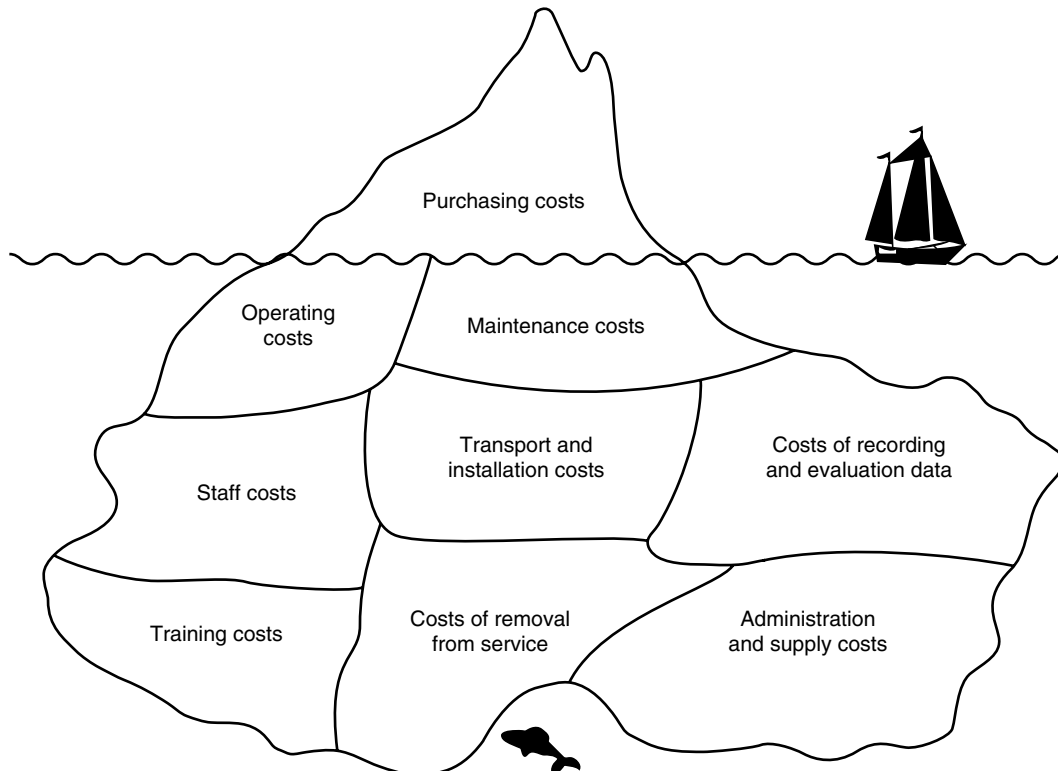

Figure 46-1 The iceberg syndrome in life-cycle costs of health care equipment.

Table 46-2 Problems and corresponding wastages as found in many developing countries

Problem	Waste
Inability to correctly specify and foresee total needs when tendering and procuring equipment	10–30% extra cost
Purchase of sophisticated equipment that remains unused due to lack of operating skill and technical staff	20–40% of equipment
Extra modifications or additions to equipment and/or buildings unforeseen at the initial tender stage due to lack of staff expertise	10–30% of equipment
Maltreatment by operating and maintenance staff	30–80% of lifetime
Lack of standardization	30–50% extra spare parts cost
Down time due to inability to use or repair, or due to a lack of spare parts or accessories.	25–35% of equipment

Table 46-3 Quantitative evidence of HTM impacts (Judd, 1998)

System	Cost (or time) savings
<i>Medical devices</i>	
Maintenance	20–30%
Reduced investment through planning	10–20%
Reduced development time for acquisition specifications	(2–4 weeks)
Appropriate HT introduction	10–90%
User training reducing maintenance	10%
<i>Health facilities</i>	
Reduced investment through planning	10–20%

Section 13 Summary of Workshop Goals and Objectives

13.1 Summary of Workshop Goals and Objectives

Africa—Medical Equipment Management

The following case studies were presented at the ACCE HTM Workshop for Sub-Saharan African countries in Cape Town, South Africa, in November 1999.

Ghana—Juergen Clauss, FAKT, 1999

- Forty of 124 hospitals are assisted by Ministry of Health (MoH) HCTSs, and another 15 hospitals are assisted by two nongovernmental organizations' HCTSs and three private companies.
- Health sector reform is underway and includes contracting of health services to public and private providers for a variety of health resources, including equipment and facilities.
- Equipment management and technical training courses are provided by US NGO International Aid.

Tanzania—Juergen Clauss, FAKT, 1999

- Seventy-five of 195 hospitals are assisted by the MoH HCTSs, and another 60 hospitals are assisted by NGO HCTSs. There are several MoH HCTSs in different regions, as well as three private companies and an equipment HTM training school.
- Health sector reform is underway, however there is no HT policy process at this time. There are various donor investment programs at work.

Senegal—Roger Schmitt, GTZ, 1999

- There are six HCTSs in six cities, with a focus on regional and national hospitals (between 150 and 400 beds in size).
- Conclusions of several studies in the 1990s: HCTSs with up to two technicians and two craftsmen are economical. However, equipment preventive maintenance is irregular; there are equipment procurement problems; health-reform decentralization complicates improvements in HTM programs; and often donor activities are not helpful to the development of HCTS.

Kenya—John Paton, GTZ, 1999

- There was a study of medical equipment spare parts that focused on specifications, procurement, storage, distribution, and finance issues. The study initially identified 10–20 more urgently needed parts that were purchased with EU funding and distributed to HCTSs, where they were quickly used. Effectiveness of repairs was to be studied next.
- A comprehensive list of needed parts is being provided as a result of establishing equipment standards, including parts distribution and storage; establishing a procurement system; and ensuring long-term financing to promote sustainability.

HTM in Preventive Care

Proper preventive screening with appropriate HT resources leads to better patient outcomes (Judd and Painter, 2000). Equipment management should be focused in the areas that are known to support the best clinical practices, as shown in Table 46-4. Resources and their impacts are cited in evidence-based prevention guidelines, as shown below:

Breast Cancer Screening

Impacts

- Breast cancer is the most common cancer and major cause of cancer death in women aged 40–69; the American Cancer Society estimates over 180,000 new invasive cases annually and over 40,000 deaths.
- Appropriate mammography can reduce mortality by as much as 30%.
- Approximately 75% of women with breast cancer have no identifiable risk factors.

Key Aspects of Evidence-Based Practice Guidelines

- Ages 40–50: Offer yearly, with discussion of potential risks and benefits
- There is a higher false-positive rate (lower positive predictive value) for screening mammography for women under age 50. This results in calling patients back to repeat films; additional studies, including biopsies; and anxiety for the patient.
- Ages 40–65: Conduct mammograms yearly; little risk from accumulated radiation exposure due to calibrated low doses from equipment from ACR accreditation.

Table 46-4 Clinical practices and primary technology for screening for breast and cervical cancer

Clinical impact	Primary technology involved (devices, drugs, processes)
Breast cancer screening	Radiology Mammography
Cervical cancer screening	Laboratory cytology

Cervical Cancer Screening

Impacts

- Cervical cancer affects approximately 13,000 women in the United States annually, with approximately 4,600 deaths annually, and is the leading cause of cancer death among women aged 35–54.
- Between 1955 and 1992, the number of deaths from cervical cancer declined by 74%. The main reason for this change has been the use of the Pap test to detect cervical cancer early.
- The five-year survival rate for early invasive cervical cancer is 91%. The overall (for all stages combined) five-year survival rate is 69%.

Key Aspects of Evidence-Based Practice Guidelines

- Ages 21–69: Repeat Pap smears every year until patient has three negative smears; subsequently, all women with an intact uterus should be screened every three years.
- For high-risk patients, or after total abdominal hysterectomy, screen annually.

HTM in Primary Care

Proper diagnosis and treatment with appropriate HT resources leads to better patient outcomes (Judd and Painter, 2000). Equipment management should be focused in the areas that are known to support the best clinical practices (see Table 46-5). Resources and their impacts are cited in evidence-based clinical practice guidelines as follows:

CAD

Impacts

- CAD is the leading cause of death and leading cause of premature, permanent disability in the labor force in the United States due to acute myocardial infarction (AMI).
- Use of revascularization procedures for treating CAD is increasing rapidly, such as PTCA and CABG.

Key Aspects of Evidence-Based Practice Guidelines

- Patient education focuses on cholesterol control, diet, exercise, and smoking cessation.
- Risk factor management focuses on smoking cessation, diabetes control, appropriate diet and exercise, treatment of depression as appropriate, and receiving appropriate immunizations, such as influenza and pneumococcal shots during the appropriate season of the year.
- Medications include antiplatelet therapy (aspirin), lipid-lowering agents, beta-blockers after AMI, possibly ACE Inhibitors for CHF symptoms, and antihypertensives for blood-pressure control.
- Goals: For patients with known CAD, have LDL cholesterol <130 mg/dl; ensure patients on beta-blockers immediately after AMI; and reduce variation in use of cardiac procedures; that is, reduce rates of repeat revascularization following angioplasty.

CHF

Impacts

CHF is the most frequent cause of hospitalization for people aged 65 and older, and it is rare among persons aged 45 years and younger. About half of patients diagnosed with CHF die within five years.

Key Aspects of Evidence-Based Practice Guidelines

Patient education focuses on managing symptoms and weight.

- Outpatient care management focuses on weight control, ensuring timely follow-up care depending on severity, ongoing laboratory screening, encouragement regarding smoking cessation, and appropriate immunizations.
- Medications include ACE Inhibitors or other vasodilator therapy.
- Goals include ensuring use of ACE Inhibitor therapy and ensuring outpatient follow-up after hospitalization to minimize re-admissions.

Asthma

Impacts

In 1998, approximately 83,000 Kaiser-Permanente (KP) members in the United States (5–44 years of age) had mild, moderate, or severe persistent asthma; prevalence was 2.8% among KP's pediatric population (5–17 years), U.S.-wide; 6.34% for ages 0–17; and 1.5% among KP's adult members (ages 18–44); U.S.-wide 4.49% for ages 18–44.

- National guidelines call for use of inhaled anti-inflammatory medications (preventers) in a ratio of at least 1.0 to use of inhaled beta-agonists (relievers) for optimal therapy to prevent asthma symptoms and flare-ups.
- Asthma-related hospital admissions or observation stays are generally considered to be preventable through effective outpatient management; well-informed providers and

Table 46-5 Clinical practices and primary technology for screening for coronary artery disease, congestive heart failure, asthma, and diabetes

Diagnosis and treatment	Primary technology involved
Coronary artery disease (CAD) secondary prevention	Laboratory -lipid profile; radiology—angiography Pharmaceuticals -beta blocker (use post-heart attack) (AMI)
Congestive heart failure (CHF)	Process: Multidisciplinary team approach with patient self-management tools; general devices—ECG; Laboratory—various; radiology—chest X-rays; Pharmaceuticals ACE Inhibitor use
Asthma	Devices: Peak flowmeters and spirometry; patient self management education and treatment plan; Pharmaceuticals: relievers/preventers
Diabetes	Laboratory: blood glucose, lipids, renal; patient self-management (glucometer) and education; Pharmaceuticals—various; outpatient management

patients are crucial for proper management; primary care providers need better education and support to ensure that patients have the knowledge and confidence to manage their conditions.

- Despite the fact that exposure to smoke is known to increase symptoms and to precipitate attacks, 13% of patients who responded to a national KP survey smoked.

Key Aspects of Evidence-Based Practice Guidelines

- Treatment schedules are stratified to severity of disease, from Level 1, intermittent (lung function greater than 80% of predicted), to Level 4, severe persistent (lung function less than 60% of predicted).
- Routine visits to primary care range from level 1, annually, to level 4, three per year.
- Routine screenings should include: Flu vaccine annually; office review of peak flows each visit; review of environmental triggers each visit; and update treatment plan and home management skills each visit.
- Diagnostic tests should include: Laboratory tests generally not helpful; radiology: chest X-ray at initial evaluation (pediatrics possible sinus X-ray); peak flow, spirometry and/or pulse oximetry tests.
- Treatment plan should include: Provider establish and agree on treatment goals with patient; ensure patient education; ensure patient self-management plan; review ongoing drug therapy with step downs if possible; patient conduct home peak flow monitoring three times daily, depending on severity, during flare-ups will allow patient to determine adjust drug use; care manager for sicker patients for closer monitoring and control.

Diabetes

Impacts

In the United States, 15.7 million people (5.9% of the population) have diabetes. An estimated 10.3 million have been diagnosed, but 5.4 million are not aware that they have the disease. Each day, approximately 2,200 Americans are diagnosed with diabetes. About 800,000 Americans will be diagnosed annually.

- Diabetes is the seventh leading cause of death in the United States, contributing to 198,140 deaths in 1996. This chronic disease has no cure.
- By afflicting 3%–5% of KP members, this condition typically has several comorbidities and is responsible for increased rates of AMI, stroke, kidney disease, and limb amputations, among other serious ailments.
- Health care costs are typically three times other than for nondiabetics. Optimal management of diabetes requires a system to identify patients, to deliver needed services, and to track consequences of care.
- An ongoing set of outcomes' measures can clarify which systems of care have the greatest benefits and which are the most cost-effective.

Key Aspects of Evidence-Based Practice Guidelines

- Treatment Team equals patient and the primary-care health care team (HCT). The primary-care HCT should address diabetes at every visit for any clinical problem. Diabetes is typically diagnosed by glucometer for two fasting plasma glucose tests or one random plasma glucose plus classic symptoms, and should have ongoing glycemic control laboratory testing. Care is stratified into three levels: Level 1: Glycemic control (HbA1c<7.1) and complications controlled; Level 2: HbA1c (7.1 – 8.1); Level 3 (>8.1).
- Initial-care activities and ongoing routine care by level with primary-care practitioner and other diabetes practitioners for ongoing glycemic control; as well as lipid management through ongoing laboratory tests; retinal screening; practitioner interactions for blood pressure control, foot exams, initial/ongoing education; renal screening through laboratory tests; behavioral health screening (25% have depression that affects adherence to guidelines); medication strategies; and outpatient-management plans.

HTM for Integrated HT Resources

The Essential Health Care Technology Package (EHTP) is a new methodology and set of tools that has been specifically developed to strengthen resource planning and technology management in health care (Heimann et al., 2003). It integrates management of all HT resources, including human resources, pharmaceuticals, equipment, and facilities. (See Chapter 45.)

The link between resources and the delivery of quality care is achieved by identifying all HTs that are needed to provide well-delineated promotive, preventive, and curative health interventions. Health interventions in turn are linked to the WHO International Classification of Diseases (ICD9, ICD10) and to other disease classifications (e.g., ICD9-CM). This mapping between HT resources and health care interventions is based on internationally accepted and recognized clinical practices. It is expressed in the form of a "matrix" or generic template whose elements include economic, technical, and other information, typically associated with acquisition of the HT resources and with their utilization in providing the interventions. This EHTP matrix is the basis of the EHTP methodology and tools, which are implemented in a suite of software packages. Each intervention is decomposed into progressively smaller components, down to procedures and their associated techniques. The decomposition uses the Current Procedure Terminology (CPT) of the American Medical Association. Over 350,000 links have been created between international classification of diseases and the CPT.

A unique and powerful feature of EHTP is the integration of epidemiological profiles and recognized clinical practices (such as clinical practice guidelines-CPGs) with the EHTP matrix. This allows advanced modeling and simulation for identifying economic and other resource requirements given varying scenarios of disease incidence and prevalence, and CPGs. Conversely, simulation can indicate epidemiological conditions that could be covered with available resources by using specific CPGs.

EHTP was developed over several years and was provided by the World Health Organization (WHO), Department of Health Service Provision (OSD), and Medical Research Council (MRC), South Africa, to WHO member states beginning in 2001, with the Kyrgyz Republic (Kyrgyzstan) Ministry of Health (MoH) requesting implementation beginning in 2002. Strengthening resource planning through effective management of health care technologies, EHTP achieved the following goals and objectives in Kyrgyzstan:

- Applied in the broad context of health systems development and reform, and thus aligned with (and possibly able to accelerate) present Health Reform efforts.
- Methodology and computer-based tool expected to measurably improve effectiveness, efficiency, performance, and quality of health delivery.
- Simplifies coordination of resources by central, district, and local health leaders and integrates management of these resources to allow more efficient distribution.

- Focuses on the country's disease burden, as defined by in the Kyrgyz Republic by MoH and the National Drug Council, who direct the national CPG development process.
- Uses best medical evidence to direct care at primary, secondary, and tertiary levels by selecting interventions or CPGs that are best fit to available financial resources and existing constraints.
- Methodology and tools may be dynamically updated with advances in medical technology.
- It has been piloted at three sites for primary- and secondary-level care in 2003 and is scheduled to be implemented nationwide in 2004. The pilot sites initially use EHTP to better manage five target conditions selected by MoH and pilot leaders: Hypertension (HTN), acute respiratory illnesses in children (ARI), iron deficiency anemia in pregnancy (IDA), brucellosis (BRU), and tuberculosis.
- Quality and cost indicators were developed; baseline results were measured in 2002, and follow-up results in 2003. Accountability measures to ensure that pilot understanding of key tool features will be conducted in 2003.
- Preliminary quality outcomes measured include those shown in Table 46-6.

EHTP Impacts

- Quality indicators show improvement across several key measures, both clinical process and clinical outcome related.
- Cost data are not comparable, as there has been no unified method for calculating costs within MoH hospitals and clinics. An MoH work group is addressing this issue.
- Use of EHTP as a resource planning through effective management of health care technologies has potential for significant improvement in quality in the Kyrgyz Republic and in many other developing countries.
- There are several other significant quality indicators that EHTP can address that have been identified in WHO literature; a sample of these indicators is shown in Table 46-7, with recommendations of ways in which the MoH in Kyrgyzstan could use them. Other indicators are noted at <http://www.who.int/health-services-delivery>.

Conclusions

Several models to assist developed and developing countries in creating effective health technology resource management show demonstrable impact on improved costs and quality. Some of the case studies highlight medical equipment management (HTM) best practices, and others demonstrate a broader view of HTM and its implications. Clinical engineers continue to contribute significantly to these efforts.

Table 46-6 Preliminary quality outcomes from EHTP implementation in kyrgyzstan

No.	Indicator	Baseline 2002			Re-measure 2003			Comments		
1.	Clinical Practice Guidelines (CPGs) approved by MoH & programmed in EHTP tool (have MH-validated lists of technologies used)	<ul style="list-style-type: none"> • 32 Primary level CPGs • 17 Secondary CPGs • 3 Tertiary CPGs 			<ul style="list-style-type: none"> • 13 more Primary CPGs • 13 more Secondary • 3 more Tertiary 			These 45 conditions & 81 CPG (at 3 levels) account for approx. 80-90% of all care delivered and resources used at pilot sites		
2.	% of patients treated in compliance with CPGs at pilot sites (n=10 treatment per CPG per site; observed by MoH CPG expert for 5 target conditions)		Primary	Secondary		Primary	Secondary	Baseline higher CPG non-compliance at secondary level is caused by later EHTP-facilitated MoH approval of these CPGs. Data show care improvement in pilot sites in 2003		
		Issyk-Ata	70%	10%	I-A	68%	91%			
		Ak-Tala	58%	27%	A-T	95%	93%			
		At-Bashy	50%	39%	A-B	95%	58%			
3.	Primary level (treated for 5 key conditions)		I-A	A-T	A-B		I-A	A-T	A-B

Table 46-7 Quality indicators with potential for improvement through EHTP in Kyrgyzstan

No.	Indicator	How EHTP Can Help	Baseline Measurement Recommended	Re-measurement Period Recommended
1.	Population health (gains) <ul style="list-style-type: none"> ● Desired process outcomes ● Desired care outcomes ● Overall level raised ● Distributed appropriately ● Health system-related outcomes' accountability, e.g., timing of care, sustainability of delivery system performance ● Provide performance and incentives re outcomes (see 16 below) ● Health expectancies & gaps 	<ul style="list-style-type: none"> ● Quality can be improved either by better use of existing resources or through contribution of added resources. EHTP models an integrated solution here based on best science that can be used in light of existing constraints. ● EHTP can assist in measuring outcomes, competence, appropriateness, safety, timeliness, preventive care, access, availability, and continuity of care. 	Selected process & care outcomes are currently being measured. Others could be chosen based on other key epidemiological conditions, with baseline in 2003.	2003 and beyond
2.	Responsiveness of the health system to legitimate expectations of the population (excludes health improving dimensions noted in 10.) <ul style="list-style-type: none"> ● Increase average level ● Reduce inequalities in responsiveness ● Respect for the person: dignity, autonomy, need for confidentiality and information; patient's demand & rights ● Respect for customer (client) orientation: prompt attention, provision of basic amenities, access to social support networks, and choice 	<ul style="list-style-type: none"> ● Satisfaction surveys could be added to measurements by the EHTP central Coordinating Office Team at pilot sites and other sites as country-wide implementation proceeds to measure and begin to improve existing responsiveness. This information could be brought back to monthly EHTP National Commission meetings for discussion and referral to appropriate branches of MoH for follow-up action. ● Measures could include patient choice, patient experience, acceptability, respect & caring, availability of information, and timeliness. 	2003	2004
3.	Fairness in financing (financial risk protection for households – should not impoverish patients; poorer patients should pay lower proportion of disposable income) Note evidence that prepaid financing that are publicly financed are more successful in containing costs & making health gains. Balance risk by capitation with providers and fair co-payment by patients. Stimulate competition between providers by giving feedback on provider performance to patients; must be in context of strong government regulation & publicly financed system.	<ul style="list-style-type: none"> ● Extensive MoH efforts ongoing regarding health finance reform to support fairness. EHTP cost indicators could continue to inform this process at the local, district and central levels. ● Measures could include affordability, access, availability, and continuity. ● Could also include Provider Performance, see 16 below. 	2002	2003 and beyond
4.	Health system inputs (amount and quality of resources, typically health expenditures per capita) <ul style="list-style-type: none"> ● Recurrent costs of service provision ● Physical availability of inputs ● Skill mix of health care personnel ● Utilization of medical equipment and facilities 	<ul style="list-style-type: none"> ● These are currently standard EHTP measures that could be used in a variety of ways by MoH. 	2002	2003 and beyond
5.	Health system organizational structure and processes <ul style="list-style-type: none"> ● Level and type of autonomy and integration ● Incentive structures 	<ul style="list-style-type: none"> ● Understanding how health resources are individually managed and then integrating these activities through EHTP is a key way it assists the MoH. ● Using EHTP to develop data to assist in establishing provider and local, district and central health system incentives is a logical next step. 	2003	2004
6.	Coverage with Effective Interventions (the probability of receiving a necessary health intervention conditional on the presence of a certain health problem or need) <ul style="list-style-type: none"> ● Access (availability, accessibility, affordability, acceptability) ● Utilization (access, personal health behavior) ● Effectiveness (efficacy, inputs, QA mechanisms, patient compliance, & external factors) ● At individual level, also measure inequality of effective coverage 	Criteria for how interventions are identified for measurement of effective coverage: <ul style="list-style-type: none"> ● Able to produce health gain in relatively short time period ● Size of health problem at global and country level ● Evidence on effectiveness of interventions, and inherent credibility ● Aligns with national health priorities, needs, policies ● Balance between different modalities of health care ● Cost-benefit ratio of obtaining information at country level ● Able to link global processes with country priorities 	2003	2004
7.	Provider Performance <ul style="list-style-type: none"> ● Individual provider quality performance & competency ● Individual provider safety performance ● Provider motivation & incentives based on performance 	<ul style="list-style-type: none"> ● EHTP provides the tools to assess and improve these measures, in partnership with MoH. 	2003	2004
8.	Improving Health System Efficiency Varies according to the choices a country makes about the mix of interventions purchased with available health expenditures, includes both technical and allocative efficiency.	<ul style="list-style-type: none"> ● WHO recently completed this measure this for all of its 191 member countries. ● WHO studies indicated that more outcome goals can be met without always increasing health expenditures; EHTP provides the means for this assessment. 	2003	2004
9.	National Quality Assurance (QA) / Quality Improvement (QI) Programs through Accreditation EHTP processes for improving health system resource planning and management provide the framework to assist in QA/QI accreditation activities.	<ul style="list-style-type: none"> ● EHTP's national implementation is a natural link for establishing accreditation programs for inpatient and ambulatory facilities. The United States models of JCAHO accreditation for inpatient facilities and NCQA for ambulatory facilities links well with EHTP's methodology and tools. 	2003	2004
10.	Patient Safety Health care interventions are intended to benefit patients but they also cause harm. The complex combination of processes, technologies & human interactions in a health delivery system can bring benefits but also cause adverse events.	<ul style="list-style-type: none"> ● EHTP directly addresses many of these issues, could assist national efforts to emphasize patient safety as a concern in health system performance and quality management, and help establish the evidence base of adverse events. 		

Table 46-7 Quality indicators with potential for improvement through EHTP in Kyrgyzstan—cont'd

No. Indicator	How EHTP Can Help	Baseline Measurement Recommended	Re-measurement Period Recommended
<p>Developing countries often need particular attention for adverse events due to poor state of infrastructure and equipment, unreliable supply and quality of drugs, shortcomings in waste management and infection control, poor performance of personnel because of low motivation or insufficient technical skills, and severe under-funding of essential operating costs.</p>	<p>● In partnership with a health economist who understands all of the constraints involved, the information generated from and able to be modeled by the EHTP tool can potentially be a powerful tool in various forms of CEA.</p>	2003	2004
<p>11. Cost –Effectiveness Analysis CEA CEA of a wide range of interventions can be undertaken to inform a specific decision-maker. This person faces a known budget, and a series of other constraints. A decision-maker may be able to allocate an entire budget or only a budget increase; he may be a donor, a MoH, a district medical officer, or a hospital director. Choices available are typically limited by some combination of health resources or the current mix of interventions.</p>

Section IV

Management

Alfred M. Dolan

Samuel Lunenfeld Associate Professor in Clinical Engineering, Associate Director, Institute of Biomaterials and Biomedical Engineering, University of Toronto
Toronto, Ontario, Canada

The field that is now referred to as “clinical engineering” needs to be considered in the context of the development of biomedical engineering and in turn, engineering.

A number of years ago the following definition of engineering served to illustrate that the profession has long recognized its responsibility in applying the application of scientific techniques, theories, and technology for the solution of societal needs.

“In the past engineering was defined as the facility to direct the sources of power in nature for man’s use and convenience (Dolan et al, 1973).”

That definition presents issues which all engineers, and clinical engineering professionals in particular must address. Those issues are of course the need to maintain an appropriate level of scientific knowledge and technological skills and a commitment to define and meet the real societal needs in health care. These issues are addressed as the different aspects of clinical engineering practice are discussed in the chapters of this book.

Biomedical engineering origins can be traced to ancient times through the work of such people as Alcmaeon, Plato, and Galen who investigated, observed, and systematized the world they studied around them including the human body. Galen’s work on hemodynamics persisted for more than 1200 years to the time of Maimonides. Leonardo da Vinci, who was arguably the greatest engineer in history, also applied physical principles and experimental analysis to the study of physiology and medicine. Helmholtz built on his own early interests in physics and mathematics to undertake a career in medicine in 1838. He made prodigious contributions to the understanding of physiology and invented the ophthalmoscope he needed to investigate the physiology and psychology of hearing.

Investigators, scientists, and engineers like Helmholtz understood that the same laws apply to studies of physics, engineering, or biology—the unity of the sciences and the essence of biomedical engineering. That understanding represents the great challenge and potential for the applied side of biomedical engineering, which has come to be called clinical engineering, where all aspects of science, engineering and technology come to play directly in the health care field.

Clinical engineering has developed in health care facilities around the world over the last four decades of the 20th century. There was broadly held recognition of the technological explosion that had affected society in general and health care in particular, and a series of workshops held in 1972 provided a forum for the discussion of the need for an engineering approach to effect some control on this technology (Hopps, 1972; Craig, 1972). That and subsequent work serves to illustrate that there was recognition of the problems that existed in health care in that time period but further that there was recognition of the potential for biomedical engineering to solve them. It was, however, not only engineers who realized how broad that problem solving role could become. That broader understanding came from visionaries like Robert Rushmer, a cardiovascular research scientist, and Cesar Caceres, a clinical cardiologist, whose recognition of what the range of engineering involvement in health care could be defines, in essence, the role of clinical engineering.

Cesar Caceres offered perhaps the most insightful description of clinical engineering: “An engineer who is trained for and works in a health service facility where he or she is responsible for the direct and immediate application of engineering expertise to health and medical care (Caceres, 1980).”

While this definition unnecessarily constrains the practice of clinical engineering to that being within the precincts of the hospital, it still accurately outlines the role of clinical engineering and assumes both appropriate engineering expertise, and direct benefit to patient care or health care. Some three decades later the American College of Clinical Engineering emphasizes both patient care and management by defining a clinical engineer as “a professional who supports and advances patient care by applying engineering and management skills to health care technology (ACCE, 2001).”

Health care and the science and technology supporting health care will continue to develop. This accelerating trend in scientific developments in health care will in turn, drive the development in clinical engineering. In keeping with our understanding of clinical engineering as supporting and advancing patient care through application of engi-

neering management and technology, it is important to recognise that the field of clinical engineering will need to continue to develop as health care develops. This will include developments both in sophistication, such as physiological functional imaging or highly integrated information systems, and in scope, such as in wellness care or in distributed clinical care. Active development in clinical engineering will be required if the field is to continue to thrive and it is toward that end that this Handbook endeavours to encourage the profession.

This section addresses management issues from the perspective of engineers who have applied management principles in their professional careers in the health care environment. Seaman (Industrial/Management Engineering in Health care) with case studies makes a convincing case for utilizing the special skills and insight of clinical engineers to improve the utilization of and maximize the investment in health care technology. Seaman, working with the Editor-in-Chief of this Handbook in a tertiary-care hospital, demonstrated that sound industrial/management techniques applied in the clinical setting yielded enhanced medical device utilization. Wang (Financial Management of Clinical Engineering Services) provides comprehensive description of the financial concepts the clinical engineering must embrace to manage effectively with available resources. He gives concrete examples of best financial management principles and offers templates for putting the principles into practice. Fennigkoh (Cost-effectiveness and Productivity), in providing the tools with which the clinical engineer can measure the output of the clinical engineering department, shows the CE how to maximize on available human resources to yield optimal medical device technology management. In order to improve on a department’s performance, one must understand its objectives, appreciate its resources, and measure its accomplishments. Autio (Clinical Engineering Program Indicators) recommends ways by which the clinical engineer can use indicators of performance to enhance overall departmental operations.

The human aspect of the clinical engineer’s role in management is emphasized in Personnel Management (Wear), Skills Identification (Cram), and Management Styles and Human Resource Development (Epstein and Harding). The precious resource of the individual must be appreciated, nurtured, developed, guided and encouraged to function at the highest levels. Wear gives an overview of the responsibilities of the clinical engineering director in recruiting and retaining personnel. Cram affirms that identifying the skills of each employee is at the foundation of effective work performance. That there is not one simple formula for managing and for developing human resources is emphasized by Epstein and Harding as they trace the development of management techniques over time and space. Judd completes the picture with an insightful chapter on quality. He draws upon his broad and extensive experience in putting into practice methods for achieving the best results. He shows how to assess present levels of performance and recommends techniques and tools to achieve higher levels of quality.

Industrial/ Management Engineering in Health Care

George Seaman

President, Seaman Associates
Northport, NY

If it moves, it's Mechanical;
If it doesn't, it's Civil;
If it smells, it's Chemical;
If it is invisible, it's Electrical;
And if you can't even imagine it, it's INDUSTRIAL!

The IE page at the University of Nebraska.

Attributed to Professor Schmuel S. Oren, UC -Berkeley.

Industrial/management engineering is probably the broadest of all the engineering disciplines. Industrial/Management engineers (I/MEs) integrate human, information, material, monetary, and technological resources to produce goods and services optimally. Major areas of specialization applied in the health care sector include:

- Engineering economics and decision analysis
- Human factors engineering
- Process/service delivery systems
- Operations research/resource optimization/decision science
- Logistics, information, and materials management
- Statistical analysis/quality management
- Stochastic systems/simulation/modeling

Typically I/MEs are people-oriented problem solvers whose assignments address management decision making. They tend to be diverse, often requiring interaction with health care administrators and specialists such as those who have particular expertise in biomedical technologies with the underlying guideline of providing optimal care to patients.

According to the ACCE definition (Bauld, 1991), a clinical engineer (CE) is a professional who supports and advances patient care by applying engineering and management skills to health care technology. As health care has become increasingly dependent on more sophisticated technology and associated complex biomedical equipment, the clinical engineer's role has risen to the level of the technology officer in supporting health care organizations with technology planning, implementation, and ensuring a safe and efficient utilization during the life span of the technology.

Both skill sets complement each other in the areas of general engineering knowledge, and both require a unique set of management skills and knowledge specific to their areas of specialization. Aligned toward a specific goal, a synergistic model can emerge that can result in a rationally planned and well-executed implementation of technological change. This chapter facilitates the understanding of what the I/ME does, by demonstrating problem solving strategies and the way I/MEs can work effectively with the CE in working with the new and old frontiers of technology in health care organizations.

Definition of an Industrial/Management Engineer

"Efficiency is doing things right; effectiveness is doing the right things."—Peter F. Drucker

I/MEs design the optimal combination of human and natural resources to make systems perform at their best. The integration of people, materials, capital, equipment, and energy into production systems is the I/ME's main concern. An I/ME may be involved in scheduling staff and systems resources, designing health care delivery systems, or building information systems to support organizational development and decision making.

The U.S. Bureau of Labor Statistics has described a typical I/ME's function as follows: Industrial engineers determine the most effective ways for an organization to use the basic factors of production—people, machines, materials, information, and energy to make or process a product. They are the bridge between management and operations. They are more concerned with increasing productivity through the management of people, methods of business organization, and technology than are engineers in other specialties, who generally work more with products or processes.

The I/ME's Role in Decision Making

"The purpose of a model is not to fit the data but to sharpen the questions"—Samuel Karlin, 11th R A Fisher Memorial Lecture, Royal Society 20, April 1983

Decision science is an essential part of an I/ME's training in the development of modeling skills. A model is an abstraction of a real-world process, such as transport-delivery system, customer service, or behavior of health care markets. Sound analysis of a model's output can help to improve an organization, service, or program's performance. In order for such models to be beneficial, their results must be clearly communicated to the company. In order to identify the problem and to utilize the information that the models generate, the ability to ask the right questions and good acumen in listening and communication skills are necessary.

The Bureau of Labor Statistics has also noted that to solve organizational, production, and related problems most efficiently, industrial engineers carefully study the product (or process) and its requirements, design logistics and information systems, and use mathematical analysis methods (such as operations research) to meet those requirements. They develop management control systems to aid in financial planning and cost analysis, design production (or process) planning and control systems to coordinate activities and to control product (or service) quality, and design or improve systems for the physical distribution of materials and services. Industrial engineers conduct surveys to find facility locations with the best combination of resources, transportation, accessibility, and costs. They also develop wage-and-salary administration systems and job-evaluation programs. Many industrial engineers move into management positions because the work is closely related to the art of management science.

Decision-Making in Health Care

"Success is relative: It's what we can make of the mess we have made of things."

— T. S. Eliot

The health care industry is the largest single industry in the United States, comprising over 700,000 physicians and 5000 hospitals. Total expenditures exceed \$1.3 trillion dollars, and according to some experts, the figure is expected to double by the year 2007 (HCFA, 1997). This increase in costs in delivery of health care services has caused the federal government, employers, and consumer groups to pressure the health care industry into seeking more cost-efficient methods for servicing a growing number of health care consumers, e.g., Baby Boomers. Concomitant with rising costs, health care organizations are under pressure to respond to increased regulations, e.g., the Health Insurance Portability and Accountability Act (HIPAA), (see Chapter 104), increasingly complex and cumbersome managed-care constructs, e.g., precertifications, bundling of services in response to optimize HMO reimbursement structuring, and to contend with aging technology and infrastructure.

On the horizon is the new world of technology that is growing at a geometric rate and promising fantastic medical strides in genetics and molecular biology, pharmacology, medicine and surgery, diagnostic tools, physiological monitoring, and robotics. These and the informatics that cross-section all of these technologies promise momentous advantage and value. These new developments often put the chief executive officer (CEO) in an investment quandary between managing costs and buying something that will improve quality and reduce (or contain) future costs (improving value). If the investment is large, as almost all health care investments are, there may be federal, state, and local regulatory impediments that may take so long as for the investment to lose its utility as a "competitive" instrument or, worse, render the technology nearly obsolete. This is particularly critical to a smaller hospital that might not have the funding capability of a large medical center or network that can absorb the risk; however, it must invest to survive.

There are occasions when the CEO must make an investment to attract or retain a prominent physician, respond to physician or consumer-community pressure, or, more imperatively, respond to an urgent or emergent situation to avoid a disastrous outcome. Regardless of the investment quagmire, hospitals must invest in technology to thrive and to continue doing the "right thing." But in doing so, how does the CEO know in the decision to invest is the right way? Finance can work out the break-even, the physician or nurse can tell him or her how great it performed at XYZ hospital or conference, or a board member can provide a nudge. But the CEO is accountable and, therefore, must rely on other factors that effect his or her decision and the future of the organization.

Planning

"Whatever failures I have known, whatever errors I have committed, whatever follies I have witnessed in private and public life have been the consequence of action without thought."—Bernard M. Baruch

Technology Acquisition

“When the only tool you have is a hammer, then every problem begins to look like a nail.”—Abraham Maslow

How does the acquisition of technology start? It should start at the strategic planning level. (See Chapters 30 and 32.) Because technology is extremely dynamic, planning at the micro level should be near the endpoint, and not the beginning! Often, the capital budgeting process serves as a surrogate for the strategic planning process. It requires uninformed staff members to provide a guesstimate of their needs and desires, usually in short order, and often without a knowledge cross-connect to other services. This is disastrous in the sense that using a capital budget as the strategic plan will result in suboptimal utilization of technology, such as creating an implementation-connectivity nightmare; exorbitant service contract and inventory costs; or buying soon-to-be-obsolete technology and leaving the disconnected I/ME and CE to contend with a plethora of patchwork and other unnecessary operational implementation and management challenges that otherwise could have been avoided.

Engineering Economics and Decision Analysis

A Tale of Two CT’s A major driving force behind many management decisions and fundamental to Business 101 is turning a profit. In non-profit health care facilities it is a contribution to margin. The I/ME often plays a major role in providing the analytic work to support decision making through a variety of techniques. For example, consider a radiology service that has purchased a new CT scanner in addition to their current machine to meet increasing demand. Each unit takes a different length of time to scan the patient. Because CT_A is new, it averages 16 minutes per scan, while the used scanner, CT_B, averages 24 minutes per scan. The total time to process a patient averages 12 minutes per patient, net of either scanner’s processing time. Previous cost analysis determined that 24 patients per day had to be processed for the service to break even.

To determine a solution, we must look at the processing rates. The rate for CT_A is 2.1 patients per hour (60 min/hr/ 16+12 minutes per patient) and 1.7 patients/hr for CT_B. If the facility operates for seven hours, a total of 26.6 patients/day can be processed, assuming a steady state operation, so the service easily breaks even. However, delays such as patients arriving late, staff breaks, absenteeism, lost paperwork, and machine delays all contribute toward undermining that ideal state. If five minutes per patient added for delay variances or the unit incurred X minutes of down time were factored in the process daily volume would be reduced to 23 patients per day, thus sustaining a perpetual loss. The reality is that there are stochastic processes at work that cause delays that are variable in duration and not evenly distributed on a per patient basis. This can result in as much as a 20% reduction in utilization, or 18–20 patients per day in this case.

The I/ME in applying a particular approach can conduct a time study analysis and construct a flow process chart to identify ways to reduce the patient processing time by eliminating or combining steps, or removing certain steps in the “critical path” of the process to reduce the direct processing time. Other tools might include a simulation of the process where a dynamic flow of sequenced of events emulating the work process can be constructed, and specific events or subprocesses varied to determine service-time sensitivity while incorporating those stochastic processes such as patient arrivals and resource down time.

If performed within a rational planning process, this analysis could be performed prior to purchasing equipment with predetermined time standards, logistics, and monitoring in place. A note of interest: The hospital decided to utilize all inclusive service contracts that totaled \$92,000 per year. If the hospital had utilized the in-house clinical engineering

department, not only would they have saved money, but there would have been added value in utilizing during the CE’s non-CT dedicated time as well.

Project Management

“Everything is okay in the end. If it’s not okay, then it’s not the end.”—Unidentified

Managing Large, Complex Projects

Gantt Chart

A Gantt chart is a horizontal bar chart developed as a production-control tool in 1917 by Henry L. Gantt, who was an American engineer and social scientist. Frequently used in project management, the Gantt chart provides a graphical illustration of a schedule that helps to plan, coordinate, and track specific tasks in a project (Figure 47-1). Gantt charts can be simple versions created on graph paper, or more complex, automated versions created using project management applications such as Microsoft Project or Excel. (See, e.g., <http://goanna.cs.rmit.edu.au/~geofft/280/cgi/sample/timing/section1.htm>)

PERT Chart

The limitation of a Gantt chart is that it does not show interdependency. A PERT chart, (“Program Evaluation Review Technique”) was developed by the U.S. Navy in the 1950s to manage the Polaris submarine missile program to overcome that limitation. These are often combined with critical path method (CPM), which was developed in the private sector around the same time. CPM identifies the path sequence that is most critical to completing the project.

A PERT chart presents a graphic illustration of a project as a network diagram consisting of numbered nodes (either circles or rectangles) that represent events or milestones in the project, linked by labeled vectors that represent tasks in the project. The direction of the arrows on the lines indicates the sequence of tasks. In the PERT chart shown in Figure 47-2, for example, the tasks among nodes 1, 2, 4, 8, and 10 must be completed in sequence. These are called dependent or serial tasks. The tasks between nodes 1 and 2, and between nodes 1 and 3 are not dependent on the completion of one to start the other, and they can be undertaken simultaneously. These tasks are called “parallel” or “concurrent” tasks. Tasks that must be completed in sequence, but that do not require resources or completion time, are considered to have event dependency. Represented by dotted lines with arrows, these are called “dummy activities.” For example, the dashed arrow linking nodes 6 and 9 indicates that the system files must be converted before the user test can take place, but that the resources and time required to prepare for the user test (e.g., user training and writing the user manual) are on another path. Numbers on the opposite sides of the vectors indicate the time allotted for the task

These techniques are useful in organizing, managing, assigning responsibility, and updating status on large, complex projects. Typically, the I/ME will create a list of tasks working with specialists such as architects, other engineers, and programmers and will develop and organize a more detailed list of activities, sequence the necessary events, and determine the interdependencies between activities and events. This particular specialty of I/ME falls under project management, which is an entire field in itself. There are certified project managers (PMs), special tools used for developing schedules, and international societies devoted to this important field. (For more information on project management, see <http://www.allpm.com/static.html>.)

Reusable vs. Disposable Blood Pressure Transducers: A Case Study

“An approximate answer to the right question is worth a good deal more than the exact answer to an approximate problem.”—John Tukey

The following is one example of how the areas of specialization of an I/ME and CE can be combined in analyzing cost/benefit use of alternative medical devices in a hospital: The cost of reusable transducers had been on the increase over the previous year. At the behest of a sales representative, a hospital administrator wanted to evaluate the use of disposable transducers. The I/ME reviewed the problem with the CE and began to structure an approach. Looking at the numbers in a “make/buy” analysis, the reusable transducer cost \$275 while a disposable one cost \$2.38. Total inventory was 149 transducers, with 12 in storage. Random sampling indicated that, on average, 82% of the transducers were in use on a daily basis. The average repair rate was 26 per month at a cost of \$63 in parts, labor (CE cost based on time-study analysis), and overhead, and a replacement rate of 37 per month.

On the surface, this is a simple problem. Extending the replacement cost on an annual basis comes out to \$141,756/year: (37 replacements/mo. \times \$275/txd 12/mo/yr) + (26 repairs/mo \times \$63/Repair \times 12 mo.). Using disposable units would cost \$114,686/yr: (161 transducers \times 82% utilization \times \$2.38/transducer). Using disposable units would yield a savings of \$27,000/year. Clearly, the choice would be to use disposables.

The clinical engineering director, however, had the intuition and foresight to have previously enacted development of a comprehensive medical equipment management system (MEMS) (Dyro, 1984, 1993). Given the wealth of data available through the system, the I/ME decided to look more closely at Mean Time Between Failure (MTBF) rates by user group.

The results were startling. The I/ME identified two units that had the shortest MTBF and consequently the highest replacement and repair rate. The culprits were an intensive care unit (ICU) and the operating room (OR). Upon interviewing the staff in these locations, the I/ME determined that they often mishandled these transducers—sometimes just tossing them on a table, sometimes dropping them on the floor. The answer became crystal clear: Training, sensitizing, storage accessibility, and monitoring of staff who handle the transducers. By reducing the incidence of breakdown by 20%, the cost was shifted in favor of reusable transducers. Of course, this course of action was transmitted to all areas, thus resulting in a sharp decrease in repairs and significantly increasing the MTBF and financial savings.

Resource Optimization/Operations Research

“Mathematicians do not study objects, but relations between objects. Thus, they are free to replace some objects by others so long as the relations remain unchanged. Content to them is irrelevant: They are interested in form only.”—Jules Henri Poincaré (1854–1912)

The field of operations research (OR) took root in the years just prior to World War II. In 1938, experiments began to explore ways in which information provided by radar could

be used to direct aircraft. A multidisciplinary team of scientists working on this radar/fighter plane project studied the actual operating conditions of these new devices and designed experiments in the field of operations, and the new term “operations research” was born. The team’s goal was to derive an understanding of the operations of the complete system of equipment, people, and environmental conditions (e.g., weather and time of day), and then to improve upon it. Their approach was later paralleled in the U.S. with the first team working on antisubmarine tactics. The U.S. group developed a series of mathematical models, “entitled search theory,” that were used to develop optimal patterns of air search. Today, each branch of the U.S. military has its own operations-research group that includes both military and civilian personnel. OR moved into the industrial domain in the early 1950s and paralleled the growth of computers as a business planning and management tool. As the field evolved, the core moved away from interdisciplinary teams to a focus on the development of mathematical models that can be used to model, improve, and even optimize real-world systems. They include deterministic models such as mathematical programming, routing or network flows, as well as probabilistic models such as queuing, simulation and decision trees. The following are simple examples in linear programming:

Production Planning

“How can it be that mathematics, being after all a product of human thought independent of experience, is so admirably adapted to the objects of reality?”—Albert Einstein (1879–1955)

Example 1

A gynecologic service performs two diagnostic tests (X and Y) using two machines (A and B). Each patient who has an X diagnostic test procedure requires 50 minutes processing time on machine A and 30 minutes processing time on machine B. Each patient who requires a Y diagnostic test procedure requires 24 minutes processing time on machine A and 33 minutes processing time on machine B.

At the start of the current week, there are 30 patients for of X and 90 patients for Y on the schedule. Available processing time on machine A is forecast to be 40 hours and on machine B it is forecast to be 35 hours (an additional 1hr/day for setup and QC).

The average demand for X in the current week is forecast to be 75 patients, and for Y it is forecast to be 95 patients. Service policy is to maximize the combined sum of the patients of X and of Y scheduled during the week. The following approaches can be taken:

- Formulate as a linear program the problem of determining how many of each group of patients to process in the current week.
- Solve this linear program graphically.

Let

- x be the number of diagnostic test procedures of X patients in the current week
- y be the number of diagnostic test procedures of Y patients in the current week

Figure 47-3 Graphical solution to determine the maximum the number of patients processed each week.

Then the constraints are:

- $50x + 24y \leq 40(60)$ machine A time
- $30x + 33y \leq 35(60)$ machine B time
- $x \geq 75 - 30$
- i.e., $x \geq 45$ so production of X \geq demand (75)–initial schedule (30), which ensures that we meet demand
- $y \geq 95 - 90$
- i.e., $y \geq 5$ so production of Y \geq demand (95)–initial schedule (90), which ensures we meet demand

The objective: Maximize $(x+30-75) + (y+90-95) = (x+y-50)$, i.e., to maximize the number of patients processed by the end of the week, Figure 47-3 shows that the maximum occurs at the intersection of $x = 45$ and $50x + 24y = 2400$.

Solving simultaneously, rather than by reading values off the graph, we have that $x = 45$ and $y = 6.25$ with the value of the objective function being 1.25.

Example 2

Obviously, in the real world there are many problems that exceed two-dimensional states. Variables with greater than 10 variants are not unusual. Consider the following example:

A CE department provides four variants of a service, i.e., in-house, contract-out, a hybrid of the two, OEM service. In the final part of the process, there are diagnostic, repair, and preventive maintenance. For each variant, the time required for these operations is shown in Table 47-1 (in minutes), as is the marginal cost contribution (MCC) per unit repaired (i.e., profit).

Given the current state of the professional workforce, the department estimates that each year they have 100,000 minutes of diagnostic time, 50,000 minutes of repair time, and 60,000 minutes of checkout time available. What apportionment of each variant should the department service per year, and what would be the associated MCC?

Suppose now that the department is free to decide how much time to devote to each of the three operations (diagnosis, repair, and PM) within the total allowable time of 210,000 (= 100,000 + 50,000 + 60,000) minutes. How many of each variant should the department make per year, and what would be the associated profit?

Production-planning solution:

Variables

- Let: x_i be the number of units of variant i ($i=1,2,3,4$) made per year
- T_{diag} be the number of minutes used in diagnosis per year
- T_{rep} be the number of minutes used in repair per year
- T_{chk} be the number of minutes used in PM per year

where $x_i \geq 0$ $i=1,2,3,4$ and $T_{diag}, T_{rep}, T_{pm} \geq 0$

Constraints

(a) operation time definition

$T_{diag} = 20x_1 + 40x_2 + 30x_3 + 70x_4$ (diagnosis)
 $T_{rep} = 30x_1 + 20x_2 + 30x_3 + 40x_4$ (repair)
 $T_{pm} = 20x_1 + 30x_2 + 20x_3 + 50x_4$ (pm)

(b) operation time limits

The operation time limits depend upon the situation being considered. In the first situation, where the maximum time that can be spent on each operation is specified, we simply have:

$T_{diag} \leq 100,000$ (diagnosis)
 $T_{rep} \leq 50,000$ (repair)
 $T_{pm} \leq 60,000$ (pm)

Table 47-1 Times for diagnosis, repair, PM, and profit (i.e., marginal cost contribution [MCC]) for each of four variants

	Diagnosis (min)	Repair (min)	PM (min)	MCC (\$)
Variant 1	20	30	20	1.50
Variant 2	40	20	30	2.50
Variant 3	30	30	20	3.00
Variant 4	70	40	50	4.50

In the second situation, where the only limitation is on the total time spent on all operations, we simply have:

$T_{diag} + T_{rep} + T_{pm} \leq 210000$ (total time)

Objective: Maximize MCC—thus, the objective function is:

maximize $1.50x_1 + 2.50x_2 + 3.00x_3 + 4.50x_4$

There are a variety of software packages and mathematical modeling techniques that can be used to solve these and other problems. This is but the surface of the types of problem-solving techniques used by I/MEs and OR scientists. One Windows®-based version of these packages is called WinQSB®, and there are several other packages that employ spreadsheet methodologies for solving complex OR problems.

Decision Trees

“The roads we take are more important than the goals we announce. Decisions determine destiny.” – Frederick Speakman

In many problems, chance (or probability) plays an important role. “Decision analysis” is the general name that is given to techniques for analyzing problems that contain risk/uncertainty/probabilities. Decision trees are one specific decision-analysis technique.

Example 1:

A company faces a decision with respect to a medical instrument, Model M997, developed by one of its research laboratories. It must decide whether to test market M997 or to drop it completely. The company estimates that test marketing will cost \$100K. Past experience indicates that only 30% of products are successful in test markets. If M997 is successful at the test-market stage, then the company will face a further decision relating to the size of plant to set up to produce M997. A small plant will cost \$150K to build and to produce 2000 units a year, while a large plant will cost \$250K to build and to produce 4000 units a year. The marketing department has estimated that there is a 40% chance that a competitor will respond with a similar product and that the price per unit sold will be as follows (assuming that all production is sold):

	Large plant	Small plant
If competition respond	\$20	\$35
If competition do not respond	\$50	\$65

Assuming that the life of the market for M997 is estimated to be seven years and that the yearly plant-running costs are \$50,000 (for both sizes of plant), should the company proceed with test marketing M997?

To view this problem, consider the decision tree shown in Figure 47-4.

- Decision nodes represent points at which the company must make a choice of one alternative from a number of possible alternatives (e.g., at the first decision node, the company must choose one of the two alternatives: “drop M997” or “test market M997.”)
- Chance nodes represent points at which chance, or probability, plays a dominant role and that reflect alternatives over which the company has (effectively) no control.
- Terminal nodes represent the ends of paths from left to right, through the decision tree.

Solution—Step 1 For each path through the decision tree, from the initial node to a terminal node of a branch, one works out the profit (in dollars) involved in that path. Essentially, in this step, one works from the left-hand side of the diagram to the right-hand side.

- Path to terminal node 2—we drop M997.
 Total revenue = 0
 Total cost = 0
 Total profit = 0

Money that already has been spent on developing M997 is a “sunk cost” (i.e., a cost that cannot be altered, no matter what our future decisions are) and has no part to play in deciding future decisions.

- Path to terminal node 4—we test market M997 (cost \$100,000) but then find that it is not successful, so we drop it.

Total revenue = 0
 Total cost = 100
 Total profit = -100 (all figures in \$K)

- Path to terminal node 7—we test market M997 (cost \$100K), find it is successful, build a small plant (cost \$150K), and find that we are without competition (revenue for seven years at 2000 units per year at \$65 per unit = \$910K).

- This continues for each path to terminal node.

Solution—Step 2 Consider chance node 6 with branches to terminal nodes 7 and 8 emanating from it. The branch to terminal node 7 occurs with probability 0.6 and total profit

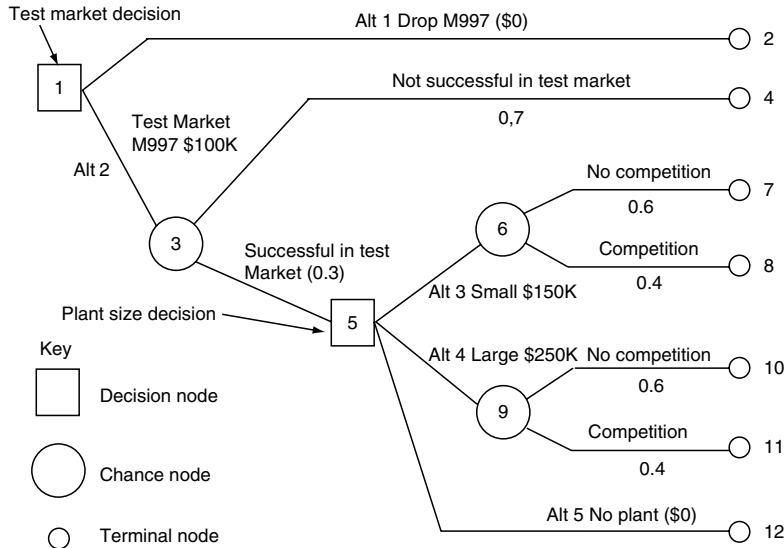

Figure 47-4 Decision tree to determine whether a company should test market a medical device.

of 310K, while the branch to terminal node 8 occurs with probability 0.4 and total profit of -110K. Hence, the “expected monetary value” (EMV) of this chance node is given by:

$$0.6 \times (310) + 0.4 \times (-110) = 142 \text{ (\$K)}$$

Essentially this figure represents the expected (or average) profit from this chance node (60% of the time we get \$310K and 40% of the time we arrive at -110K so on average we get $(0.6 \times (310) + 0.4 \times (-110)) = 142 \text{ (\$K)}$).

The EMV for any chance node is defined by “sum over all branches, the probability of the branch multiplied by the monetary (\$) value of the branch.” Hence, the EMV for chance node 9 with branches to terminal nodes 10 and 11 emanating from it is given by:

$$0.6 \times (700) + 0.4 \times (-140) = 364 \text{ (\$K)}$$

node 10 node 11

A decision node relating to the size of plant to build now can be developed as in Figure 47-5, where the chance nodes have been replaced by their corresponding EMVs. The plant-decision node now presents three alternatives:

- Alternative 3: Build small plant EMV = 142K
- Alternative 4: Build large plant EMV = 364K
- Alternative 5: Build no plant EMV = -100K

It is clear that, in dollar terms, alternative number 4 is the most attractive alternative, so we can discard the other two, giving the revised decision tree shown in Figure 47-6.

Repeating the process carried out above:

The EMV for chance node 3 representing whether or not M997 is successful in test market is given by

$$0.3 \times (364) + 0.7 \times (-100) = 39.2 \text{ (\$K) plant decision node node 4}$$

Hence, at the decision node representing whether or not to test market M997, we have the two alternatives:

- Alternative 1: Drop M997 EMV = 0
- Alternative 2: Test market M997 EMV = 39.2K

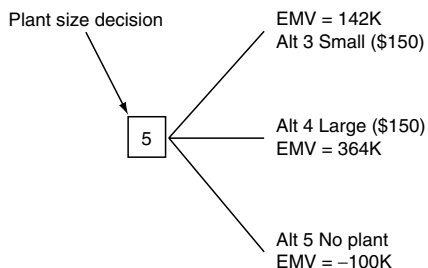

Figure 47-5 Decision tree to determine the size of a manufacturing plant to build.

It is clear that, in dollar terms, alternative number 2 is preferable, so we should test market M997 given that this decision has an expected monetary value (EMV) of \$39.2K. If M997 is successful in test market then we anticipate, at this stage, building a large plant (reference the alternative chosen at the decision node relating to the size of plant to build). However, in real-life situations another review should take place after test marketing has been completed.

Example 2:

A company is trying to decide whether or not to bid for a certain contract. It estimates that merely preparing the bid would cost \$10,000. If the company were to bid, then it is estimated that there is a 50% chance that the bid would be put on the “short list” of competitors, but otherwise their bid will be rejected.

Once “short listed,” the company will have to supply further detailed information (entailing costs estimated at \$5,000). After this stage, this bid will be accepted or rejected.

The company estimates that the labor and material costs associated with the contract are \$127,000. It is considering three possible bid prices: \$155,000, \$170,000, and \$190,000. It estimates that the probabilities of these bids being accepted (once they have been short listed) are 0.90, 0.75, and 0.35, respectively.

What should the company do, and what is the expected monetary value of your suggested course of action?

Solution Refer to the decision tree for the problem shown in Figure 47-7.

Below, step 1 of the decision tree solution procedure is carried out, which (for this example) involves calculating the total profit for each of the paths from the initial node to the terminal node (all figures in \$).

Step 1

path to terminal node 7—the company would do nothing Total profit = 0

- path to terminal node 8—the company would prepare the bid but would fail to make the short list

Total cost = 10 Total profit = -10

- path to terminal node 9—the company would prepare the bid and would make the short-list, and their bid of \$155K would be accepted

Total cost = 10 + 5 + 127 Total revenue = 155 Total profit = 13

- path to terminal node 10—the company would prepare the bid and would make the short list, but their bid of \$155K would be unsuccessful

Total cost = 10 + 5 Total profit = -15

- path to terminal node 11—the would company prepare the bid and would make the short list, and their bid of \$170K would be accepted

Total cost = 10 + 5 + 127 Total revenue = 170 Total profit = 28

- path to terminal node 12—the company would prepare the bid and would make the short-list, but their bid of \$170K would be unsuccessful

Total cost = 10 + 5 Total profit = -15

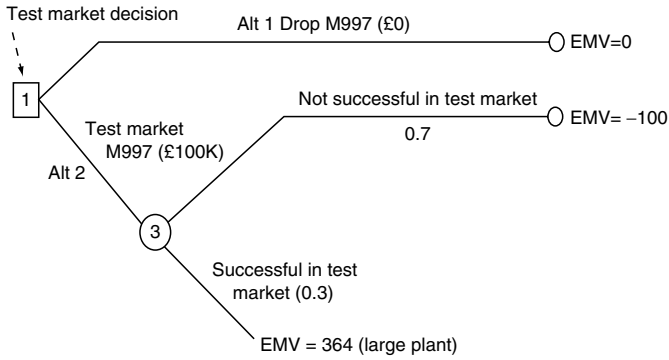

Figure 47-6 Revised decision tree to determine plant size.

- path to terminal node 13—the company would prepare the bid and would make the short-list, and their bid of \$190K would be accepted

Total cost = 10 + 5 + 127 Total revenue = 190 Total profit = 48

- path to terminal node 14—the company would prepare the bid and would make the short-list, but their bid of \$190K would be unsuccessful

Total cost = 10 + 5 Total profit = -15

- path to terminal node 15—the company would prepare the bid and would make the short-list and then would decide to abandon bidding (an implicit option available to the company)

Total cost = 10 + 5 Total profit = -15

Hence one arrives at Table 47-2 indicating for each branch the total profit involved in that branch from the initial node to the terminal node.

One now can carry out the second step of the decision tree solution procedure whereby one works from the right-hand side of the diagram back to the left-hand side.

Step 2

Consider chance node 4, with branches to terminal nodes 9 and 10 emanating from it. The expected monetary value for this chance node is given by $0.90(13) + 0.10(-15) = 10.2$

Similarly, the EMV for chance node 5 is given by $0.75(28) + 0.25(-15) = 17.25$

The EMV for chance node 6 is given by $0.35(48) + 0.65(-15) = 7.05$

Hence, at the bid-price-decision node, we have four alternatives:

1. Bid \$155K EMV = 10.2
2. Bid \$170K EMV = 17.25
3. Bid \$190K EMV = 7.05
4. Abandon the bidding EMV = -15

Hence, the best alternative is to bid \$170K, leading to an EMV of 17.25.

Hence, at chance node 2 the EMV is given by $0.50(17.25) + 0.50(-10) = 3.625$.

Hence, at the initial decision node, we have the two alternatives:

1. Prepare bid EMV = 3.625
2. Do nothing EMV = 0

Hence, the best alternative is to prepare the bid leading to an EMV of \$3625. In the event that the company is short-listed, then (as discussed above) it should bid \$170,000.

Queuing Theory and Simulation

“Mathematicians do not study objects, but relations between objects. Thus, they are free to replace some objects by others so long as the relations remain unchanged. Content to them is irrelevant: They are interested in form only.” Jules Henri Poincaré (1854–1912)

The Hotline Problem

The use of queuing theory is used in a variety of ways to solve waiting-time problems. Typically there is the multiline/multiservice model that is similar to several lines of cars lining up at a gas station or information going to a printer queue. Other types, such as single-line/multiservice or multiline/sequential multiservice, can be described as well. Other factors, such as fixed or variable service times or random or fixed arrival times, enter into these problems. There are a number of basic mathematical algorithms that can be used to determine the probability distribution of waiting time (e.g., 5% wait >20 min., 10% wait <2 min.) The current method used in solving these and other problems utilizes software not unlike simulating electronic circuit configurations or flight simulators. Following is an example of setting up a telephone hotline center for a health care institution. Other applications will be intuitively obvious.

A hospital is planning to set up a cancer hotline center and needs to know the required staffing level to process calls. The I/ME conducts a series of trial calls to determine the expected mean time (and standard deviation) that it would take to process each call (service time). Research in gathering data at other similar centers reveal that, on average, 67% of the calls come in the a.m. and 23% in the p.m. and that calls arrive randomly.

In simulating this problem, the operation was simulated varying the daily volume and the number of operators. The service time was 3.8 minutes and considered exponential in that some calls may be extremely long. The results of the simulation are presented in the following table:

Table 47-3 represents relationships among daily call volume, the number of nurses answering the phone, the number of rings before the call is answered, and the productivity. Within each cell, under “Pickup,” is the percentage of the time that someone will pick up the call, at a 95% confidence level, within the corresponding number of calls. For example, at the 80-calls-per-day level, one could be 95% sure that, with two nurses, a call would be picked up within 5 rings 87% of the time, or within 7 rings 91% of the time. The productivity level with two nurses would be 36%. Now, the manager must make a decision based on service level and productivity. The manager could decide to forego productivity for better service, or vice versa. These simulation techniques can be applied to queuing models and are valuable in determining quality-service levels.

Table 47-2 Total profit for each branch from the initial node to the terminal node

Terminal node	Total profit \$
7	0
8	-10
9	13
10	-15
11	28
11	-15
13	48
14	-15
15	-15

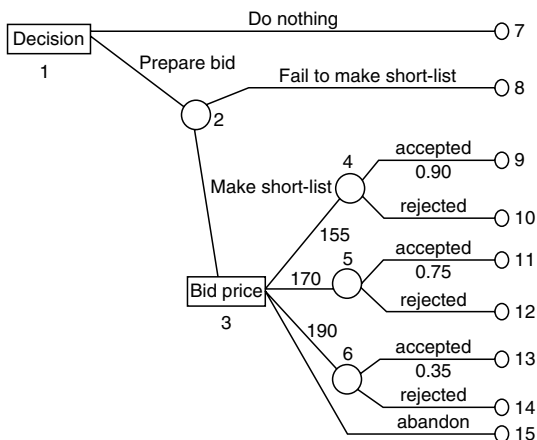

Figure 47-7 Decision tree to determine whether or not a company should bid for a certain contract.

Table 47-3 Relationships among daily call volume, the number of nurses answering the phone, the number of rings before the call is answered, and the productivity

Calls/day	Nurses	95% Conf. pick-up within				Productivity
		3	5	7	<=10	
60	1	88	93	96	>98	54%
60	2	94	97	99	>99	27%
60	3	97	98	99	>99	18%
80	1	82	86	88	>92	72%
80	2	84	87	91	>95	36%

100	1	75	78	81	>83	90%
100	2	77	79	84	>87	45%
100	3	80	84	89	>94	30%

Cost-Benefit Analysis

"Informed decision making comes from a long tradition of guessing and then blaming others for inadequate results"—Scott Adams

As budgetary issues grow in complexity and pressures increase for medical organizations to remain fiscally sound in the face of increasing regulation, cost-benefit analysis offers decision-makers a potentially potent source of counsel. This decision support tool provides a format for enumerating the range of benefits and costs surrounding a decision, aggregating the affects over time using an approach called "discounting," and arriving at a dollar-denominated "present value" that in concept is comparable with other uses for scarce financial resources.

In order to reach a conclusion as to the desirability of a project, all aspects of the project—positive and negative—must be expressed in terms of a common unit, that is, there must be a "bottom line." The most convenient common unit is money, which means that all benefits and costs of a project should be measured in terms of their equivalent monetary value. A project might provide benefits that are not directly expressed in terms of dollars, but there might be some amount of money that the recipients of the benefits would consider to be just as good as the project's benefits. For example, a project might result in fewer job injuries or in better patient access. In the grossest sense, the value of that benefit to a worker who risks injury is the minimum amount of money that that recipient would take instead of the medical care or that the organization would lose in a negligence lawsuit. This value could be either more or less than the market value of the medical care provided. It is assumed that more esoteric benefits, such as preserving aesthetic space or historic sites, have a finite equivalent monetary value to the organization.

A simple, systematic, and structured approach to apply in supporting business decisions should include the following considerations:

- Which vendor's outsourcing proposal is the best choice?
- Are we better off building or buying the application?
- If we can't pay for all the projects, which ones should we select?
- Are we better off implementing the only option or doing nothing?

Example

A materials management director is deciding whether to implement a new computer-based contact-management and purchasing-processing system. The department has only a few computers and his staff are not computer literate. He is aware that computerized work forces are able to process more requests and to give a higher quality of reliability and service to "customers." They also will be more responsive to their commitments and regulatory requirements and can work more efficiently with inventory control, warehousing, and logistics. The financial cost/benefit analysis is shown below:

Costs:

- New computer equipment:
 - 10 network-ready PCs with supporting software @ \$1225 each
 - 1 fileserver @ \$1750
 - 3 printers @ \$600 each
- Cabling and installation @ \$2300
- Support software @ \$7500
- Training costs:
 - Computer introduction—8 people @ \$ 200 each
 - Keyboard skills—8 people @ \$ 200 each
 - Support System—12 people @ \$350 each
- Other costs:
 - Lost time: 40 man days @ \$ 100/day
 - Lost requisitions through disruption: Estimate: \$10,000
 - Lost requisitions through inefficiency during first months: Estimate: \$10,000

Total cost: \$55,800

Benefits:

- Tripling of mail capacity: Estimate: \$20,000/year
- Ability to sustain telepurchase campaigns: Estimate: \$10,000/year
- Improved efficiency and reliability of follow-up: Estimate: \$25,000/year
- Improved customer service and retention: Estimate: \$15,000/year
- Improved accuracy of customer information: Estimate: \$5,000/year

- Increased ability to manage purchasing effort: \$15,000/year

Total Benefit: \$90,000/year

Payback time: \$55,800/\$90,000 = 0.62 of a year = approx. 7 months

Inevitably, the estimates of the benefit given by the new system are quite subjective. Despite this, the materials management director is likely to introduce it, given the short payback time.

Cost/benefit analysis is a powerful, widely used, and relatively easy tool for deciding whether to make a change. To use the tool, first work out how much the change will cost to make. Then calculate the benefit you will derive from it. Where costs or benefits are paid or received over time, calculate the time that it will take for the benefits to repay the costs. Cost/benefit analysis can be carried out using only financial costs and financial benefits. However, one might decide to include intangible items within the analysis. As one must estimate a value for these items, this process inevitably brings an element of subjectivity into the process.

The I/ME Education

"Students today depend too much upon ink. They don't know how to use a pen knife to sharpen a pencil. Pen and ink will never replace the pencil."—National Association of Teachers, 1907

The industrial engineering curriculum prepares engineers to design, improve, install, and operate the integrated systems of people, materials, and facilities needed by industry, commerce, and society. Industrial engineers solve problems that arise in the management of systems, applying the principles of engineering science, product/service and process design, work analysis, human factors principles, and operations research.

The typical industrial engineering curriculum combines four professional areas of practice: Product and production process design, work analysis, decision sciences, and engineering-management science. Students also are offered exposure to the more specialized areas of automated manufacturing systems, information systems, quality management, operations research, and safety engineering. In the freshman and sophomore years, a two-year foundation in basic sciences, engineering science, mathematics, the humanities, and the social sciences is taught to provide an adequate background for the courses presented in the following years. The last two years focus on developing expertise in statistics, operations research, information systems, systems analysis, organizational management, manufacturing, and industrial engineering methods. Courses stress fundamental principles and concepts that culminate in a system design dealing with real engineering and management situations in an industrial, commercial, or public-service enterprise. Students take required and elective courses that are relevant to their chosen major. Some of these courses are listed below:

- Introduction to Telecommunication Service and Systems
- Computer Simulation
- Decision Analysis
- Engineering Aestho-physiology
- Engineering Economy and Cost Analysis
- Engineering Statistics I
- Engineering System Design
- Facilities Planning and Design
- Management Organization Theory
- Operations Research I
- Operations Research Software Studies
- Product Development and Product Information Management
- Production Management I
- Quality Control
- Regression Analysis and Experimental Designs
- Statistical Data Analysis
- Work-Cell Programming for Factory Automation
- Human-Computer Interaction Design

Professional Organizations

A number of professional organizations help I/MEs to maintain their professional skills and to keep up with the latest problem-solving techniques that their peers have learned and applied in a particular specialty. One major web-access page is:

TechExpo—Directory of Hi-Tech Organizations for the Engineering and Medical/Life Sciences: http://www.techexpo.com/tech_soc.html

Other societies that are specific to the area of industrial/management engineering include the following:

- Society for Engineering & Management Systems
- Society for Health Systems
- Society for Work Science (Ergonomics & Work Measurement)
- Aerospace & Defense Division
- Energy, Environment & Plant Engineering Division
- Engineering Economy Division
- Facilities Planning & Design Division
- Financial Services Division
- Logistics Transportation & Distribution Division
- Manufacturing Division
- Operations Research Division
- Quality Control & Reliability Engineering Division
- Utilities Division

- Computer & Information Systems Interest Group
- Consultants Interest Group
- Electronics Industry Interest Group
- Engineering Design Interest Group
- Government Interest Group
- Process Industries Interest Group
- Production & Inventory Control Interest Group
- Retail Interest Group

Conclusion

“Coming together is a beginning, staying together is progress, and working together is success.”—Henry Ford

This chapter has acquainted the clinical engineering professional with the field of industrial/management engineering. Collaborating with a management engineering professional yields the benefits of developing a comprehensive approach to planning, problem-solving, and decision making. Many professionals fear loss of ownership for a particular assignment and are apprehensive about multidisciplinary partnerships that can lead to conflicts in leadership, approach strategy, and solution determination. However, these partnerships are necessary to effectively meet a progressively complex, technology-driven, austerity budgetary environments. Further, it challenges the engineering professional to approach these issues as part of a knowledge-expert team.

Having graduated from college and having been hired as a clinical engineer at a hospital, one day the CE is seated next to the chief operating officer (COO) at a business lunch. The CE knows that the COO started as a transporter 30 years ago and that he rose through the ranks of the organization to his current position. The COO believes that a person only needs (innate) ability and experience in order to succeed in business. What arguments would the CE use to convince the COO that the decision making techniques performed by a CE and an I/ME are valuable?

The points to consider should include:

- Engineering analyses are obviously valuable in tactical situations where data are well-defined.
- The advantage of explicit decision making is that it allows assumptions to be examined explicitly.
- That an “analytical” approach might be better (on average) than a person.

- CE and I/ME techniques combine the ability and experience of many people.
- Sensitivity analysis can be performed in a systematic fashion.
- CE and I/ME techniques enable problems that are too large for a person to tackle effectively to be dealt with.
- Constructing an engineered model structures thought about what is and is not important in a problem.
- Training in engineering teaches a person to approach problems in a logical fashion.
- Using standard CE and I/ME techniques prevents the need to “reinvent the wheel” each time a person meets an appropriate problem.
- Modeling techniques enable computers to be used with (usually) standard packages and, consequently, all benefits of computerized analysis (e.g., speed, rapid [elapsed] solution time, and graphical output).
- CE and I/ME techniques complement ability and experience, not substitute for them.
- Other companies use engineering techniques: Do we want to be left behind?
- Ability and experience are vital, but CEs and I/MEs to use these effectively in tackling large problems.
- CE and I/ME techniques free executive time that could be spent on more creative tasks.

Financial Management of Clinical Engineering Services

Binseng Wang

Senior Director, CE & QA, MEDIQ/PRN Life Support Services, Inc.
Pennsauken, NJ

48

One of the intrinsic and fundamental components of the successful management of clinical engineering services is financial management. Unfortunately, many managers have overlooked the importance of financial management. For the last decade, American health care organizations have been under increasing pressure to contain and reduce costs in all areas, including the support services for medical equipment. This pressure has resulted in the contraction or even the demise of many in-house clinical engineering departments that were not able to prove their cost-effectiveness or competitiveness against independent service organizations or multivendor service divisions of major manufacturers. In reality, the financial management skills required are fairly elementary and well within the grasp of persons with strong technical background and mathematical proficiency. To illustrate the way an in-house clinical engineering department would manage its finances, a hypothetical example for a small community hospital is provided here. This example starts from an annual budget that includes all of the typical expenses and overhead and ends with an analysis of the principal components of the cost of service. Through this analysis, the manager will be able to determine the best opportunities for improving the department’s cost-effectiveness and competitiveness. On the other hand, if the clinical engineering services are part of a for-profit enterprise, the financial-

management skills required are substantially more involved but still within reach of those who are willing to invest some time to learn. A second example is provided, to demonstrate the way a financial plan can be drafted for the first five years of a start-up service company. This example shows the main planning tools (i.e., projected income, cash flow, and balance sheets) as well as an analysis of the viability and performance of the enterprise. Using these tools, the company’s management can plan and monitor progress and can seek funding from venture capital firms and lending organizations to transform the business from a “garage operation” into a *Fortune* 500 company (assuming a little bit of luck!).

Introduction

“Just about everything that we do involves allocation of resources.”
—Marvin Minsky, professor and director, Artificial Intelligence Lab, Massachusetts Institute of Technology, Cambridge, MA (Minsky, 2001).

Although the statement above was made in the context of research on the human thinking process, it holds true for most human endeavors and certainly for clinical engineering (CE) activities. Among the various resources that must be allocated and therefore properly managed, financial resources are among the most prominent. Unfortunately, financial management is often poorly understood and frequently ignored by CE practitioners, especially in the United States. Multivendor service companies successfully exploited this weakness in the last decade, which led to the contraction and demise of many in-house CE departments. In developing countries, the need to justify their existence in financial terms is generally better understood by the clinical engineers, although only a few of them have published their achievements (see, e.g., Wang & Bellentani, 1986).

During its infancy in the U.S. (i.e., the 1960s and 1970s), CE growth was stimulated primarily by a fear of liability and a desire to improve health care quality. Money was of little concern. The quality of equipment manufactured was often poor, so hospitals were willing to invest in CE to ensure quality and to reduce risks. The CE departments were managed by persons who had strong technical backgrounds but little or no business management training or experience. Some of the clinical engineers learned how to manage the finances of their department or company, but most had been reluctant to meet this challenge head-on. This scenario changed significantly in the later part of the 1980s and profoundly in the 1990s because of the nationwide cost-containment and reduction efforts. Except for a few prestigious hospitals, most health care organizations were under enormous pressure to reduce their costs while improving their quality. CE departments had to prove their cost-effectiveness in order to survive in this new environment. Initially, benchmarking was used as a way to compare efficiency among hospitals and against some outsourcing companies. One of the common financial benchmarks was the cost of the CE department as a percentage of the total cost of the equipment. As discussed by Cohen et al. (1995), this parameter depends very much on the types of equipment covered. For example, the percentage cost is much higher for the CE departments that do not cover imaging equipment than it is for those that provide maintenance to big-ticket items such as X-ray machines and CT scanners. For this benchmark to be meaningful, it is mandatory to compare the total equipment-support cost with the total equipment-inventory cost (Cohen et al., 1995). Unfortunately, because many CE departments do not cover imaging equipment, there is no way for them to use this benchmark to gauge their efficiency.

Over the last decade, multivendor service companies have begun to emphasize hourly rates and total maintenance costs when they have pitched their services to health care organizations. Even though these parameters are also imperfect benchmarks, they are easier for the hospital administrators to understand because of their MBA training. Therefore it is essential for the CE managers to know how to calculate their hourly rates or total department costs in order to remain competitive (or to keep their jobs!). One of the benefits of learning how to calculate these values is in understanding what the most important factors of a department's costs are and therefore how they can be reduced or eliminated.

This chapter addresses the principles and practices of financial management by analyzing two fictitious, but realistic, examples. The first case is that of a small, in-house CE department that is responsible for the management of all of the medical equipment—including imaging and clinical laboratory—but not the facilities. This in-house team performs repairs and preventive maintenance on equipment for which it has technical competence, and supervises service contracts for equipment on which it lacks expertise. By analyzing its annual budget and ways in which the institution can fund this department, insight into ways to manage its finances is gained. Furthermore, whether this department has any chance of fighting off an assault from outsourcing companies is discussed.

The second case study analyzes the finances of a small CE service company. This company is a for-profit business that was started in order to provide maintenance and consulting services to the hospital mentioned above, and that subsequently grows to provide the same services to other health care organizations in its vicinity. The goal here is to see how much profit this company must generate in order to survive its first five-year period.

By comparing these two case studies, we are able to understand the challenges and opportunities that each organizational structure has. Furthermore, it is hoped that this comparison will help those who want to progress from an in-house team into a shared-services organization, or even into a for-profit independent service organization (ISO).

Although the values used in these case studies are realistic, many details were ignored, and some simplifications were made in order to reduce the complexity of the calculations. All of the illustrations were originally calculated using a computerized spreadsheet. Readers are encouraged to construct their own spreadsheet models and to change the values to resemble their own local realities. This helps to improve understanding of the relative importance of each variable and, therefore, helps in finding opportunities to improve management of finances.

Financial Management for CE Departments

"If you're not in the hunt on cost, you're not going to have the opportunity to demonstrate quality."—Harley Warren, Equipment Asset Manager at Baptist Memorial Hospital, Pensacola, FL (Forrest, 1997).

One of the basic duties of any department manager is to produce an annual budget and then try to control the expenditures within that budget. In this case study, we start by examining the budget of a small CE department composed of the following full-time staff:

- One clinical engineer who spends a portion (60%) of his/her time managing the department while still performing hands-on maintenance services
- Three biomedical technicians (BMETs) whose primary responsibility is to support technology by such means as performing inspections, repairs, and preventive maintenance (PM) and by providing user training
- One administrative assistant who provides all administrative support

This team is responsible for all technical support in the hospital (called "General Hospital"), servicing whatever it can, and managing what is serviced by others (e.g., OEMs and ISOs). The CE department also supervises the service contracts that have been made for some equipment (e.g., imaging and clinical lab). Although it is not really necessary, it is assumed that their employer is a nonprofit, community hospital with approximately \$10 million worth (in terms of replacement cost, not original acquisition cost) of medical equipment (including imaging, clinical laboratory, and biomedical), with a total unit count of 2,500 medical devices. As these values are totally hypothetical, no attempt is made to use them for comparison with actual hospitals.

It is further assumed that this CE department has been in existence for some time, so it is not necessary to purchase all test and measurement equipment. However, it will be necessary to acquire some items, either to replace those that are worn out or to gain additional technical capabilities.

Budgeting

With the assumptions stated above, the budget for the CE department is discussed. A typical expense budget is divided into two parts: One for capital investment, and another for operating expenses.

To assist future analysis and discussion, the concepts of "direct costs" and "overhead" are introduced. Direct costs are those that can be traced to a particular product or service, such as repair parts used for a specific medical device, a maintenance contract for a particular system, hours of time that a BMET spent on performing certain PM functions, and repair fees paid to an ISO for a certain device. On the other hand, overhead includes money spent on tools and supplies that are used for multiple medical devices, training courses for the BMETs, calibration of test equipment, and the time that the clinical engineer and BMETs spent in CE department meetings. Overhead is often confused with fixed costs because the latter are included in the former, but overhead also includes variable costs, such as those for lubricants and medical gases used in equipment service, that increase with the amount of equipment serviced. In other words, overhead is the sum of fixed costs and the portion of variable costs that cannot be easily (or is not worthwhile to be) attributed to individual medical devices. This distinction is shown to be important later in this chapter, when funding alternatives are discussed.

Table 48-1 shows the annual budget for the CE department for the fiscal year of 2001. The values in this table are explained below in detail. It suffices to point out that the total budget is \$454,530, of which \$285,300 corresponds to direct costs, and the remaining \$169,230 to overhead.

Capital Investment

As stated before, it is assuming that this CE department has been in existence for some time, so it is not necessary to purchase a complete set of new test and measurement

Table 48-1 Sample annual budget for a clinical engineering department

<i>General Hospital Clinical Engineering Department Annual Budget For Fiscal Year 2001</i>			
	Total (us\$)	Direct	Overhead
1. Capital Investment	\$8,480	\$0	\$8,480

2.6.2 Energy	\$450		\$450
2.6.3 Medical Gases	\$250		\$250
2.6.4 Mail	\$200		\$200
2.6.5 Professional Associations	\$600		\$600
2.6.6 Physical Space (rent)	\$7,500		\$7,500
2.6.7 Miscellaneous	\$15,050		\$15,050
Total	\$454,530	\$285,300	\$169,230

equipment. On the other hand, one assumes that it will be necessary to acquire some items, either to replace those that failed or to gain additional technical capabilities.

Table 48-2 shows the capital-investment budget. Note that the list includes many medical devices that already are in the inventory (i.e., those with quantity equal to zero). These existing items and their respective values will be used later (in section 3.1.3) for depreciation calculations. Most of the items are self-explanatory and low-cost. One exception is the allowance for magazines and periodicals. This is because some subscriptions are rather expensive (e.g., ECRI's *Health Devices* costs about \$2000 per year).

Operating Expenses

Like other organizations within the service industry, CE departments typically have operating expenses that are much higher than the capital investment. There are many ways to classify operating expenses, each with its own advantages and disadvantages. For simplicity and didactic reasons, as few classifications as possible are used—only enough to visualize the most important components and to avoid missing important expenditures.

Table 48-3 shows an example of an operating budget. Here, again, not only the values are provided but also the breakdown between direct expenses and overhead. Each of the main items is explained below.

Personnel and Benefits As explained above, the CE department is composed of the following full-time staff:

- One clinical engineer
- Three biomedical technicians (BMETs)
- One administrative assistant

For simplicity, it is assumed that the three BMETs earn the same annual salary, such as \$31,000. An allowance is made for 10% overtime for the hourly-paid employees; i.e., all except the clinical engineer. In addition to their salaries, the costs of the benefits mandated by law (e.g., state unemployment contribution by employers) and voluntarily provided by the employer (e.g., partial coverage of health, dental, and life insurance premiums) must be considered. Furthermore, it is important to make allowance for overtime and, often, on-call charges. For simplicity, these two charges are bundled into a single value. Table 48-4 shows an example of the personnel-expense budget. The values on this table were arbitrarily chosen and are probably low for major metropolitan areas, but reasonable for small cities. Readers are welcome to recalculate the values using numbers that are more realistic for their individual cases.

Supplies Included in this budget category are replacement parts, maintenance supplies, and office supplies. The distinction between replacement parts and maintenance supplies is somewhat arbitrary but necessary to distinguish between parts e.g., printed circuit boards (PCBs) and pneumatic subassemblies, used for specific medical devices and those that can support multiple medical devices (e.g., a tube of lubricant or a package of nuts and bolts). Often, many items that could be traced to individual devices are simply accounted for in bulk as maintenance supplies, simply because their low costs do not

Percentages	100%	64%	36%

justify the labor associated with detailed accounting. Included in the office-supplies category are such items as paper, notebooks, pens, and clips. Again, the values chosen in Table 48-3 are probably on the low side, but they suffice for this case study.

Third-Party Services Included within this category are all the expenses that are paid to an entities outside of the hospital for delivering such items as maintenance contracts, maintenance services, training of BMETs, consultant services, calibration of test equipment, and printing of service-report forms used to record services performed. Naturally, there could be more or fewer expense items in individual cases. Again, the values in Table 48-3 were chosen arbitrarily but they reflect the reality of a community hospital.

Because the service contracts and time and materials expense can be traced to individual medical devices, they have been classified as direct expenses. The rest should be spread out evenly among all of the equipment covered by the CE department and, therefore, it is considered overhead.

Freight & Travel This category includes allowances for the incoming shipment of maintenance materials (i.e., parts and supplies) and outgoing shipment of equipment for service elsewhere. Also included in this category are the travel expenses associated with training. In this case, two trips are being planned. Note that the training cost (tuition) was already included in the previous category. The values chosen for the items of this category are shown on Table 48-3.

Other Operating Expenses Included in this category are all the other expenses that were not included in the previous categories and for which specific categories were not desired. Table 48-3 shows some common examples. As most of them are self-explanatory, no attempt is made to describe each one. However, facilities (e.g., physical space, energy, and gases), provided by the health care organization are included. It is important to

Table 48-4 Sample of annual personnel-expense budget for a clinical engineering department.

<i>General Hospital Clinical Engineering Department Personnel Expenses Details</i>

TOTALS			\$240,400	\$120,300	\$120,100

account for these “invisible” costs, to make any calculation and comparison realistic. An allowance for small variances and oversights is included as “miscellaneous,” which is assumed to be 5% of the total operating cost.

Financing Alternatives

There are several ways to cover the total annual budget of \$454,530 for the CE department. Each of these methods is briefly described and discussed below.

Cost Center

One of the most common and traditional methods is to consider the department a cost center within the organization’s administrative budget. In other words, the CE department is part of the overhead that all the revenue-generating departments must support. Examples of other administrative departments are finance, information technology, and human resources. The head of CE department—in this case the clinical engineer—negotiates the department’s annual budget with his/her supervisor and then tries to “live” within this constraint. The budget is composed of capital investment and operating expenses. (See the top section of Table 48-5.) Section 2.3.1 discusses the way the clinical engineer should analyze the budget in order to become more cost-effective and to increase the value of the department to the employer.

Cost-Sharing

Another method is to make each user department (e.g., ICU, surgical center, and cardiology) pay a certain percentage of the CE department’s budget. The percentages contributed by different departments are pre-established and typically are commensurate with the amount of services that they receive from the CE department.

The user departments (e.g., psychiatry) that have fewer medical devices prefer this method because they pay less than they would in the cost center method, where all revenue-generating departments contribute equally, regardless of the usage. The departments that have more equipment (e.g., imaging, cardiology, and surgery) will have to contribute more because of their frequent use of the services provided by the CE department.

While this method may be “fairer” than the previous one, the head of the CE department must be careful not to bias his attention toward the heavier users (“bigger customers”), ignoring the less frequent users. To do so could create a politically dangerous situation.

Reimbursement for Service

Yet another financing method is reimbursement (or “chargeback”) for service performed. The CE department “charges” each user department monthly (or quarterly) for the material and labor provided to that department. Typically, the CE department computes the hourly labor rate that will need in order to cover all of its direct costs and overhead, and it then multiplies the number of hours provided to each department by this labor rate. To this rate, the CE department adds the “pass-through” costs, i.e., those costs that are spent for specific medical devices (or department).

The middle section of Table 48-5 shows the reimbursement values for our case study. In this case, the “pass-through” costs are the maintenance contracts, time and materials, third-party services, and replacement parts. The difference between the annual budget and these “pass-through” costs are called “non-pass-through expenses” that must be recovered through reimbursement. To these expenses must be added the depreciation of capital investment (assumed at the rate of 10% per year), to build reserve for replacing test and measurement equipment in the future. Therefore, the total to be reimbursed is \$286,482. In order to derive the hourly labor rate, the total number of productive hours that the CE department is capable of generating must be determined first.

Table 48-6 shows the way the total number of productive hours is calculated. First, the holidays, vacations, and sick days and other paid absences (e.g., jury duty, bereavement leave, and training) must be subtracted from the total number of paid working hours. The number thus calculated is called “hours available for work.” Each worker must take some breaks for refreshments, toilet use, walking to user departments, or helping a user or colleague, so not every available hour can be used to service equipment. The productivity for BMETs is typically in the range of 70%–85% (Furst, 1997). In this case study, a productivity of 75% is assumed. Furthermore, it is assumed that the clinical engineer can contribute only 40% of his or her total time to hands-on work; the rest is spent on meetings and administrative duties. Therefore the total number of productive hours per year for the entire CE department is 4671.6 hours.

Returning to the middle section of Table 48-5, with this value, the hourly labor rate to charge for reimbursements is \$61.

This financing method is more laborious than those previously presented, but it has the advantage of providing user departments with an accurate accounting of the services provided. This helps to reduce the number of unnecessary service calls, but the labor involved in the accounting ultimately may reduce the productivity of the CE department.

It is possible to carry the reimbursement model further and to compute the actual cost associated with each activity. This type of accounting is known as “activity-based costing” (ABC) (Marchese, 2001). For example, in our case study, one could separate the PM activities from the repairs. If the three BMETs have different levels of expertise and are paid at different rates, the CE department manager might assign the PM duties to the least experienced person and might let the more experienced BMETs perform the more challenging repairs. In this case, the cost of PM activities could be billed at a lower rate than repairs. This accounting method is valuable when there is a large enough difference in staff pay to justify the accounting time invested.

Profit Center

An astute CE department director can actually use the reimbursement model to his advantage and to become profitable. By calculating precisely the hourly labor rate and carefully controlling the expenses, it is possible to generate some budgetary surplus, which then

Table 48-5 Examples of three financing methods for a clinical engineering department: (1) as a cost center; (2) through reimbursement per service; and (3) as a profit center

<i>General Hospital Clinical Engineering Department Financing Methods</i>	
	<i>Value</i>
1. Cost Center

Total Number of Productive Hours	4671.6 hours
Hourly Labor Rate to be Charged to Customers	\$77
Management Fees over Pass-Through Costs	\$24,750
Management margin	15%
Total Profit (before taxes)	\$96,371

can be used to buy more tests tools or training courses or to improve the work environment. However, this approach must be used with great care, preferably with explicit approval of the organization. Furthermore, the CE department must be attentive in not overemphasizing its profit because this could prevent it from being competitive when it is compared to the outside service providers, especially the ISOs. Moreover, other departments could become jealous and create political troubles.

Alternatively, a real for-profit service operation can be set up (even under the umbrella of a nonprofit organization). The bottom section of Table 48-5 shows the way this enterprise would have to calculate its hourly labor rate. Assuming, arbitrarily, that the desired

Table 48-6 Sample calculation of the total number of productive hours per year for a clinical engineering department

<i>General Hospital Clinical Engineering Department Productivity Analysis</i>		
	<i>Values</i>	<i>Hours</i>
Hours Paid per Employee		
Hours/week	40	
Weeks/year	52	
Total		2080

Productive Hours per Year		1374
For each biomedical technician		
As a percentage of paid hours	66%	
Total Number of Productive Hours for the Clinical Eng. Dept.		
Number of biomedical technicians	3	
Percentage of hands-on time for the clinical engineer	40%	
Total number of productive hours/year		4671.6

profit margin is 25% (over the cost), the hourly rate for the same CE department would rise from \$61 to \$77. In addition, it is likely that it will also add a management fee to the pass-through costs (after all, someone has to spend time to supervise what the third parties are doing). For our case study, we will assume that 15% will be added. Therefore the total profit that this service center will generate per year would be \$96,333. The next section examines whether the assumptions of a 25% profit margin and 15% cost markup are enough to keep this business model afloat.

Naturally, a combination of the methods mentioned above also can be used in a single organization. It also should be stressed that the same financing method does not necessarily work best for all organizations of similar size and complexity. Each one might have a different financing method that is preferred within that institution, and the CE department is required to follow that model.

Discussion

Now that budget creation has been reviewed, the most important factors, and the ones that we can manipulate to improve the CE department’s competitiveness, are to be identified and analyzed.

Budget Analysis

First, the overall budget (Table 48-1) is analyzed in two ways: By comparing capital investment with operating costs, and by comparing direct costs and overhead. As stated above, in being a service organization, the CE department spends most of its budget on operating expenses rather than on capital investment. Table 48-7 shows that, in our case study, the operating expenses form 98% of the budget, while capital investment accounts for only 2%.

More interesting is to look at the relative proportions of the direct costs versus overhead. In the budget shown in Table 48-1, direct costs are 63% of the total budget and overhead is 37% (see item 2a of Table 48-7). However, if the user departments were to pay directly for the service contracts and third-party services (which happens in many hospitals in the United States), the overhead would jump to 55% (see item 2b of Table 48-7). If the user departments also were to pay for the replacement parts, the overhead would become almost 50% larger than the direct costs (item 2c of Table 48-7), even though nothing has changed in reality. This explains why the CE departments are often perceived as being inefficient; they spend most of their budgets on nonproductive work. The CE department director must be able to explain that this number manipulation hides the fact that the CE department spends time and energy supervising service contracts and third-party services and replacing failed parts with new ones. In other words, the CE department is adding value to those services and replacement parts and, therefore, should be entitled to include these expenses when computing the overhead.

Another way to visualize the relative importance of different components of the budget is to put them into a pie chart. Figure 48-1 shows that the main components of the budget are labor (26%), overhead (37%), and maintenance contracts (26%). The rest, third-party services (6%), parts (4%), and supplies (1%), add up to a total of only 11%. Included in the overhead are capital investment, freight, travel, and other operating expenses, in addition to the indirect personnel expenses and benefits.

Cost Analysis

The hourly labor rates that the CE department charges the user departments are now addressed. From Table 48-4 (personnel budget) we can see that the total direct cost of labor is \$120,300. If this value were divided by the total number of productive hours, the hourly rate for productive labor would be obtained. Table 48-8 shows that the result is \$26 per hour. Subtracting this value from the reimbursement hourly rate of \$61, the hourly rate for overhead is \$36 (rounded up from \$35). In other words, only 42% of the hourly rate of \$61 is actually used to pay for work that is directly related to maintenance, while the remaining 58% is for overhead. Again, this is a somewhat distorted way of viewing the facts, as the amount of \$120,300 cannot buy all of those productive hours. For example, without the benefits, one simply cannot get the employees to work. It is also illegal not to pay mandatory benefits.

Nonetheless, it is clear from this simple analysis that one must carefully control the overhead. Any activity that is not directly related to the production of services, i.e., overhead, will increase the hourly labor rate that the CE department needs to charge to the user departments without bringing tangible benefits to the latter. A closer look at Table 48-4 will show that the situation would improve significantly if the ratio of hands-on personnel versus administrative personnel increases. This fact explains why larger CE departments, OEMs, and ISOs have advantage over smaller CE teams. This is the reality of economies of scale.

Table 48-7 Analysis of the overall budget by comparing capital investment and operating costs, and by comparing direct costs and overhead in various scenarios

Budget Analysis	Capital	Operating
1. Comparison between capital investment and operating costs	2%	98%
2. Comparison between direct and overhead	DIRECT OVERHEAD	
2a. With everything	\$454,380	\$283,800
percentage	100%	63%
2b. Without service contracts & 3rd-party services	\$309,530	\$140,300
percentage	100%	45%
2c. Without replacement parts	\$289,530	\$120,300
percentage	100%	42%

Figure 48-1 Main components of the annual budget for a clinical engineering department

Competitiveness Improvement

One natural way to improve competitiveness would be to improve the quality of services by, for example, reducing the amount of “rework” (e.g., repeated repairs). In spite of its obvious importance, this does little to decrease the hourly labor rate. There are at least three possible ways to decrease this rate. As shown in Table 48-9, the first possibility is to increase the productivity to 80%, which would increase the amount of productive hours and would reduce the labor rate to \$57 per hour. The second option would be to decrease the overhead by 10% by for example reducing the amount spent on external consulting and travel and by negotiating the training costs into the initial equipment-acquisition price. This would reduce the labor rate to \$58 per hour. If one could simultaneously increase productivity and reduce overhead, it would be possible to reduce the labor rate to \$54 per hour. The eternal challenge for all CE department managers is in decreasing costs while improving the quality of services.

Financial Management for CE Service Providers

“Know yourself and your enemy, and you will win one hundred percent of your battles.” –Sun-Tze, ancient Chinese war strategist

As it is often said, business is war. In order to survive and thrive in any business, one must know how to control its finances, especially its costs. In other words, know your costs and those of your competitors, and you will win and prosper.

Unfortunately, it is not enough to know how to prepare a budget and to operate within its limits. Quite a few additional financial concepts are needed. Readers might want to consult some textbooks on business accounting (e.g., Siegel et al, 1987; Anthony, 1997; Fridson, 1996; and Brigham and Houston, 1998) in order to appreciate fully the case study presented below. There are also a number of business-accounting software programs, such as Peachtree™ Complete Accounting and QuickBooks™ by Quicken™. These programs allow a small business to manage its finances without a full-time accountant, and they have some examples and tutorials that are worth examining.

Financial Planning

One of the fundamental differences between managing a cost center versus a business enterprise is the need to look at the relations between income and expenses for a certain period of time (typically five years). This long-range planning is necessary in order to visualize the ultimate self-sustainability of the enterprise as well as the potential return on the investment of capital and time. If the long-term prospect is not good, or if the return on investment (ROI) is not promising, there is no reason to waste time and money. It would be better to put the money in a bank and to enjoy life on the beach.

The following case study concerns a service company called “Fix-All Biomed Company,” which is composed of the people who were in the CE department described in the previous case study:

- One clinical engineer, who spends a portion (60%) of his/her time managing the department while still performing hands-on maintenance services
- Three BMETs, whose primary responsibility is to support technology (i.e., to perform inspections, repairs, PM, and user training)
- One administrative assistant, who provides all administrative support

Table 48-8 Analysis of the labor cost, comparing the direct cost and overhead components of hourly rate

Cost Analysis		
Total cost of productive labor (direct costs in figure 4)	\$120,300	
Total Number of Productive Hours	4671.6	
Hourly labor cost for productive labor	\$26	42%
Hourly labor cost for overhead	\$36	58%
Total cost of overhead within operating expenses	\$160,750	

Table 48-9 Alternatives for improving the hourly labor rate for a clinical engineering department

Alternatives For Improving Competitiveness	
1) Improve quality	The costs will not change, but less rework may save money.
2) Decrease costs	
a) Increasing productivity to	80%
Total number of productive hours increase	4983
Hourly labor rate for reimbursement decrease	\$57
b) Reduce the overhead by 10%	10%
Total cost of overhead decreases to	\$144,675
Hourly labor rate for reimbursement decrease	\$58
c) Doing both	
Total number of productive hours increases	4983
Total cost of overhead decreases to	\$144,675
Hourly labor rate for reimbursement decrease	\$54

This company has a comprehensive service agreement with the General Hospital described above, with the obligation of servicing whatever it can, and of managing the rest that is serviced by third parties, i.e., OEMs and ISOs. The company also supervises service contracts that it makes for the hospital to maintain certain medical devices (e.g., imaging and clinical lab). Although it is not really necessary, it is assumed that the General Hospital is a community hospital with approximately \$10 million worth (in terms of replacement cost, not original acquisition cost) of medical equipment (including imaging, clinical lab, and biomedical), with a total unit count of 2,500 medical devices. After the first year the company will try to obtain business from other health care organizations within the same geographical area, thereby expanding its revenue base in order to be less dependent on a single customer.

Table 48-10 shows a typical five-year financial plan for the Fix-All Biomed Company. This spreadsheet is organized quite differently from the annual budget shown on Table 48-1. First, it includes income, known as “revenue,” as well as expenditures. The expenses are divided into three categories: Cost of sales, administrative expenses, and financial expenses. The difference between revenue and cost of sales is called “gross income.” From the gross income, one must subtract the administrative expenses and financial expenses to arrive at the net income. The net income could be negative (loss) or positive (profit). If the net income is positive, the company must pay income tax. After the deduction of income tax (assumed to be 35% of the net income), one can see what the company has earned, known as “after-tax net income.” This calculation is projected (or estimated) for a period of five years. The format that is used to present each year’s information is known as an “income statement in accounting.” The other classical accounting reports are the “balance sheet” and “cash flow statement,” which are discussed below.

Each line item on Table 48-10 is explained in detail below, including the way these values change from year to year. As in the case of the CE department budgeting, the values are calculated using many assumptions. Because projections must be made for five years, some of the assumptions could become invalid and would need to be revised fairly soon, or even could need to be totally replaced. Good financial planning depends not only on experience and foresight but also on luck.

Revenue

The revenue shown on Table 48-10 is detailed in Table 48-11. First let us examine the revenue that the Fix-All Biomed Company expects to generate in the first year from its repair services (billed in the form of time spent and material used). In the first year, it expects to generate 3600 billable hours at the rate of \$77 per hour, which is the value previously calculated in Table 48-5 (for a for-profit CE department). The total billable service revenue is then \$297,200. Customers will be billed \$20,000 in replacement parts that can be traced to individual medical devices serviced.

It is assumed that Fix-All will have 10 contracts with individual values of \$12,000 each, totaling \$120,000 of contract revenue. Finally, it is estimated that 40 hours of con-

Table 48-10 Sample five-year financial plan for a clinical engineering service company

1.2 Contracts	\$120,000	\$151,200	\$185,220	\$222,264	\$277,135
1.3 Consulting	\$3,080	\$4,204	\$5,688	\$7,755	\$10,576
2. Cost of Sales	\$264,300	\$301,729	\$315,878	\$398,699	\$519,579
2.1 Pass-through Costs	\$144,000	\$177,820	\$188,252	\$267,244	\$384,181
2.2 Own Expenses	\$120,300	\$123,909	\$127,626	\$131,455	\$135,399
3. Gross Income/profit	\$155,980	\$192,792	\$262,011	\$272,962	\$272,200
4. Administrative Expenses	\$186,348	\$195,731	\$205,714	\$216,367	\$228,490
4.1 Operating Expenses	\$160,750	\$165,573	\$170,540	\$175,656	\$180,926
4.2 Capital Depreciation	\$4,584	\$5,432	\$6,280	\$7,128	\$7,976
5. Financial Expenses	\$6,250	\$6,644	\$5,775	\$4,218	\$3,365
5.1 Interest Received	\$250	\$356	\$225	\$782	\$635
5.2 Interest Paid	\$6,500	\$7,000	\$6,000	\$5,000	\$4,000
6. Net Income/profit (loss)	(\$36,618)	(\$9,582)	\$50,522	\$52,377	\$40,344
7. Taxes 35%	\$0	\$0	\$17,683	\$18,332	\$14,120
8. After-tax Net Income (loss)	(\$36,618)	(\$9,582)	\$32,839	\$34,045	\$26,223

sulting work (e.g., advising hospitals about the brands and models of equipment that are most appropriate for their next purchase) will be provided. At the same rate of \$77 per hour, this consulting work will generate \$3,080 in the first year.

For the subsequent years it is assumed that the number of billable technical hours will increase at the rate of 10% per year and that the cost of replacement parts will increase proportionally to the number of billable technical hours (i.e., more parts replaced due to more work performed). It is also assumed that the hourly rate will increase at the rate of 4% (i.e., 1% above the rate of inflation, which is assumed to be 3% per year). However, the value of service contracts is projected to increase at the rate of 5% because more equipment will be added to each contract. The number of service contracts is assumed to grow at the rate of 20% per year (by contracting with other health care organizations in the same geographical area). Furthermore, Fix-All expects to be able to increase the hourly rate of its consulting services at 5% per year because it believes that its reputation will improve with time; i.e., its customers increasingly appreciate its advice. The number of consulting hours will grow at the rate of 30% per year.

Cost of Sales

Table 48-12 shows the cost of sales that Fix-All expects to have in the first five-year period. These costs are called “cost of sales” because they are a consequence of sales. In other words, if no sales were made, these costs would not exist. They are often known as “variable costs” or “increment costs.” The costs that exist regardless of sales are called “administrative costs” or “fixed costs” and are discussed below. The cost of sales is divided into two main categories: (1) pass-through costs and (2) internal expenses.

The first-year pass-through costs are examined. The first item (2.1.1) is what Fix-All must pay others to perform the work that its own people cannot perform because of the shortage of manpower. From Table 48-6, it can be seen that the maximum number of productive hours is 4672. These hours can be used for repair services, fulfilling contracts, and perform consulting. Any time beyond 4672 hours must be covered by external help (or overtime from internal staff). Table 48-12 shows that the total number of

2.2.1 Personnel	\$120,300	\$123,909	\$127,626	\$131,455	\$135,399
2.2.2 Benefits [<i>see Admin. Expenses</i>]	\$0	\$0	\$0	\$0	\$0

hours available for repair services drops progressively with time as Fix-All absorbs more and more third-party contracts and consulting services. The hourly rate that Fix-All must pay for temporary help is assumed to be \$100 per hour, and it increases at the rate of 5% per year. This rate is higher than the rate Fix-All charges its customers because of the temporary nature and the fact that the company is not paying benefits to the subcontractors.

The second item is simply the cost of replacement parts for which Fix-All expects to be reimbursed by its customers. The third item is composed of maintenance contracts that Fix-All must maintain with OEMs and ISOs because of the lack of expertise or specialized equipment. It is assumed that initially all contracts are simply passed through to third parties (i.e., with no administrative charges from Fix-All). After the first two years, Fix-All's staff learns how to perform some of the work itself and gradually takes over some of the contracts. Each contract is assumed to take 96 hours of labor per year (equivalent to one day per month).

Similarly, the consulting services provided by Fix-All are initially delivered by outsiders. Gradually, Fix-All's staff takes over and keeps the dependence on external experts to a minimum. This keeps the growth of the number of hours to be paid to outsiders at 10% per year.

The second part of the cost of sales is the direct personnel costs, shown in Table 48-4. All overhead is included in the administrative expenses described below. Like the budget for the CE department, it is assumed that the payroll will increase with inflation at the rate of 3% per year.

Looking back at Table 48-10, one can see that the difference between revenues and costs of sales, called "gross income" (or "profit" if it is positive, or "loss" when it is negative), increases steadily with time, giving the impression that the company is growing well.

Administrative Expenses

Table 48-13 shows the administrative expenses anticipated by Fix-All for its first five years. Like the budget for the CE department, these expenses are divided into three main categories:

- Operating costs
- Bad debt
- Capital depreciation (note that this is not capital investment)

Comparing Tables 48-12 and Table 48-3, one can see that all of the operating costs of Table 48-3 that were not included in the costs of sales are included in Table 48-13. For example, the overhead for personnel and all of the benefits from Table 48-3 are transcribed into Table 48-13, as are the costs of supplies, third-party services, travel and shipping, and other operating costs.

Never seen before, however, are the bad debts. These values correspond to the amount of money that Fix-All believes that it might not be able to collect from its clients. While a CE department never has to worry about the hospital not paying for its services (i.e., salaries and benefits to the employees), a private company must make allowance for the possibility that some customers might dispute some of its bills or not pay for its services for whatever reason. In this case, bad debts equal to 5% of account receivables are assumed.

Also included in Table 48-13 are capital depreciation costs that were not considered in the analysis of the CE department. From Table 48-2, the initial investment that was necessary to buy all tools and test and measurement equipment needed to equip the Fix-All Biomed Company (or the CE department) can be computed. This total is \$45,840. Assuming that the company continues to add \$8,480 worth of test and measurement equipment every year, line 4.3.3 shows the growth of the cumulative capital investment over the five-year period. For simplicity's sake, linear depreciation in 10 years is assumed. Therefore, each year, the depreciation of capital investment is 10% of the cumulative investment shown in line 4.3.3 of Table 48-13.

Cash-Flow Projection

Before examining the financial expenses summarized in financial planning (Table 48-10), cash flow projection is explained here. Financial expenses are composed primarily of interest that will be owed on money that is borrowed in order to keep a company solvent. Through cash-flow analysis, one is able to determine how much money the Fix-All

Table 48-13 Sample five-year administrative expenses projection for a clinical engineering company

<i>Fix-All Biomed Company Clinical Engineering Department Five-Year Administrative Expenses Projection</i>					
	<i>Year I</i>	<i>Year II</i>	<i>Year III</i>	<i>Year IV</i>	<i>Year V</i>
4. Administrative Expenses					
4.1 Operating Costs	\$186,348	\$195,731	\$205,714	\$216,367	\$228,490
4.1.1 Personnel [<i>Adm. Personnel Only</i>]	\$160,750	\$165,573	\$170,540	\$175,656	\$180,926

4. Net Increase (decrease)	(\$62,874)	(\$7,630)	\$25,639	\$22,693	\$10,719
5. Loans & Payments	\$65,000	\$5,000	(\$10,000)	(\$10,000)	(\$10,000)
5.1 Loans	\$65,000	\$5,000	\$0	\$0	\$0
5.2 Payments	\$0	\$0	\$10,000	\$10,000	\$10,000
6. End-of-year Balance	\$7,126	\$4,496	\$15,639	\$12,693	\$719

Biomed Company will have to borrow each year and then to calculate the interest on the borrowed money.

Table 48-14 shows the five-year projection for cash flow. At the beginning of the first year it is assumed that the owners of the company have only \$5,000 left after making the needed capital investment to buy the test and measurement equipment and an initial stock of supplies and other consumables. The cash inflows comprise projected revenue, known as "accounts receivable," for repair services, contracts and consulting work (from Table 48-11), interest received (discussed below), and additional investments that the owners (or other investors) are willing to make each year. Deducted from the inflows are the bad debts discussed above. The cash outflows consist of capital investments, operating expenses, interest, taxes, and dividends (i.e., money paid to the stockholders).

At the end of the first year, Fix-All must raise \$15,000 from its owners (or other investors, collectively called "stockholders") and must borrow \$65,000 from lenders (e.g., banks) to cover its shortfall of \$62,724, to end up with a positive year-end balance of \$7,276. In the second year, the situation is still difficult, because the company still must obtain \$10,000 (i.e., \$5,000 from owners and \$5,000 from lenders) to close the year with a positive balance of \$4,808. The financial outlook for Fix-All improves in the third year, when it is able to pay \$5,000 in dividends to its owners and \$10,000 in principal to its lenders. The balance at the end of this year is projected at \$15,753. In the fourth year, the situation continues to improve. Fix-All is not only able to pay \$10,000 in dividends but it also pays back \$10,000 of principal to its lenders. However, in the fifth year, the situation degenerates. Fix-All is able to close the year with a positive balance of only \$833 after paying \$15,000 in dividends and \$10,000 on loans.

A closer look shows that in the fifth year, the cash outflows are almost as high as the inflows. Several reasons contributed to this bad situation. First, the steady growth of the business created a labor shortage (see Table 48-12), which had to be covered at high cost by hiring temporary workers at \$122 per hour. Second, the growth of the hourly rate charged by Fix-All (4% per year) was simply not fast enough to keep up with the cost of outside services and service contracts. Finally, by adopting the in-house initial rate of \$77 per hour, Fix-All started in a barely profitable condition and just could not earn enough profit to cover the financial costs and dividends. In other words, \$77 per hour would have been fine for an in-house CE department but it was unrealistic for a for-profit enterprise. Had a sixth year been projected, Fix-All would have ended up in deep trouble (i.e., with a negative cash balance).

Table 48-14 clearly shows that the financial planning based on projected income statements (Table 48-10) alone is insufficient if not misleading. In the first two years, if the company were not able to land additional investments from its owners (or new investors) and to borrow money from lenders, it probably would fail. More significantly, even when things seemed to improve in the third and fourth years, Fix-All still would get itself into cash flow trouble starting in the fifth year. This discrepancy is probably easier to visualize by comparing Figures 48-2 and 3. Figure 48-2 shows the after-tax net income from Table 48-10 in the first five years, while Figure 48-3 shows the cash flow in the same period of time. In spite of the ascending trend of the income, the dip in cash flow in the fifth year is a troubling sign. In fact, had the projected numbers for the sixth year been computed, negative end-of-the-year balance would have appeared, showing that the company might become insolvent at that time. This example illustrates well the accounting axiom, "Cash is king."

It should be stressed that, for simplicity's sake, projecting the cash flow monthly and including the delay between invoicing and receipt of cash was not attempted. Although most invoices are issued with 30-day allowances, it is not unusual to receive the money as many as 60 or 90 (sometimes even 120) days later in the current U.S. health care market. This practice makes cash-flow management even more challenging and forces many companies to delay their payment to their vendors, which could retaliate by increasing the price or even refusing to extend credit.

Financial Expenses

With the loans calculated in Table 48-14, the financial expenses projected for the first five years can be computed now. It is worthwhile to call attention to the fact that financial expenses were totally absent from the in-house CE department budget, even though the hospital's finance department is required to consider these costs.

Table 48-15 shows the progression of financial expenses over the first five-year period. The interest that the company receives is simply the interest to be earned on its bank accounts (e.g., a money-market checking account), assuming the rate of 5%. Instead of attempting to calculate exactly the interest to be earned on a daily or monthly basis, it is assumed that the average bank balance is the same throughout the year (obviously an oversimplification, but not material in this case study because of the low value). The values shown in line 5.1.1 are actually those derived earlier in the cash-flow projection. The interest to be paid depends on the net amount of the debt (line 5.2.4) and the interest rate (assumed to be 10%).

Figure 48-2 Projected after-tax net income for a clinical engineering service company in its first five years.

Figure 48-3 Projected cash flow for a clinical engineering service company in its first five years.

Table 48-15 Sample five-year financial expenses projection for a clinical engineering service company

5.2.4 Interest Rate	10%	10%	10%	10%	10%

Balance-Sheet Projection

Now that the two primary financial reports (income statement in Table 48-10 and cash flow in Table 48-14) have been discussed, attention is turned to the third and last primary financial report, the balance sheet. Table 48-16 shows the projected five-year balance sheet for the Fix-All Biomed Company. First, notice that we have a column prior to the first year called "initial." This column records all of the investments made prior to the beginning of operations. All of the labor that went into the organization of the company and miscellaneous expenses such as attorney's and accountant's fees have been lumped together and are called "organization costs." The purpose of this column is to enable the calculation of the return on the money invested in the company.

The balance sheet follows the classical division of assets, liabilities, and equity. In the assets category are included the typical line items of cash, accounts receivable, inventory, property and equipment (also known as "fixed assets"), and organization costs. In the liability category are accounts payable, short-term debts, taxes payable, long-term liabilities, and dividends paid (i.e., to the owners). By definition, equity is the difference between assets and liabilities and therefore it can be positive or negative. Equity is composed of total investment or paid capital (i.e., capital stock at the beginning of the year plus additional stocks issued that year) and retained earnings, which represents money that the company has earned but has not distributed to the owners or shareholders. Because total investment is always positive, retained earnings can be positive or negative, depending on how well the company performs that year.

Prior to the start of operations of Fix-All, the owners invested \$60,840. In the first year, an additional investment of \$15,000 was made, elevating the total invested to \$75,840. Because the liabilities are now higher than the assets, the company ended the year with negative retained earnings of \$126,718. Therefore the value of the company (equity) is negative \$50,878 (= \$126,718 - \$75,840) at the end of the first year (in spite of the fact that a total of \$75,840 was invested).

In the second, third, and fourth years, the situation improved, but the liabilities were still higher than the assets. The retained earnings are negative on all five years, but the equity turns positive in the third year and grows steadily afterwards (Figure. 48-4). However, at the end of the fifth year, the equity is still lower than the total investments made by the owners/stock holders. In other words, if Fix-All were to shut down at the end of the fifth year, its owners would end up losing some of their money after paying all the debt.

At first glance it would seem that the investors would have been better off putting their money into a bank account and enjoying their lives on the beach! This is not necessarily true, however. First, the business has not failed and the owners may still be able to sell the company with some small profit (i.e., for a price that is higher than their accumulated investment). The selling price of a company is not solely related to its current revenue, but a reflection of the future cash earning power. In other words, the trend is more important than the current financial status.

Financial Performance Analysis

Many indices and ratios have been developed by analysts to evaluate the financial performance of companies. Each index (or "ratio") provides some idea about the company's financial status, but there is no universally agreed upon set of indices or ratios that will precisely predict the success of any enterprise. Each industry sector typically has a set of benchmarks that are used by analysts to judge the performance of individual companies.

Some of the indices commonly used for profitability analyses are shown in Table 48-17. The first one, gross income margin, is the ratio between gross income and revenue (both available from Table 48-10, Financial Plan). The next two indices, net income margin and after-tax net income margin, show the net income and after-tax net income as percentages of the revenue, respectively. These three indices show how profitable the company is when compared to others in the same industry. For example, supermarkets typically have low margins (< 5%) but have high turnover of inventory. Stores that sell major home appliances, on the other hand, command much higher margins but have lower sales volumes. The service industry, including CE service companies, often have intermediate margins (5%–10%) and moderate volumes when compared to other industries.

Also shown in Table 48-17 are four indices used to measure how successful or efficient the company is in generating return from the investments made in the form of money (investment), capital (equity), material goods (assets), and total capital employed (assets without considering current accounts receivable and payable). They are, respectively,

- Return on investment (ROI)
- Return on equity (ROE)

3.2 Additional equity [new stocks issued]		\$15,000	\$5,000	\$0	\$0	\$0
3.3 Total investment		\$75,840	\$80,840	\$80,840	\$80,840	\$80,840
3.4 Retained earnings		(\$126,868)	(\$103,917)	(\$50,946)	(\$26,954)	(\$26,222)

Figure 48-4 Projected equity for a clinical engineering service company in its first five years.

- Return on assets (ROA)
- Return on total capital employed (RTCE)

The data needed to calculate these indices are available from Table 48-16, Balance Sheet. As the investments and returns are made and realized at different times, the net present value (NPV) of all investments and returns has been computed so that they can be properly compared at a single time instant (i.e., at the end of each year). A detailed explanation of NPV can be found in most accounting or finance textbooks, and the calculation can be made by using formulas built into spreadsheets or financial calculators. For this example, a general business-loan interest rate (including the inflation rate) of 12% is assumed. Because in the first three years, the accumulated after-tax net incomes are negative, all four indices are not meaningful. However, they become positive in the fourth and fifth years, and both ROI and ROE are above expectations when compared to other businesses. This is not surprising, as service companies typically require few assets and investments in order to start and operate. The expertise and tal-

ent of their owners and employees are their most important asset, but they are not quantified until the company is sold (i.e., they are included in the good will). The reason that ROA seems to be below expectations is that it includes a large amount of accounts receivable (see Table 48-16). To eliminate the influence of accounts receivable, a more appropriate parameter, the total capital employed (TCE), has been created. TCE is defined as the difference between assets and current liabilities, which is shown calculated in Table 48-18 by subtracting the long-term liabilities from all liabilities. In other words, TCE is essentially all of the assets without accounts receivable and accounts payable. Again, TCE for Fix-All is above expectations because this is a service company.

Table 48-18 shows two indices, current and quick ratios, which are designed to measure the liquidity of the enterprise (how capable is the company to meet its short-term financial obligations). The current ratio is calculated by dividing the values of all current assets (i.e., excluding fixed assets) by all current liabilities (i.e., excluding long-term debts), whereas the quick ratio also excludes the inventory from the assets (because it is not certain that the existing inventory can be sold at the value estimated by the company). The quick ratio is also known as the "acid test" because it measures the company's capability to meet its immediate obligations, whereas the current ratio provides an estimate of this capability for the near term (i.e., 3–6 months).

Break-Even Analysis

Although not always required by lenders and venture capital companies, the break-even analysis is a useful tool for the company managers and owners. This analysis is used to determine the level of sales (i.e., break-even sales [BES]) that must be attained in order for the company to meet cash obligations, such as operating expenses and debt payments. Table 48-19 shows how this analysis is made.

BES is defined by the following equation:

$$\text{break-even sales (BES)} = \text{fixed costs}/(1 - \text{variable costs}/\text{revenue})$$

To determine BES it is necessary to segregate all costs into fixed and variable categories. In the fixed-costs category are the administrative expenses and the financial expenses. In the variable costs are the cost of sales. All of these values can be obtained from Table 48-10 (Financial Plan). Comparing the BES thus calculated with the projected revenue (also from Table 48-10), BES is higher than the projected revenue in the first two years but then becomes lower, starting in the third year. This calculation confirms the fact that the net income in the first two years is negative.

Besides this obvious conclusion, the BES equation helps us to visualize two statements made previously:

Balance	1.3 Inventory	\$0	\$0	\$0	\$0	\$0	
	Current Assets -Inventory	\$404,266	\$476,921	\$553,491	\$653,717	\$764,883	
	Quick Ratio**Acid Test**	94%	101%	109%	109%	106%	>30%

- To increase profit (or value, in the case of an in-house CE department), one should try to reduce the fixed costs (or overhead) as much as possible, as it reduces the amount of sales needed to break even.
- It is acceptable to increase variable costs, as long as they help to increase revenue by at least the same percentage. Better yet would be to reduce variable costs as a percentage of the revenue.

Discussion

From the foregoing analysis it is clear that the transition from an in-house CE department to a for-profit company is quite challenging in financial terms. Although initially the profit margin seems to be adequate, the cash-flow projection shows that the Fix-All Biomed Company could falter because of cash-flow troubles. One of the problems detected in the fifth year is the lack of internal labor to cover all of the service and contract needs. One possible solution that was not explored here would be the hiring of an additional biomedical technician. Because an employee's rate is less costly than that of temporary help (or an overtime rate), this option could improve the bottom line. If, however, a more global solution were desired, the possibility of raising the hourly rate from \$77 to, for example, \$85 should be considered. With a spreadsheet one can see that this small (10.4%) increase will improve the whole financial picture significantly. Obviously there are other possible solutions. The purpose of financial planning is exactly to allow the managers to visualize potential problems and to simulate different scenarios and alternatives before making a decision.

As stated before, numerous assumptions and forecast have to be made in the projection of income, cash flow, and balance. Consequently, the financial plan can be only as good as the assumptions and forecasts made. As it is impossible to foresee all of the possibilities and challenges, management will need to make adjustments and corrections as the company evolves. This does not mean that the initial plan is useless or that it would not be worthwhile to go through the trouble of performing financial planning. The value of financial planning is actually not in the plan achieved but in the planning process itself (thus the saying "Having a plan is nothing, planning is everything"). This is because during the planning process one is forced to think carefully about every step of the business process before taking it. This exercise helps managers to identify the critical steps of the process and the assumptions that might have to be revised when the circumstances change.

Although the financial-performance analysis presented above seems to provide a simple and powerful set of tools to analyze and compare companies. These tools (ratios and indices) should be used with great care. In reality, these tools produce better questions than answers, i.e., they will suggest when and where to look deeper for signs of trouble

or poor performance. If properly used, financial-performance analysis can provide information and insights for at least three critical tasks. First, it will assist in the allocation of capital in order to maximize return and to minimize risk. Second, it will identify a company's financial and operating strengths and weaknesses (two important components of a financial strengths, weaknesses, opportunities, and threats [SWOT] analysis). Finally, it will help to evaluate managerial performance in order to determine appropriate compensation and promotions. Typically, this kind of analysis is performed by comparing companies within the same industry (cross-sectional analysis). Occasionally, the analysis also can be made across various industries to determine the overall performance of each industrial segment. Sometimes, analysis can be executed to identify trends and exceptions over time (time-series analysis) and to compare financial position and results from period to period.

Conclusions

The two case studies presented above illustrate ways in which CE managers can manage the finances of their departments or companies, especially ways to control and reduce the costs without affecting the quality and thus to remain competitive. Certainly there are many omissions and inaccuracies in these case studies, but they provide enough details to demonstrate the basic principles of financial management for an in-house CE department and for an independent service company. Starting from these case studies, readers should be able to build more complete and accurate financial models of their own operations in order to assist them in successfully growing their department or enterprise.

Although the in-house CE department seems to be more cost-effective than the for-profit company, one should not conclude that this is always the case. The reality may be quite different. Often, for-profit companies are less generous than health care organizations in terms of compensation and benefits. The former are often subject to contracts negotiated by labor unions. Service companies also tend to have a much higher ratio of BMETs to clinical engineers than do hospitals, especially when they sustain multiple health care organizations, effectively reducing the overhead costs (an advantage provided by economies of scale). Finally, multivendor service companies are typically less involved in activities that are not strictly maintenance and repair (e.g., user training, incident investigation, and pre-acquisition assessment), thereby improving their productivity when compared to in-house CE departments. After all, for-profit companies would not remain in business if they could not be profitable.

A cost benchmark that has been used and preferred by some CE managers is the total cost of services as a percentage of the equipment inventory (Cohen et al., 1995; Cohen, 1998). In the case studies presented here, the hourly rate was used as the main cost benchmark. It is indisputable that the hourly rate depends significantly on the sophistication of the equipment covered. (Typically, the imaging technicians command higher pay than those who service biomed equipment.) However, a smart CE manager utilizes a mixture of internal capabilities and outside service contracts to satisfy the need of his employer, no matter whether it is a health care organization or a service company. The goal of every CE manager should be to maximize the service impact while reducing costs rather than building a CE empire. Therefore if the CE department or company were properly managed, the hourly rate benchmark would be more accurate and easier to compute than the percentage-of-inventory benchmark, as the latter requires constant revision of current equipment replacement costs. The original acquisition cost should not be used because it does not consider inflation and accumulated interest, or possible deflation of equipment prices.

Another benchmark often used by CE managers is cost avoidance or money saved (Cohen et al., 1995; Gordon, 1995). This benchmark is calculated by comparing the costs of internal labor versus outside services and/or the reduction of breakdowns (down time) because of preventive maintenance. Unfortunately, the money saved is not tangible (it is known as "soft money") and thus it has little credibility with administrators and financial analysts.

Irrespective of the benchmark(s) used, it is clear that CE managers must know how to manage their finances at least as well as—and probably better than—they know how to service the equipment. The case studies shown here demonstrate that the mathematics needed is not that advanced and the calculations can be accomplished with a stan-

Table 48-19 Sample break-even analysis for a clinical engineering service company

	Excess (Shortfall)	(\$98,665)	(\$24,579)	\$111,430	\$128,881	\$117,353

spreadsheet program or basic business-accounting software. Accordingly, one should start immediately to collect the numbers and to enter them into the computer to calculate current hourly labor cost unless, of course, one plans to retire in the next six months or intends to visit the unemployment office to fraternize with the in-house CE managers who lost their jobs because they were unable to justify their costs. Worse yet would be if one stood in the bankruptcy court queue with the CEOs of independent or shared-services companies who “lost their shirts” through improper management of cash flow.

Cost-Effectiveness and Productivity

Larry Fennigkoh

Associate Professor, Electrical Engineering and Computer Science Department, Milwaukee School of Engineering, Milwaukee, WI

Throughout most of clinical engineering, the maintenance, support, and management of health care technology occupy most of the profession's time, talent, and thought. Increasingly, and somewhat ironically, these functions also are receiving considerable financial scrutiny by hospital administrators and quality-improvement consultants. The irony is that some of the very services that exist in order to save money often are being eliminated, supposedly to save money. Calls for increased productivity, accountability and staff and budget reductions abound. Clinical engineering, like many other health care service functions, continues to struggle with the challenge of answering such calls. Despite the efforts and early pioneering work of many of the profession's founding fathers (Shaffer, 1974; Ridgeway, 1980; Johnston, 1983; Furst, 1986; Bauld, 1987), a consensus as to the best way to characterize and monitor clinical engineering's cost-effectiveness and productivity has yet to evolve. As a result, in part, many hospital-based clinical engineering departments have been caught somewhat off-guard when the challenges to justify their existence are made.

While this chapter does not attempt to summarize the work of the past 30 years, it does offer (1) a brief review of the underlying difficulties associated with the development and use of performance measures (acquiring an appreciation and awareness of these difficulties is crucial before implementing any form of productivity-measurement program), (2) a summary of some reasonably well-accepted definitions and performance metrics, and (3) some suggestions for improving clinical engineering cost-effectiveness and productivity through a more proactive approach to department management.

Why Measure Cost-Effectiveness and Productivity?

The implicit benefits of being able to measure cost-effectiveness and productivity comes from an underlying—and perhaps somewhat flawed—assumption that service activities in general, and clinical engineering functions in particular, may be managed like closed-loop feedback-control systems. Here, and as illustrated in Figure 49-1, this assumption maintains that if and only if outputs from these functions can be appropriately measured, then outputs can be controlled and improved. While this notion is particularly true in the manufacturing sector and works extremely well at optimizing and maintaining product quality, it has not transferred well to clinical engineering, where the outputs tend to be services, not manufactured goods. Admittedly, this author was also an early and strong proponent of this classical method (Fennigkoh, 1986, 1987).

Specifically, the fundamental differences between services and products make use of this model in a service environment so difficult. As characterized by Dunn (1985) and Fennigkoh (1987), service functions differ from manufactured products in the following, unique ways:

- **Intangibility:** “Services are intangible and can seldom be tried out, inspected, or tested in advance.” This vagueness also increases as the services become more sophisticated and technical. Here the buyer's perception of what is being “bought” could be entirely different from what is actually being “sold”.
- **Perishability:** “Services are also perishable, meaning that they cannot be inventoried for later sale. An unsold service is lost forever.” In essence, time is the product. (Williams, 1986).
- **Nonstandardization:** While service-delivery mechanisms can be standardized, e.g., the manner in which orders are taken, processed, the manner in which the services are provided depends largely on the highly variable and complex behavior of the human delivering the service.
- **Inseparability and buyer involvement:** “Services are generally inseparable from the source that provides them or from the buyer who benefits from them.” This inseparability places a considerable time constraint on the classical feedback-control model. The service already has been delivered before any feedback is obtained (i.e., the service function is effectively operating in an open-loop, rather than closed-loop, mode).

These unique differences between services and products become even more profound and problematic when combined with the simplified closed-loop model of clinical engineering service delivery (Figure 49-1). While the feedback model appropriately acknowledges the need for management to monitor CE department function and performance and to use this information to further improve such performance, it also presumes that the service outputs are being measured appropriately, consistently, and accurately. Errors or flaws in obtaining these measures result in management responding to, and attempting to control, the wrong things. Skepticism, disagreement, and mistrust result.

Problems with the Measurement of Service Productivity

The following concepts embody the fundamental difficulties associated with the measurement of service cost-effectiveness and productivity:

1. Any closed-loop service model is primarily reactive in nature. That is, only after the service has been rendered and its performance measures presumably collected and analyzed, can the service be improved. In many institutions, this may be months after the service has been delivered. Granted, the availability of meaningful measures of service output can be extremely useful in monitoring trends and in developing

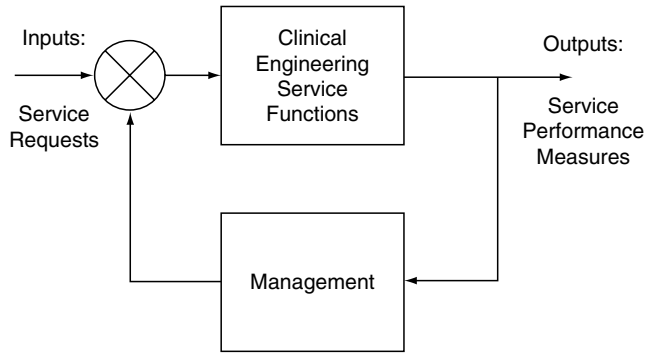

Figure 49-1 Classic closed-loop model of clinical engineering service delivery.

projections. However, the inherently reactive nature of this model places an often unintended emphasis on counting (e.g., productivity ratios, hours of service, number of repairs, and PMs) rather than on serving. This distinction is precisely what Peter Drucker (1993) noted in an article in the *Wall Street Journal* in which he encouraged the service industry to develop measures that “give us effective business control” rather than those that are means for simply counting things.

2. The “good” or “bad” judgments that tend to accompany such counting-based programs often only encourage the service staff to make the numbers “look better” rather than to deliver better services.
3. Perhaps the most insidious of the productivity-measurement problems is related to the reliability and validity of such measures. These terms have very specific and crucial meanings within the statistical and scientific community. Weaknesses in either of these characteristics weaken the use and value of the measure. Most of the problems experienced with the development and use of clinical engineering performance measures can be traced to weaknesses in their reliability and validity. Specifically, the validity of any given measure is defined as “the extent to which an instrument measures what it is intended to measure” (Portney, 2000). Validity also implies that a measurement is relatively free from error; i.e., that it is also reliable. In this context, reliability is the extent to which a measurement is consistent and free from error. The differences and relationship between these two concepts are illustrated Figure 49-2. Here, the target offers a useful analogy of what clinical engineering should be “shooting for” in its continuing development of appropriate service measures.

Many of the performance measures discussed below suffer from weaknesses in both their validity and reliability. Consider, for example, the classic measure of productivity, which often is expressed as a percentage of the ratio of recorded labor hours to paid hours. As such, it is simply a measure of time that was recorded, not necessarily how effectively the service staff did their jobs. In this regard, a productivity ratio would not be a valid indicator of service effectiveness. Similarly, if the service staff were not consistent and honest in their recording of labor hours, such a measure also would not be reliable. Consequently, managers who now attempt to “improve” service performance based on this single, unreliable, and invalid measure of “productivity” often create more problems (and less productivity).

The development of valid performance measures, particularly for service-based functions, is especially problematic because service quality is largely subjective in nature. It is, quite literally, in the perceptual eyes of the customer. Consider the many factors that influence a customer’s level of satisfaction with any service function (Figure 49-3). Now try to determine a way to measure these factors. The difficulty in doing so (and, often, the inability to do so) also represents issues of measurement validity. Any measure that does not truly measure what it is intended to measure is not a valid measure.

In the typical health care environment, clinical engineering service quality and hence its perceived level of cost-effectiveness are consistently evaluated by the composite mix of all of these factors. The intrinsic difficulty in trying measure these service attributes is precisely why the proactive approach to clinical engineering productivity is offered later in this chapter.

Even if the clinical engineering profession were to derive some valid measures of cost-effectiveness, the second crucial criterion for this measure is its reliability. Again, reliability refers to the relative freedom from error and the consistency of the measure. Because virtually all of the published metrics rely on the accurate and consistent reporting of service labor hours, quantities, or costs, all of these are subject to considerable variability in their capture and recording (i.e., they can lack reliability). Reliable time recording is especially problematic if it is perceived that these records will be used in subsequent employee performance reviews and productivity reports. Here, the tendency is for the service staff simply to record more time than they actually have expended, to make

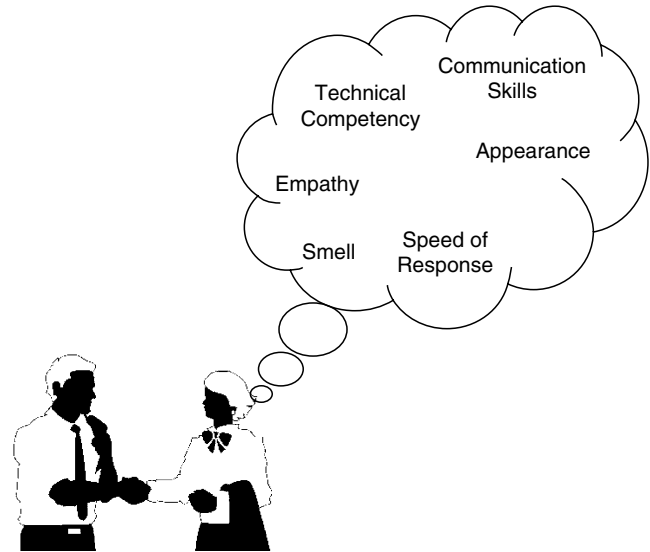

Figure 49-3 Perceptual factors influencing customer satisfaction with clinical engineering service delivery.

their numbers “look good”. As a graph of any inverse function, e.g., $y=1/x$, would reveal, any performance measures involving labor hours in the denominator of a ratio (e.g., service costs/hour, repairs/hour, and PM inspections/hour) are profoundly sensitive to variations or error in these labor-hour measures. Here, relatively small inconsistencies in reported time can have profound effects on the derived measure. Unless management has some assurance that the reported labor hours are reasonably accurate, these labor-based hours should be used judiciously.

Despite these problems of measurement validity and reliability, a variety of derived measures and techniques have been reported. While care needs to be exercised in the interpretation and use of these measures, they may offer clinical engineering managers some insight as to the way their departments are functioning. In this regard, they may be particularly useful in revealing performance trends—e.g., growth, stability, or decline—and thus their use is would be encouraged. All such measures, however, remain reactive, or retrospective, in that they can be calculated and evaluated only after clinical engineering services have been rendered.

Before reviewing such measures, some basic definitions upon which these measures are based are reviewed.

Definitions

Despite some institutional variations in productivity nomenclature and definitions, a few reasonably standardized terms and concepts should be established before any measures are developed and implemented.

Effectiveness: “The capability of producing the desired results, i.e., doing the right things at the right times” (Bauld, 1987). Within the service industry in general and health care in particular, effectiveness is a subjective assessment made by the customer, often based on perceived quality and speed of delivery.

Efficiency or Productivity: “The ratio of output per unit of input or the ratio of production to the capital and resources invested” (Bauld, 1987). More specifically, productivity has been defined as:

$$\text{Productivity (\%)} = [(\text{Chargeable hours})/(\text{Total worked hours})]100$$

Lodge (1991) makes a further distinction between productivity and efficiency and with measures of the latter for any given task being expressed as below:

$$\text{Efficiency (\%)} = [(\text{actual job hours})/(\text{industry standard hours})]100$$

Other derived measures that have been particularly useful for trending service functions on a monthly basis are summarized in Table 49-1 (adapted from Fennigkoh, 1986).

One of the most informative and intuitively meaningful measures, however, remains the effective hourly labor rate or service cost per hour. Simply, how much does it actually cost the institution to support a clinical engineering service function? As originally reported

Figure 49-2 Representative targets illustrating the differences between reliability and validity. (A) Measures are highly reliable, but not valid. (B) Measures are neither valid nor reliable. (C) Reliability has improved but is still low. (D) Measures are both valid and reliable. (Adapted from Portney and Watkins, 2000).

Table 49-1 Derived measures for trending service functions

Performance metric	Clinical engineering service functions		
	Unscheduled service requests	Scheduled maintenance inspections	Failure-mode assessments
Work volume-based	Volume/month Volume/device class Volume/technician Volume/FTE % completed (1 day)	% completed PMs/month	Volume or % of: No problem Operator error
Labor (hours)-based	Hours/request Hours/device Hours/technician % productive	Hours/PM % PM labor	Labor hours or % due to: No problem Operator error
Cost-based	Costs/request Cost/device % acquisition cost Average labor costs	Costs/PM Costs/PM/device	

by Johnston (1983), measures of hourly labor costs can be determined with the following expression:

$$\text{Cost per hour} = (\text{total department budget}) / (\text{total productive hours})$$

In order for such a measure to be valid, department costs should reflect all costs that the department incurs for the institution. Conventionally these are referred to as “variable” and “fixed” costs. These would include, at a minimum, salaries, benefits, travel, parts and service supplies (even estimates of parts-inventory carrying costs should be included here), telephone, depreciation, and fixed-cost estimates associated with the space that the department occupies. In essence, what would be the department’s total costs if it were forced to become totally self-sufficient?

In the denominator of the cost-per-hour equation should be a measure of the total productive, or billable, hours that are available within the department. This includes adjustments for vacation, sick time, training days, holidays, and some reasonable estimate of productivity, e.g., 70%–75%. Effectively, this is a measure of time during which the service staff is actually doing something that it legitimately could charge a paying customer. As such, and as mentioned earlier, this measure of labor cost per hour is extremely sensitive to variations (or errors) within the denominator of this equation. Given that,

$$\text{Total productive hours} = (\text{total paid hours} - \text{vacation productivity})$$

the complete equation becomes:

$$\text{Costs per hour} = \frac{[(\text{variable costs} - \text{parts costs}) + (\text{fixed costs}) + (\text{administrative costs})]}{[(\text{No. of FTE's}) \times (\text{total productive hours})]}$$

Again, with the productivity factor in the denominator of this equation, it should be apparent why productivity has such an impact on the effective costs to the organization.

A Proactive Approach to Clinical Engineering Productivity

Rather than view clinical engineering functions as a set of traditional, closed-loop systems and processes, a somewhat open-loop—and, admittedly, somewhat abstract—view of the service function is offered. Such a view, however, is from the perspective of the customer and not that of clinical engineering department management. As illustrated in Figure 49-4, this view is of what the customers, the users of health care technology, consciously or unconsciously expect from providers of clinical engineering support. These expectations include the following:

1. Speed or a reasonably quick response to their service requests
2. Quality work, which, in the eye of the beholder, includes a pleasant attitude and appearance, and empathy, as well as work that correctly solves the original problem(s)
3. Reasonably low cost or transparent cost

As shown in Figure 49-4, customers are the most satisfied when the clinical engineering department consistently operates in the zone of high-quality, quick response time, and low cost. In doing so, the department tends to become increasingly more invisible to the end-customer. In many ways, such a level of invisibility becomes the epitome of customer service and cost-effectiveness. Departments that achieve such levels of invisibility can

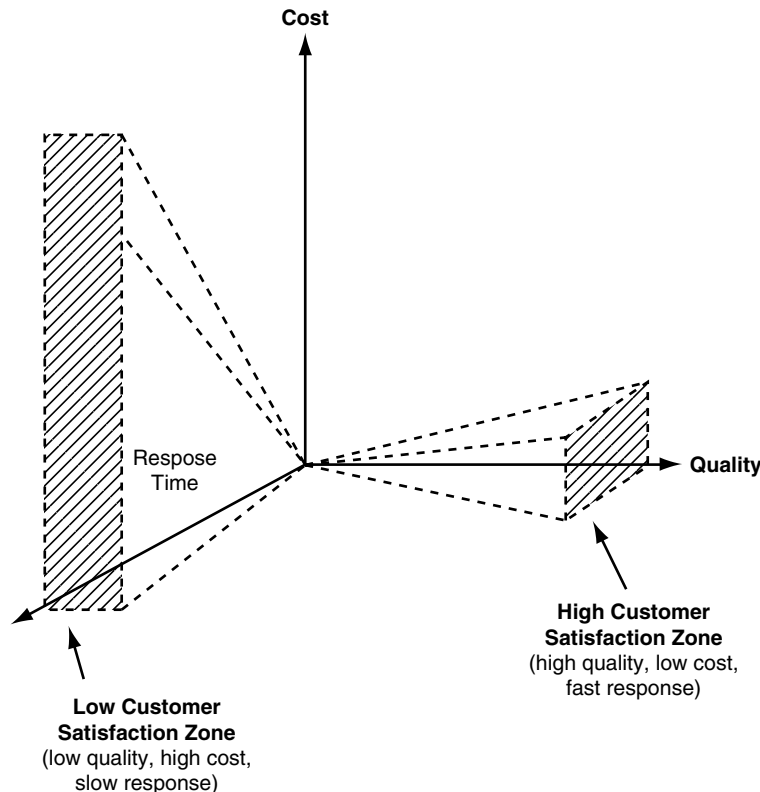

Figure 49-4 Factors influencing customer satisfaction with clinical engineering services.

only do so by becoming cost-effective. Cost-effectiveness and productivity in clinical engineering then become a mere by-products of a program that consistently satisfies its customers, and not things that must be measured or exhorted into it.

Clinical Engineering Program Indicators

Dennis Autio

Sr. Clinical Engineer, Department of Veterans Affairs
 Portland VA Medical Center
 Portland, OR

The role of the clinical engineering department evolved from a task-oriented repair shop to a complex business incorporating a full range of clinical engineering services (Bronzino, 1992). This change has been rapid over the past 15 years, often motivated by economic factors affecting health care delivery. To continue to exist during these changing times, clinical engineering departments had to demonstrate performance (Keil, 2000) and value-added services to their parent organization if they were to be successful in competing for limited financial resources. Difficult decisions were made. Some programs were eliminated, and the previous services were contracted out to other organizations. Other programs were significantly reduced in attempts to reduce costs by reducing services. Successful clinical engineering programs embraced this change, often struggling initially to develop tools and practices to help them to create a new, business-focused, bottom-line-oriented support organization.

As new business practices were integrated into existing clinical engineering programs, it became important to develop objective, reliable indicators to document performance and to measure improvements in the services provided (Fennigkoh, 1986; Hertz, 1990; JCAHO, 1990; Audio and Morris, 1995; Keil, 1998a Audio and Morris, 2000;). This became a powerful tool when departments could demonstrate high-quality service at a competitive cost (Stiefel, 1991). Clinical engineering programs now could use this tool to strategically plan for the future using high-performance work teams that used continuous quality improvement methodologies (JCAHO, 1994). This empowering process took time to understand and to identify the ways in which it could be implemented in the workplace. With training and time, the clinical engineering staff was able to implement unique solutions for its facilities. Some of these solutions could be integrated into programs at other facilities. Throughout this process, one common factor was the use of indicators to monitor program performance. When coupled with threshold measurements and trend/pattern-analysis techniques, clinical engineering departments could better compete with the marketplace to provide timely and cost-effective proactive services.

Developing a clinical engineering program that uses indicators to manage performance requires several important planning steps. The services provided by the program must be defined. The process to document these services and to acquire data must be standardized into a usable database. The department's philosophy must be understood by all staff members and aligned with those of the organization. Staff must understand the process to develop program indicators with appropriate thresholds and how use objective data to measure the department performance. These indicators also can be used to help assess problems and to identify opportunities for quality improvement (Sherwood, 1991; AAMI, 1993a; Keil, 1998b; Al-Fadel and Crumley, 2000). When compared with similar indicators used at other facilities, they can be used to identify best practices for integration into your program.

Clinical Engineering Program Services

Clinical engineering programs have evolved from equipment maintenance (e.g., repairs, periodic inspections, and modifications), to include equipment management (e.g., installation, incoming inspections and acceptance testing, hazard notification, user-error iden-

tification, incident investigation, contract management, training, and database management) and technology management (e.g., assessment of new technology, pre-purchase equipment evaluations, and specification development). (See Chapter 30.) Not all clinical engineering departments provide the same type or level of services. Therefore it is important to define the clinical engineering services that are specific to a particular department. A broad range of clinical engineering services is listed below:

- **Corrective Maintenance:** Any services that involve medical equipment repair would be included in this category. Specific services include repairs performed by in-house personnel or vendors, repairs completed during the warranty period, repairs completed as a result of a hazard notification, repairs resulting from user error, and repairs performed under a service contract (see Chapter 37).
- **Inspections and Periodic Maintenance (IPM):** This includes various types of services, including electrical safety inspections, operations checks, scheduled IPMs performed by staff or vendors, and unscheduled IPMs performed by staff or vendors. Some of the IPM services may pass inspection, some may fail the inspection, and some inspections may be canceled.
- **Education:** Various educational services are provided by clinical engineering departments including training users on procedures and proper equipment use. In addition, clinical engineering staff training must be provided and documented (see Chapter 51).
- **Equipment Management:** Various services are specific with managing the equipment supported including developing and managing the database, pre-purchase equipment evaluations, specification development, incoming inspections, acceptance testing, and removing equipment from service (AAMI, 1993b).
- **Contract Management:** Contracts with various vendors that are managed by your clinical engineering department may be in effect. Services here include developing the specific contract specifications, coordinating services with the vendor, reviewing vendor services provided, and documenting services into your equipment management program (Hyman and Cram, 1999).
- **Risk Management:** This category includes assessing equipment for inclusion into the equipment management program, identification of user errors, hazard-notification review, incident investigation, Safe Medical Device Act-Medical Device Tracking, and Safe Medical Device Act-Device Incident Reporting (David and Judd, 1993; Wang and Levenson, 2000).
- **Technology Assessment:** Depending on the focus of the department, different clinical engineering services can be provided including problem investigation, equipment modification, instrumentation design, planning for implementation of new technology, and planning for the replacement of existing technology (see Chapter 32).

Clinical Engineering Program Database

Once one is able to define the clinical engineering services provided by one's department, the next step is to identify the way to capture the data associated with providing these

services. Various equipment management programs that provide this service are available commercially (AAMI, 1994; Selsky et al., 1991). Data entry and data retrieval are important issues to assess with any of these programs because one will want to be able to compile the data quickly and present them in a manner that allows for quick analysis. (See Chapter 36.)

Specific equipment data are needed to uniquely define each equipment item included in the equipment management program. General equipment information includes manufacturer, model number, and serial number. Equipment management information includes facilities asset management tracking number, department using the equipment, equipment category type, and risk assessment. Additional helpful equipment information includes acquisition date, acquisition value, warranty period, and warranty expiration date. One should capture this basic information for all equipment that is supported in this program.

There is a core set of data that are helpful in managing the performance of a program. In addition to providing an equipment history for review, these data allow the categorization of the services provided, documentation of the amount of time spent performing these services, identification of the timeliness of service, and definition of the cost for this service. At a minimum, these data sets should enable the following data to be captured:

- **Work Categories:** Definition of the specific work tasks that categorize the services provided by the department is necessary. These tasks may include repair, IPM, incoming inspection, acceptance testing, equipment design/modification, hazard notification, user error, training, evaluation, and specification development. It may be important to further define some of these services into additional categories. For example, one may want to break down IPMs into "IPM-Complete," "IPM-Uncompleted," or "IPM-Failed." This allows easy monitoring of the IPM services provided.
- **Equipment Identification:** Identify the specific equipment in which this service was provided. Some services will not be associated with an equipment item, such as equipment evaluations, specification development, or review of hazard notifications.
- **In-house Support:** This includes both the labor cost and the number of hours spent performing the service. Labor cost should reflect salary, benefits, space, utilities, productivity, and administrative overhead. Hours should include travel time, research time, coordination time, and the actual time required to provide the service.
- **Vendor Support:** This information is included on the service report. It includes the hours spent providing the service, including travel hours and repair hours. The costs may include a travel rate, repair rate, and possible *per diem*.
- **Contract Vendor Support:** The actual hours and cost incurred when equipment is supported by a vendor under a service contract must be identified. While important to include in the equipment history, this information often is not captured. In addition to the total cost of the contract, one should capture the individual vendor's hours spent supporting the equipment and the appropriate labor cost.
- **Parts:** Identify the description of the parts used and the cost of each part. The actual cost of a part is not simply the purchase price but may include the costs of acquiring and storing it. The descriptions and costs for the parts provided by the vendor and the staff should be included in the equipment history.
- **User Identification:** Identify the person who is bringing the problem to your attention, including their name, phone number, department, and location.
- **Date/Time Indicators:** Identify the date and time when the problem was first identified, when it was responded to, and when it was resolved.
- **Problem Description:** Define the nature of the problem encountered.
- **Solution Description:** Describe the solution identified for solving the problem.

In addition to capturing the above data, this program also should allow you to schedule and document IPMs and user training. Merely defining the services provided and the database is not enough. The clinical engineering staff must be trained on the department's philosophy, policies, and procedures. This ongoing process must be constantly reviewed and updated as a program evolves. Each staff member must be able to define the specific clinical engineering services provided and the way that this information is captured in the database. This staff understanding of practice and procedures will provide standardized data for future analysis.

Clinical Engineering Program Management

After determining the services provided and defining the database, the management practices must be assessed. Successful clinical engineering departments define their mission, vision, values, and goals, making sure that they are aligned with those of the parent organization. A mission statement describes the services that the department provides to the organization. The vision statement describes the direction in which the department is going. A value statement and definition of excellence help to define what is important to the department. Goals then can be developed, integrating the mission, vision, and values.

Strategic planning is an important process for any successful clinical engineering department. It allows assessing the current position, identifying immediate problems to be addressed, and defining future directions. This is often not an easy process. It requires balancing available resources with the needs and priorities of the organization. Effective planning requires access to data that describe the department's performance and the way its resources are being utilized. Indicators are measurement tools that are useful in quantifying these services. They can be used to identify opportunities for quality improvement and to compare services with those that are provided by other organizations to identify opportunities for improvement. Each of these techniques allows the development of strategic plans, including department goals to improve performance.

Although a department may define generic goals, it is important to define specific goals to focus their attention and efforts. These goals will change periodically, often being driven by other issues that affect the organization. It is important that staff members understand the specifics of how these goals were developed and how they can meet them. In order to determine whether progress is being made to meeting goals, an indicator and

measurement tool to monitor performance is required. Effective indicators can be used to monitor department performance and quality improvement opportunities and to allow comparison with other organizations.

Monitoring Department Performance: Indicators can be used to monitor the services provided by staff members, teams, and the department. Indicators should be accurate and objective. They can range from simple tallies (e.g., the number of jobs completed), totals (e.g., the number of hours spent doing specific tasks), or percentages (e.g., the percentage of available time spent performing specific tasks). There is a tight linkage among individual, team, and department performance. As indicator data are made available, they can become a tool to prioritize and schedule pending activities, keeping everyone focused on what is important.

Quality Improvement Opportunities: While managing the department, problems will be defined. These often are identified when program-indicator thresholds are not met or when trends and patterns are identified. At this time, the department can implement a quality improvement process to define the problem, assess the options, develop a solution, and implement an action plan to correct the problem. Program indicators are then used to monitor the effectiveness of the solution.

External Comparison: On occasion, the opportunity may arise to compare program indicators with those that are used in other facilities. These benchmarking opportunities allow the incorporation of best practices of other organizations. Care must be taken in carefully defining the program indicators used for this comparison. If one is able to define comparable program indicators among different departments, the resulting gap analysis (i.e., differences in program indicator values obtained among facilities) can identify opportunities for improvement.

Clinical Engineering Program Indicators

Once services have been defined, the database developed, and the management practices put into effect, developing a process to review and assess program performance should begin. It is important to recognize the importance of valid data. By identifying a minimum data set required to define the services provided, one can reduce the variability of data acquired by different staff members. After appropriate training, every staff member should be able to effectively identify the clinical engineering services provided and to document it properly. Without complete data the analysis becomes problematic. Over time, the information in the database becomes important to help assess department and staff performance and in relation to the services provided. This information increases in importance as problems are resolved. In order to use these data effectively, a program that utilizes indicators to monitor clinical engineering services performance must be designed and implemented.

An indicator is a reliable, valid, quantitative process or outcome measurement that relates to performance quality. This objective measurement is reliable if different people can derive the identical measurement from the same data set. It is valid if the information obtained from analysis presents an opportunity for quality improvement. Keep in mind that an indicator can be positive (e.g., the number of IPMs completed in a month) or negative (e.g., the number of IPMs not completed in a month). In either case, it provides information for further analysis. An indicator can assess different aspects of performance, including timeliness, efficiency, productivity, efficacy, safety, or customer satisfaction. With time, the reliability and validity of program indicators should evolve to the highest level possible.

An indicator can be used to measure and monitor different steps of a process. It can be used to assess the outcome of a specific process, such as the number of anesthesia-machine IPMs completed in a year. It also can be used to assess specific steps or results obtained during a process. One example would be the number of infusion pump repairs in a year that took over two weeks to complete because parts were not available.

Indicators can be fall into one of two categories. A "sentinel event" indicator documents an undesirable event, often relating to safety issues, and does not occur often. One example could be an equipment failure that results in patient injury. An "aggregate data" indicator documents performance based on many events. One type is a "continuous variable" indicator, where the value is measured over a continuous scale. One example of this type of program indicator would be IPMs scheduled per year. The other type is a "rate-based variable" indicator that is represented as a proportion or ratio. As a proportion, the numerator is a subset of the denominator, such as the number of IPMs completed per total number scheduled. As a ratio, the numerator and denominator measure different parameters, such as the number of repairs per 100 beds.

There are many program indicators that can be used to monitor clinical engineering performance. It is easy to fall into the trap of trying to measure everything. Identifying appropriate, selective indicators requires careful planning and assessment. The indicator is only one step in the performance management process. The indicator should evolve with time as an understanding of the processes is gained.

Managing Clinical Engineering Program Performance Using Indicators

The design of a program that uses program indicators to manage clinical engineering performance requires careful attention to detail and must be integrated with the overall program goals. The flowchart of this process is shown in Figure 50-1 and is explained below.

Identify Indicator and the Threshold: A specific part of the program to monitor performance should be selected carefully. This selection process may result from a professional assessment of the program, user-satisfaction surveys (Keil, 1999), choices made staff members, suggestions from administration, and identification of a quality improvement opportunity or benchmarking with another organization (Coopers and Lybrand, 1994). One should identify the specific part of the program being monitored, describe

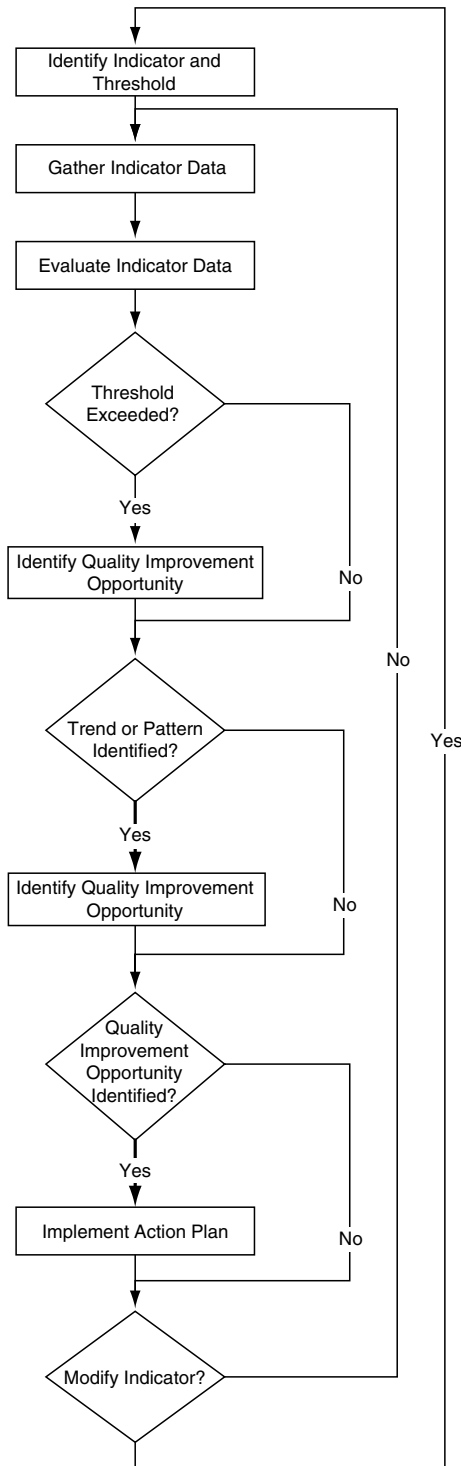

Figure 50-1 Indicator management process.

any specific terminology used, and define the specific indicator to be used to monitor performance. Once the indicator is identified, an associated threshold must be defined. A threshold is a specific data point that, once reached, identifies the need for further review to analyze the data and to assess why the threshold was reached or exceeded. A threshold should be considered a goal for the department, which can change with time and understanding of the processes. If a threshold is not met, then a possible quality-improvement opportunity exists to improve performance. One example of a threshold could be 100% of the scheduled IPMs for equipment with risk score greater than 12 is completed within four weeks. The threshold (100%) is set for the indicator (completed IPM's) monitoring a population of equipment (with risk score greater than 12) for a period of time (four weeks).

Gather Indicator Data: Once an indicator is defined, the various data sources and data elements must be defined. A standardized database assists greatly in this process because the staff continues to use the same process as before to collect data. Timeliness of data collection is important. Staff should be encouraged to document these activities in a timely manner to allow for rapid data collection.

Evaluate Indicator Data: As data are gathered it becomes important to be able to quickly compile the relevant data and present them in a manner that is easy to interpret. Using thresholds often allows the use of a single number to define performance. This can be easily reported in tabular or graphical format.

Determine Threshold: One first should determine whether the threshold of the indicator data was met. If so, then one should proceed to the next step of looking for trends and patterns. If the threshold was not met, then a quality improvement opportunity possibly exists and must be explored. This requires a more detailed analysis of the indicator data. Sometimes a department decides to change the threshold measurement based on historical data and a desire to better document the performance provided by a department.

Identify Trends or Patterns: A trend is the general direction that an indicator takes over a period of time. It can be positive, negative, or neutral. A pattern is a distribution of indicator measurements. A pattern analysis often takes place after a threshold is crossed or a trend is identified. Additional information is often required in order to answer questions that may arise, to identify trends or patterns. Again, staff proactive participation is important during this process.

Identify Quality Improvement Opportunity: During this time, one should carefully reviewed the data with the staff to determine reasons why the threshold was not met or to identify trends or patterns. This is an important process that must be approached in a proactive manner. One must carefully look at the process to identify problems. Difficult questions often must be asked. Were enough resources allocated to perform this service within the timeframe required? Was appropriate priority given to provide this service within the timeframe identified? When obstacles are identified, options for removing them must be considered. Careful review with staff will identify opportunities that can improve the current process. These improvements must be identified, and then an action plan must be developed in order to implement them. An action plan identifies the problem, the data that were assessed, the analysis of the data, and recommended actions to be taken. This documentation is an important part of this process. It starts to tell the story of what the department is doing, what was found, and the way to plan to improve it. One important step in this process is to review this action plan to document whether the solution was successful in improving performance. This can be accomplished by using the same indicators to monitor performance after the action plan was implemented. This is an iterative process, constantly undergoing improvement.

Modify Indicator: When a quality improvement opportunity is identified, the indicator often will evolve. This is the time to redefine the indicator and the threshold, and then begin the process again. At some point one may decide that there is no longer the need to manage this indicator as intensively as in the past. At this point the indicator may be retired or it may be used to report performance. The only time when one would take any further action is if a threshold is crossed.

Case Study: A Project to Enhance IPM Services

In the following example, a case study reviews the way some of these concepts can be integrated into a complex process to monitor and improve scheduled IPM services.

Problem: Current monthly IPMs completion rate is 52%. Some IPMs took several months to complete. Some IPMs are not completed. IPMs included a variety of tasks, including electrical safety inspections, operation checks, and periodic maintenance procedures. Procedures are not well documented.

Goals: Identify timetable to complete monthly IPM services. Identify critical equipment to be included in this program. Deploy resources proactively to prioritize and complete IPMs in a timely manner.

Project team: All staff members participate in this project.

Initial Assessment: Reviewed the scheduled IPM for the past two years and identified several trends and patterns. All IPM services are treated the same—there is no prioritizing of services based on equipment criticality. There was no proactive process to distribute IPM workload. The initial indicator identifies only the number of IPM services completed by the end of the month. There is no process to help the staff to assign, prioritize, and close out scheduled IPMs.

Phase 1 Action Plan

1. Continue with the current process with the same indicator. It is noted that no threshold was determined. Additional information and time are needed in order to define a proper solution.
2. Review equipment management program to standardize equipment categories and assign a risk assessment based on equipment function, physical risk, and maintenance requirements. Define the population of equipment with high- and medium-risk, based on standardized risk assessment criteria. This was the first step to standardizing the program.
3. Verify that appropriate IPMs are scheduled, define the specific procedures to be used, and identify estimated time to complete. This would provide an opportunity to project specific resource requirements for each month.
4. Provide staff training on the new risk assessment process and how IPMs are processed.

Second Assessment: Once the first phase was completed, the projected IPM schedule for the year was reviewed. With a standardized database, monthly workload projections could be determined based on risk category. IPM schedules will need to be modified to distribute workload better (Downs and McKinney, 1991). The indicators need to be revised and appropriate thresholds developed based on risk assessment. Proactive IPM assignment to staff and monitoring of IPM status is required.

Phase 2 Action Plan

1. After assessing the existing IPM schedules from an equipment category perspective, these inspections are distributed equally throughout the year. Peak workloads that would require significant resources to be allocated for only IPMs, such as anesthesia machines, were identified throughout the year. In this case, these IPMs were scheduled quarterly—all of them on the same month—and required a significant amount of staff time to complete. By doing a third of these each month, the monthly workload and allocation of resources could be better managed while still providing quarterly inspections.
2. Program indicators with thresholds were determined for high- and medium-risk equipment categories. All of the high-risk equipment and 80% of the medium-risk equipment were to be completed within four weeks. Indicator data are posted at the beginning of each week, identifying the number of IPMs completed during the last week (per risk category). Weekly completion goals were established at 25% of the scheduled high-risk equipment and 20% of the scheduled medium-risk equipment.
3. IPMs are no longer assigned by management but are selected proactively by the staff at the beginning of the month. Staff develop a proactive plan to schedule this work to be completed weekly.
4. Provided opportunities for the staff to meet and review this process, make observations, and recommend future actions.

Third Assessment: After the second phase, the staff felt that they had a better understanding of what was required, and they were provided with tools to monitor this task. Additional procedures were needed to define ways to close scheduled IPMs if they were not completed during the four-week interval. Monthly review meetings provided opportunities to assess the services provided and to identify opportunities to improve the services.

Phase 3 Action Plan

1. Define procedure to close out an IPM at the end of the month. High-risk equipment had to be completed. Medium-risk equipment could be canceled if there were no equipment repairs within the past three months and the last scheduled IPM was completed or if the equipment could not be located.
2. Continue to use the program indicators and thresholds to monitor performance on a weekly basis.
3. Quick monthly meetings were held to review the IPM indicators for the past month, identify any trends or patterns, and review the IPM scheduled for the next month.

Process Review: This process took over a year to implement. When it was completed, there was a defined process to manage IPMs within the department, and all staff were trained as to its use. Workload was better distributed throughout the year. Standardized procedures were identified defining what was to be done and how long it took to perform these tasks. Workload data were identified proactively and distributed by staff for completion. Many opportunities for quality improvement were identified based on defining the services provided and reviewing the data collected, thus resulting in improved quality, productivity, and timeliness of service.

The Future

Successful clinical engineering departments have adopted many business practices to identify high-quality and cost-effective performance (Furst, 1986; David and Rohe, 1986; Bauld, 1987; Betts, 1989; Lodge, 1991; Mahachek, 1987; Mahachek, 1989). Effective utilization of program indicators with appropriate analysis of thresholds, trends, and patterns is an important tool in this process. When thresholds are exceeded or trends and patterns identified, a potential quality improvement opportunity exists. Comparing comparable indicators with other programs will provide opportunities to benchmark performance and to identify best practices for implementation. This process will continue to evolve, especially as tools become available to provide complex analysis of the data gathered in your database. One should not be surprised if in the future, software applications will assist in the identification of equipment for replacement, based on different indicators assessing multiple data points captured from information included in the equipment-management program.

Acknowledgement

The author had the opportunity to work for seven years with Robert L. Morris, PE, CCE, at the Department of Clinical Engineering at Oregon Health Sciences University. During that time they collaborated to develop many clinical engineering management practices, some of which are described in this chapter. Although Bob is no longer with us, his spirit lives on in the knowledge and enthusiasm for clinical engineering that he passed on to others.

Personnel Management

James O. Wear

Veterans Administration
North Little Rock, AR

Personnel management is an important role of a clinical engineering director. Although a clinical engineering department might have a maximum of 10–15 employees, the personnel management can comprise a significant portion of the director's job.

The director needs to establish an appropriate staffing level and to monitor this staffing level. Appropriate job descriptions must be written and modified as the technology of the hospital equipment that is being maintained changes. The recruitment of staff is a function of the director, as is selection from the pool of recruits. Having a good retention program so that there are no vacancies to fill over a period of time can reduce this part of the job.

Supervision of the staff is an important function to ensure that the engineers and technicians are motivated to provide good customer service and maximum productivity. A fair evaluation of the individuals, including their customer service and productivity, is an important aspect of the retention. At the same time, there must be appropriate compensation.

One important part of any clinical engineering program is that there is some pathway for career development and a career ladder that employees can climb. Without a career ladder, it is more difficult to retain employees because they will seek promotions and more challenging job opportunities elsewhere. Where technicians and engineers may belong to a union, the director must maintain appropriate management-labor relations.

Staffing Levels

Most hospitals are understaffed in their clinical engineering departments. This means that the work of the department director as a manager is important and that scheduling and establishing priorities is critical. In the clinical engineering department there will be clinical engineers, biomedical engineering technicians (BMETs) and clerical support. BMETs may be called "biomedical equipment technicians" or "biomedical electronics technicians." A department may not have individuals in all of these positions but all of these functions must be carried out. Instead of a clinical engineer there may be a senior-level technician as director of the department and instead of clerical staff, the BMETs may be doing their own clerical work. The roles and responsibilities of each of these will be discussed below.

When reviewing a staffing situation for a clinical engineering department, there are at least four situations. The first one may be staffing a brand new hospital, which has just been built and equipped. This will require developing a staffing program over a period of time because the staff requirements will not be as great initially (with new equipment) as it will be as equipment ages.

The second situation is for a hospital that has no in-house program. This is similar to a new hospital except there already is equipment in place that needs to be maintained, and clinical engineering needs to develop inputs on new purchases. This requires staffing a full department as quickly as possible but also has the opportunities to show real savings as the equipment is being maintained with service contracts or on-call service.

The third situation is for an existing program that is a poor clinical engineering program. This is the worst case that a manager can face from a staffing standpoint. Generally it is not possible to go in and eliminate employees and then replace them. This situation requires analyzing the staffing needs and matching that with the existing staff and determining how the gaps can be filled with training or the recruitment of staff as that opportunity becomes available.

The fourth situation is staffing in an existing program that is a good program. This program probably already will be well staffed, and therefore the situation becomes one of maintaining the staffing level and increasing it as needed.

The hospital size is a factor in the staffing required but probably more important are the amount of equipment and the sophistication of the equipment. Some of this can relate to the type of hospital. Most hospitals are general medical and surgical hospitals. They range from very small to large, tertiary-care units, but they primarily provide acute care. There are also long-term care facilities, which are primarily psychiatric hospitals, and which may have a large number of patient beds and not a large amount of instrumentation. Most large, general medical and surgical hospitals also have a number of psychiatric beds. If a

hospital is a teaching hospital, then it will have more equipment and more maintenance needs because a lot of students and interns are using the equipment. This is where different people and more users of the equipment increase the wear and tear, and no user is actually responsible for keeping the equipment in good condition. A teaching hospital will also have a significant amount of research, which will involve some unique equipment as well as some needs for modification of equipment. A hospital with significant research activity has some definite clinical engineering needs above what a general hospital will have, in or outside of the maintenance area.

One of the first steps in ideally developing the staffing levels, as well as numbers of staff, is the use of a skills assessment. There are six steps in developing the skills assessment: (1) to identify the competency required; (2) to build profiles of staff; (3) to assess the existing employees; (4) to identify gaps between the profiles and the employees; (5) to identify development options; and (6) to follow through to meet the competency needs.

The first step is to decide on the equipment that will be maintained and the other functions (e.g., equipment evaluation, service training, and contract management) will be performed. Next, one breaks these functions down into the competencies required. If individuals are going to maintain radiology equipment, they need to have the following competencies: 1) a knowledge of X-ray theory; 2) a knowledge of the operation of X-ray equipment; 3) good digital electronics; 4) computer operating systems; 5) networking; 6) general mechanical skills; and 7) radiology quality control. Similar competencies will be required for any category of equipment that is to be maintained.

Some of the same competencies are required for contract management, even though the people are not actually performing maintenance on the equipment. In addition, they must have good oral and written communication skills. They must have basic contract knowledge, including knowledge of how to write the appropriate specifications into a contract, and a sense of what to do whenever the contractor does not meet the terms of the contract.

To provide support to the clinical staff in evaluating equipment requires a general overall knowledge and an ability to read and interpret specifications on equipment. It requires good communication skills for dealing with the clinical staff and gaining their confidence.

In-service training is an important function of the clinical engineering program and requires special communication skills and knowledge of educational techniques. It requires learning how to use the appropriate visual aids and being able to evaluate whether or not people have learned the subject. It requires an ability to gain the confidence of the clinical staff or any other staff members that are being trained. This requires a broad knowledge of equipment if staff are being trained on the use of equipment, as well as an ability to read manuals and to develop meaningful training.

After the competencies are developed, one must develop profiles of staff that would be desirable to have those competencies. For instance, if someone is going to maintain intensive-care equipment and will be responsible for training the staff in the use of the equipment and electrical safety, then the individual would need the appropriate competencies for maintaining the equipment and for training. It should not be assumed that if someone is good at maintaining equipment, he is a good trainer or has good communication skills for working with clinical staff.

The next step is to assess the current employees to see whether any of them meets the profiles that have been developed. After looking at the competencies of employees, one might adjust the areas that they work in so that they come closer to the profiles needed. This could be done with a matrix of competencies needed with the competencies of the existing staff. One detail that should be considered here is whether personnel have competencies that are not currently being utilized either from previous work or previous training. It could well be that existing staff is being underutilized with the skills that they have.

After assessing the existing employees, one will find gaps in what exists and what is needed among the staff. For instance, there may be someone who has all of the technical skills for maintaining equipment in the clinical lab but does not have the skills to train people in that area. A person may be very good at monitoring a contract but might not have the skills for developing the contract. In a maintenance area, someone might be capable of maintaining analog X-ray equipment but might not have the required skills in digital electronics to maintain the newer digital equipment.

After looking at the gap analysis, one must identify what options are available for developing the competencies. If there are vacancies on the staff, and thus the opportunity to hire new people, then one can recruit to fill these gaps. The recruitment must be combined with

profiles so that individuals are hired for the profile desired and not to fill gaps that have no relationship to each other. With an existing staff, one must consider ways in which personnel can be trained to fill the gaps. For instance, with a person who is good at maintaining clinical lab equipment but has no experience in teaching, one must assess whether they have the appropriate personality for teaching. (If so, they can be trained in teaching techniques and evaluation.) The individual who is good at monitoring a contract can be trained to write statements of work and can work with the contracting office to develop a meaningful contract. The X-ray technician who has good analog experience can be trained in digital electronics and then can be trained to maintain newer X-ray equipment.

After each of the options has been looked at and developed, the critical factor is in following through with filling these gaps from recruitment or training existing staff. Priorities will have to be established because everything cannot be done at once. Establishing priorities will depend on the equipment that must be maintained, including the sophistication and amount of the equipment. The sophistication of the equipment will have more of a bearing on the skill level of the staff required than the number of staff. In fact, some of the more sophisticated equipment might have fewer maintenance problems due to high reliability and built-in diagnostics. However, it will require a more skilled technician to maintain it.

The amount of equipment will have the biggest bearing on the staff required. This can be considered in terms of the total dollar value of the equipment as well as in terms of the number of equipment items. The best measure is probably the number of items of equipment; the more pieces of equipment that must be maintained, the more technician time will be needed. This will require more time for inventory-finding the equipment as well as training users.

The external resources that are available are another factor that must be considered. At times it is more cost-effective to contract for maintenance of equipment.

There are some rules of thumb for the numbers of staff members required. They can be useful when there is no other information available. One BMET for every 100–150 beds was a good ratio in the early 1990s. But as more and more outpatient services are performed, this number is less reliable. Keeping one BMET for every \$1,000,000 in equipment value is another rule of thumb. Of course, that depends on what kind of equipment a hospital has. Furthermore, as hospital equipment has become more expensive, that number is probably higher today. Another ratio that has been used is one BMET for every special service area, such as intensive care, clinical lab, or radiology. Again, this depends on the amount of the equipment or the size of the services. Another figure that has been used is one BMET for every 400 items of equipment. This works out reasonably well in a large facility that has several thousand medical devices.

In looking at staffing from this standpoint, one supervisor for every 8–10 BMETs and one clerical person for every 8–10 BMETs would be appropriate.

It is tempting to say that any size hospital needs to have one technician to maintain equipment or someone who oversees contracts. However, if a hospital has one technician, it must have some method for backup because that technician will have vacation, sick, and training days. Therefore a facility must have two technicians or an arrangement to have outside coverage by service from vendors or possibly a sharing agreement with another hospital.

The best tools for determining staffing needs are workload data and historical maintenance information. Historical work order information provides types of equipment that need to be repaired as well as estimates of the amount of time required for different repairs. One can consider preventive maintenance, or so-called scheduled work, to determine the number of staff hours that are required. However, the preventive maintenance must be viewed realistically because no hospital can accomplish all preventive maintenance that manufacturers recommend. Appropriate preventive maintenance program must be developed to avoid too little or too much expenditure of human resources. The hospital's vacation policy must be considered with projections for sick leave and training, to account for the amount of hours that are available for technicians.

The Department of Veterans Affairs in the U.S. has 172 hospitals with about 50,000 beds, about 100 clinical engineers, about 1000 BMETs, and about 100 clerical staff. They have approximately \$3 billion in medical equipment. Most of these facilities are teaching hospitals. Some are relatively small—fewer than 100 beds—but most are in the 250–400-bed range. Looking at these data, there is one engineer for about 10 BMETs; there is one engineer for 500 beds, and one engineer for \$30 million worth of equipment. At the same time, there is one BMET for 50 beds, and one BMET for \$3 million worth of equipment. The VA maintains over 90% of this equipment in-house at an annual cost of about 4% of the acquisition cost of the equipment.

In a clinical engineering program there are several levels of positions. Table 51-1 lists and describes these different positions, based upon annual salary surveys published in the *Journal of Clinical Engineering*. The biomedical engineering technician starts as a BMET I and can progress up the career ladder to BMET II and BMET III, and to BMET specialist, which involves working in a particular area of medical equipment, and to BMET supervisor.

An engineer may start as a clinical engineer (junior level) and, with experience, may become a senior clinical engineer. A clinical engineer also may be a supervisor. In the top management position will be a clinical engineering director who could be a clinical engineer or, especially in smaller hospitals, a senior biomedical engineering technician.

Table 51-2 is the summary of the work done by BMETs and clinical engineers in hospitals, based on a recent *Journal of Clinical Engineering* survey. It lists the percentage of time that someone in each of these categories devotes to particular job functions.

Figure 51-1 is a representation of a career ladder for a clinical engineering department. It shows the way a BMET can progress up the levels of BMETs or can, with additional education, become a clinical engineer.

Education

A BMET might have military experience. The United States has the largest training program for these technicians. They might come from a one-year certificate program either

electronics or biomedical equipment technology. Increasingly, they have a two-year associate's degree either in electronics or in biomedical engineering technology. Many of those who have military experience have achieved the associate's degree through affiliations that the military has with colleges, or through the Community College of the Air Force. A few BMETs will have bachelor's degrees, but typically those will be in nonrelated fields.

Recruitment

Two of the best areas for recruitment of biomedical engineering technicians have been the U.S. Army and Air Force. They had separate training programs, but a few years ago they were combined into one training program in Wichita Falls, Texas. Their technicians receive extensive electronics training and extensive training on medical equipment, including X-ray.

Another source has been community colleges that offer an associate's degree with specialization in biomedical equipment or biomedical electronics technology. These typically have been small programs with 10–20 graduates each year. There is considerable variation in the quality of the programs because there is no accreditation, as such, for a biomedical equipment or electronics program. Some of the programs are accredited as electronics programs. The primary emphasis of these programs has been on electronics, and the depth of the biomedical equipment depends upon the availability of equipment for the students to work on. The better programs have internships (of a semester or more) with hospitals so that the students obtain real-life, hands-on experience. At any given time, there are 30–40 of these programs in the U.S.

The recruitment of clinical engineers is more difficult because most programs in the U.S. that train biomedical engineers train primarily in the areas of research rather than in hospital clinical engineering. Some programs that have had hospital-based internships have conferred master's degrees in clinical engineering. Many clinical engineers are at the bachelor's-degree level and have been recruited from electronic engineering programs. One of the best sources of recruitment has been to find a junior engineer or a second engineer in a hospital. They will have gained the clinical experience from work and will have learned to apply their engineering skills in the clinical setting.

One detail that makes the recruitment of technicians and engineers difficult for hospitals is compensation. In general, these individuals can obtain higher-paying jobs outside of the hospital, with the exception of some specializations such as imaging technicians. Medical equipment companies generally will pay more than hospitals, but candidates frequently are not interested in jobs with the former because of the travel that is required. In fact, sometimes good sources of recruitment are companies where a technician has decided that he no longer likes to spend the time traveling yet enjoys working with the medical equipment.

One of the problems of recruiting good technicians and engineers is the hospital working environment. Frequently, individuals cannot stand the smells, sights, and sounds of the hospital setting. The sight of blood, and the fact that patients die, can be unsettling to some, as can the psychological stress of working on a medical device and realizing that someone's life may depend on how well that device is repaired. Some people, interested in helping others, gravitate toward the medical field but are not interested in being a nurse or a physician. Instead, they chose the psychologically rewarding fields of biomedical engineering technology and engineering.

Retention

Retention is important in any field, but particular emphasis must be placed on retention when compensation is not as high as in other places and when there is a significant investment of on-the-job training. This is true with the clinical engineering staff. One of the best areas for retention is the continuous training of technicians and engineers to help them meet the challenges of changing technology. Being exposed to, and working with, some of the newest technology in the medical field helps with retention. Technicians especially like the freedom they are given in a well-managed program to work as part of the medical-care team with given departments.

Motivation

Motivation should be one of the criteria in hiring clinical engineering staff. A good program depends upon individuals who are self-starters and well-motivated to help the clinical staff in the delivery of patient care. Motivation is enhanced by developing a relationship where the clinical engineering staff is part of the health care delivery team and where caregivers can depend upon them to do whatever it takes to keep the equipment functioning. One of the motivations for BMET and clinical engineers is that they perform most of their work in the clinical setting, rather than in a shop and therefore that they are able to see the results of their work and its impact on patient care.

Labor and Management Relationships

Most hospitals are not unionized, but where they are, supervisors and management must pay more attention to issues in which the union might become involved. Where there is a union, there will be a union contract, and all levels of supervision must be knowledgeable about the contract. There should be no difference in the management of a program where the staff belongs to a union and a clinical engineering department where the staff does not belong to a union.

Table 51-1 Generalized Job Descriptions

<i>Position</i>	<i>General</i>	<i>Direction received</i>	<i>Education level</i>	<i>Certification</i>	<i>Average years of experience</i>	<i>Supervisory responsibilities</i>
BMET I: Biomedical equipment technician I (Jr. BMET)	An entry level or Jr. BMET. Has no or minimal related or equivalent experience. Performs skilled work of routine difficulty under close supervision. Fills out report forms. Primarily performs preventive maintenance, repairs, and safety testing.	Works under close supervision. Receives specific and detailed instructions. Work is checked during progress and is reviewed for accuracy upon completion.	Associate of science degree (58%) No degree (31%) Bachelor's degree (11%)	Not certified	2.2 years	Not a supervisor
BMET II: Biomedical equipment technician II (BMET)	Under general supervision, performs skilled work of average difficulty. Has at least several years of related or equivalent experience. Has good knowledge of schematics. Maintains records and makes reports. Primarily does preventive maintenance, repairs and safety testing. Can give staff training on equipment safety and proper operation. Selects and requisitions needed parts; coordinates repairs with outside firms.	Works independently in repair and preventive maintenance programs. Receives general supervision.	Associate of science degree (68%) No degree (24%) Bachelor's degree (8%)	About 19% are certified	6.5 years	Might be assisted by BMET I or other technicians, but is not a supervisor.
BMET III: Biomedical equipment technician III (Sr. BMET)	Works in repair, preventive maintenance and incoming inspection. Has a significant amount of experience or training. Performs highly skilled work of considerable difficulty. May specialize in certain types of equipment. Skilled with test equipment, schematics, service manuals. Can give staff training on equipment principles of operation and safety. May participate in selection of new clinical equipment.	Works independently under minimal supervision.	Associate of science degree (56%) No degree (30%) Bachelor's degree (14%)	About 41% are certified	11.6 years.	Works independently and is not a supervisor. Might be assisted by other technicians.
Equipment specialist: RES or LES	Works in repair, preventive maintenance, and incoming inspections. Has specialized training and experience on Radiology (RES) or Laboratory (LES) equipment. Performs highly skilled work of considerable difficulty. Has comprehensive knowledge of practices, procedures and specialized equipment. Highly skilled with specialized test equipment, schematics, service manuals. Can perform staff in-service training on principles of operation and safe use of specialized medical equipment. Might participate in selection and management of new clinical equipment or systems.	Works independently under minimal supervision.	Generally an associate of science degree or higher	CRES and CLES certifications available from ICC		Works independently under minimal supervision. Might be assisted by technicians or other specialists, but is not a supervisor.
BMET supervisor (A BMET with supervisory responsibilities)	Supervises peer or subordinate BMET workers. Has a significant amount of education or training or equivalent experience. Performs highly skilled work of considerable difficulty. Coordinates, schedules and assigns work for others. Might specialize in certain types of equipment. Has comprehensive knowledge of practices, procedures, and types of equipment. Skilled with test equipment, schematics, and service manuals. Continues to perform highly skilled repairs but also has a wide variety of professional level responsibilities.	Usually reports to a department head.	Associate of science degree (62%) No degree (21%) Bachelor's degree (17%)	About 46% are certified	13.5 years	Supervises other BMETs and support personnel. In some smaller hospitals or departments, might be the department head.

Clinical engineer (CE)	Works in design, modification, analysis, equipment selection, evaluation, planning, performance testing, or R&D. Performs engineering-level work of considerable difficulty. Can manage the process of high-tech medical equipment selection and acquisition. Has the capability to design and modify medical devices and to perform analysis of devices and systems. Manages medical equipment within the patient-care setting. Performs a broad range of professional level tasks. Can provide extensive training and in-service education.	Works independently under minimal supervision.	Is usually a degreed engineer. Bachelor's (61%) Master's (35%) Ph.D. (2%) Note: a few non-degreed or associate degree individuals are pioneers in the field or have been certified by the ICC as clinical engineers.	About 21% are certified.	8.5 years	Works independently and is not a supervisor.
Clinical engineer supervisor (A CE with supervisory responsibilities)	A Clinical Engineer that supervises BMETs or peer and subordinate CEs. Is usually a degreed Engineer. Has the capability to design and modify medical devices and to do analysis of devices and systems. Performs a broad range of professional level tasks including pre-purchase planning and evaluations, in-service programs, coordination of services, and a significant amount of supervision.	Reports to a department head	Bachelor's degree (52%) Master's degree (42%) Ph.D. (6%)	About 16% are certified	13.9 years	Supervises BMETs, CEs and support personnel, but is not the overall department manager
Manager or director of clinical biomedical engineering department	The department head of a clinical or biomedical engineering department is usually designated a "manager" or "director." (Most such departments report directly to hospital administration.) Most of these department heads are educated and experienced as clinical engineers or BMETs. Others are educated in business administration or hospital administration or may have extensive health care supervisory experience gained in other hospital management positions. The department head must have a significant amount of technical or management education or equivalent experience. They have the skills necessary to manage the process of high-tech equipment selection and acquisition; manage the maintenance and repair of all hospital high-tech equipment; participate in or direct an equipment-related incident and risk-management program; monitor and control department cost-effectiveness and productivity; conduct planning and budgeting; coordinate with other departments; plan and direct department development; and supervise others.	Usually receives direction directly from hospital administration, but in some cases reports to the head of a larger department.				Supervises BMETs, CEs, and support personnel. Participates in hiring process, reviews and disciplinary actions. Is the overall department or group head.

Table 51-2 BMET and Clinical Job Responsibilities by Percentage of Time

Position	BMET I	BMET II	BMET III	BMET specialist	BMET supervisor	Clinical engineer	Clinical supervisor	Clinical engineering director
Repairs/PM/Safety testing	73%	69%	66%	68%	29%	24%	13%	12%
Clinical support	3%	5%	6%	6%	6%	14%	9%	7%
Incoming testing	5%	5%	5%	3%				
Receive training	4%	3%	3%					
Provide training			4%	4%	4%			
Coordinate outside services				4%	5%		7%	7%
Purchasing	4%	4%				5%	7%	
Pre-purchase evaluation						10%		6%
Supervision of others					25%	6%	25%	27%
Department development					9%	9%	14%	18%
Other	11%	14%	16%	18%	22%	28%	25%	23%

Among issues that supervisors must be cautious about in a union shop are work assignment and ensuring that the workload is equitable and within everyone’s job description. The fairness issue extends to training and promotional opportunities. As management is open to a grievance under a union contract, all of these areas must be well-documented. When disciplinary action is taken against an employee, he will have the right to union representation, which must be honored appropriately.

Another major area detail about a union contract, over which the shop supervision has little control, is the periodic negotiation of the contract. It occurs with the hospital management; major issues include compensation and benefits. In most cases, this is a contract for all clinical employees or, at least, those who perform engineering functions. In most cases, as long as supervision and management treat all employees equally and fairly, there should be no issues with regard to labor and management relationships.

Management

Supervisors and managers must be able to measure what happens in their organization. If a function cannot be measured, then it cannot be managed. Managers are responsible for planning the workflow of an organization, organizing ways in which the work can be accomplished, and determining the staff needed. However, their main function is team-building in order to achieve the needed results.

Managers cannot do all of the work, so they must work through people and with people, so they must develop the people who work for them. They must be able to realize the human potential of each employee they have and to recognize the desires of those employees. By developing personnel for better work and new tasks, they will shape the organization to accomplish what is needed.

As managers cannot do all of the work, one of their more important functions lies in delegating. Delegation is the way that one works through people. At the same time, this does not mean that they delegate something and forget about it. Delegation is an art that a manager must learn. When an assignment is delegated, it must be explained thoroughly, and a manager must ensure that the employee understands the explanation. If there are any potential problems with the assignment, they must be identified at the time of the assignment or as soon as they are recognized. Clearly defined checkpoints should be

agreed to by the manager and the employee; next, the assignment should be summarized so that both the manager and the employee will understand it. The manager must not forget the checkpoints for the assignment because these are opportunities to measure the work that is accomplished and to encourage and evaluate the employee.

One of a manager’s important roles is to build a team and then to coach and maintain that team. The team must learn to be dependent on each other. Team members must be aware of the fact that they are a team and of ways in which they can work together. This awareness will give them the power to work and to achieve the best results. Team members might need to be selected for their willingness to work as a team. This is where the manager must have the insight into the personalities and desires of the employees.

The manager must establish a working environment for the team. In other words, one of management’s roles is to remove obstacles that would prevent the team from functioning. A team must know and understand the environment. They must trust the manager, and both the team and the manager must be committed to teamwork. All of the team members and management must cooperate for the team to develop and to produce maximum results.

A manager should expect high productivity from a team. The team should be expected to be more creative as it works together. The team should be able to be better at problem solving as members build on each other’s strengths. As a team accomplishes work that members probably could not have accomplished individually (or at least not in as good or as timely a manner), the members should gain personal satisfaction. By working on the team and building on each other’s strengths, each member will have increased personal growth and will have become a stronger member of the team.

The manager becomes the coach of the team, like the coach of an athletic team. He gives the team and individual members credit. The manager will provide constructive criticism, and at the same time they must be able to take criticism from the team. The manager must have good listening skills so that he can listen to the team (especially to the individual members) and can understand their personal needs. The manager must set a good example and must develop open communication with the team so that he listens and discusses the work with them. He must care for each one of the team members and must be able to mediate disputes between the members of a given team or between the members of different teams.

The bottom line comes down to the manager taking the blame if the team does not accomplish the work, in the same manner that a coach takes the blame for an athletic team’s loss. At the same time, if the work is accomplished well, the team receives the credit.

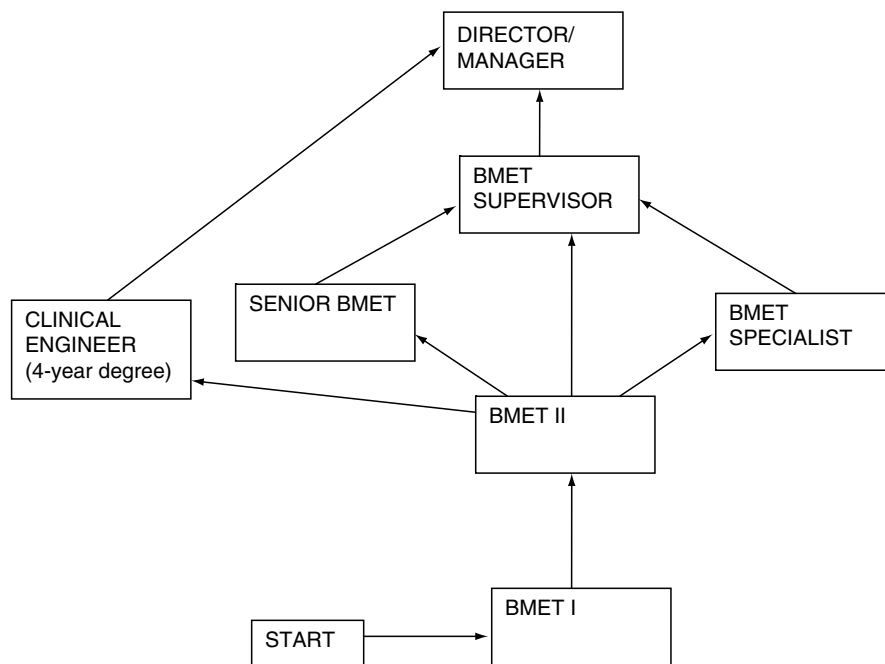

Figure 51-1 BMET Career Paths.

Performance Evaluation

In order to evaluate an employee's performance, there must be some understanding and agreement with the employee about what is expected from him. Evaluations can be performed in several ways. Peer evaluation is one way that is especially useful in the case of teams; team members can evaluate each other. A hospital can use customer evaluation. This is a critical part of the overall evaluation of the clinical engineering department as well as of the individual employees. A customer evaluation can be conducted by a periodic survey of the departments.

Productivity

The manager must be knowledgeable about productivity and might even need to provide management with reports on productivity. However, productivity is defined in different ways and is difficult to measure accurately. One can measure changes in productivity once it is defined and how it is measured.

One of the necessary details is the amount of time that is available for the technicians. Table 51-3 shows a breakdown of an employee's time, based on five eight-hour days per week, for 52 paid weeks. Accounting for holidays, vacation, average sick leave, and two 15-minute breaks per day, one has 204 days available, or 78.5%.

This example is for a senior technician working for the Department of Veterans Affairs, where the employee has 26 paid days of vacation. A more typical example might be 10 days of vacation, which would change the calculation to 220 days available, or 84.6%. Productivity, therefore, is based on time paid. The absolute maximum that an employer could realize from an individual would be this percentage.

Table 51-4 shows data on nonproductive or lost time for the average industrial worker and for maintenance workers in the Department of Veterans Affairs' Medical Centers (VAMC). This is not just for biomedical engineering technicians but for maintenance workers in general. Data were taken from surveys of supervisors who provided estimates. The VAMC supervisors did not report any idle time. Lost time, or nonproductive time, is any time during which the employee is not making repairs, consulting with staff, or in maintenance-related training. This is an area where a manager can work at reducing some of this lost time, and at increasing productivity.

Productivity relates to efficiency. The more efficient a program is, the more productive it will be. Output divided by the input is a simple definition of productivity. Of course, the final results depend on the ways that output and input are defined.

One of the details that must be considered in discussing productivity is what one considers to be a productive task. The following are some definitions of tasks:

- *Productive direct* are items like repair, installation, inspection, and in-service training.
- *Productive nondocumented* are the same items as productive direct, but there is no record of them. These might be small repairs and informal discussions.
- *Productive indirect* are items that are not directly related to repair. These include attending meetings, reading journals, and technical training.
- *Nonproductive* are vacation time, sick time, and breaks.

Going a level deeper into definition, *repair time* is the time required to diagnose a problem, to get parts, to make the repair, and to document the repair. *Travel time*, which is one area where productivity can be increased by reducing travel time, is included in this.

Table 51-3 Available time

Paid days 52 × 5	260
Holidays (U.S.)	10
Vacation	26
Sick leave	6
Breaks (1/2 hour per day)	14
204 days available or 78.5%	

Table 51-4 Maintenance worker lost time

	Industry	VAMC
Company practices	16.1%	17.4%
Idle	9.2%	—
Traveling	16.0%	6.0%
Personal	7.3%	3.8%
Early quits	4.4%	3.2%
Waiting	4.6%	4.4%
Instructions	4.4%	4.2%
Clean up	5.2%	5.6%
LOST TIME	67.2%	44.4%

Periodic maintenance time or *preventive maintenance time* is that time that is required to check the medical device for any defects and to perform any tests that are required, including electrical-safety tests. *Travel time* is the time required to go to and from a repair site. Because many devices in a hospital setting are repaired in the place where they are used, travel time can be a significant factor. *User down time* is the time when equipment could be used to perform work in the clinical setting but it is not available because it needs repairs. This does not include the time that equipment might be down at an off-hour when preventive maintenance might be being down. *User up time* is the time when the user is working and the equipment is available to be used. This is an important time to write into service contracts.

One method for presenting maintenance productivity is by showing that the maintenance percentage cost is equal to the cost of maintenance, divided by the inventory value.

Conclusion

This chapter indicates the importance of personnel management to a successful clinical engineering program. Various topics discussed emphasize areas in which the director of the department must develop skills. Communication, coaching, and team-building skills are the most important skills the director must have. Through personnel management, the director can create a working environment for a successful and highly productive department.

Academic Knowledge

Certain academic institutions have earned banners of excellence based on years of developing a turnkey product for the clinical engineering or health care marketplace (Baker, 2002). Employers are more familiar with the scholastic product of these institutions and rely on the premise that certain basic concepts will be part of the engineer's or technician's basic skills. It is not always the case, but there is a comfort level for the employer. An employer generally waits six months before making a basic skills assessment of a recent graduate, whether that graduate is from a two-year associate's program in applied science or a four-year bachelor of science program in engineering.

The management and maintenance of biomedical equipment is a dynamic and expanding career field, but it is a relatively small arena compared to almost any other profession. In this small field, the grapevine and the Internet rapidly convey information regarding academic institutions. If entrance standards and course requirements become diluted, an academic institution's long-held reputation can tarnish quickly.

Military-trained biomedical equipment technicians (BMETs) sometimes find themselves at a disadvantage if the employer has ties to other civilian academic institutions. Care must be taken, as well, in evaluating the military-trained BMET's skills because of the many variables involved in military BMET training (Wear, 2003). For example, the military emphasizes radiology training as its ultimate goal. If the BMET received that training but is assigned to a field-post aid station, BMET skills in radiology repair and maintenance will not have an opportunity to blossom. On the other hand, if a military BMET is assigned to a major medical center, that BMET will receive excellent experience and possibly additional training. Therefore, a wide variation in skill level is quite possible to encounter in military-trained BMETs. (See Chapter 9.)

Hands-on Skills

Generally, BMETs will receive more practical, hands-on training than will engineers, and they will continue to excel in bench work particularly if they receive training by way of original equipment manufacturer (OEM) or skills seminars. Clinical engineers (CEs) typically are more inclined to take advantage of opportunities to develop their public-speaking, communications, and management skills. They may also volunteer for OEM training and may tend to learn more rapidly than BMETs. Simply put, CEs are oriented toward problem-solving, while BMETs are task-oriented. Both skills are useful, and their value to the employer depends on the employer's needs, which ultimately are to address the needs of the clinical engineering department's customers. Skills requirements vary from facility to facility and from project to project within the same facility. Different skill sets are required, depending upon the mission of the health care facility. A clinical engineering department in an academically affiliated facility may support research, whereas a department in a specialty hospital may support devices used in cardiac procedures and organ transplants. The demands of the customer change the skills that are required in order to meet that customer's expectations. An experienced clinical engineering manager will seek opportunities to provide service to customers who are not currently satisfied. This could entail the identification and re-engineering of an inefficient process.

As new technology is introduced, BMETs and CEs must adapt accordingly by improving their skills and understanding of the technology. The CE manager is constantly engaged in the skills-identification process, striving to make the department more efficient. The core skills taught in academic institutions are basic building blocks upon which additional skills are placed. A manager who is a mentor is invaluable. The experience obtained from a good mentor can increase the opportunity for professional advancement and standing within a department.

As the health care facility expands its services to the community, the CE department must be versatile and must maintain pace. It must increase its visibility to clinical and administrative personnel. Developing communications skills will help with bridging the gap between clinical and administrative worlds and will facilitate the ascent of the career ladder.

The manager who keeps the work environment challenging finds that personnel enjoy the challenge and stimulation and that they derive job satisfaction as a consequence. Technical personnel, while performing enjoyable, challenging tasks, develop new skills and a sense of accomplishment and competency. Babcock (1991) states, "The professional's view of what is challenging must be reconciled with the needs of the organization, and the challenge to the supervisor is not just making wise decisions, but structuring them as much as possible to provide the desired challenge and then persuading the individual of their importance."

Accepting Risks and New Challenges—Developing Your Skills

Clinical engineering duties and responsibilities are generalized in the job description. Successful clinical engineering departments commit to tasks that other technical departments may consider an overcommitment of resources or beyond the scope of their technical expertise. Telemedicine (see Chapter 101), picture archiving and communications systems (PACS) (see Chapter 102), and computerized maintenance management systems (CMMS) (see Chapter 36) are just a few examples of the neohealth care technology without specific departmental boundaries. If the challenge of these new technologies is accepted, one should make a full commitment to ensure success. If one is concerned that the department will fail to demonstrate competency, one should not undertake the project. However, if the manager never ventures beyond the norm, the department and associated skill levels will reflect that lack of commitment.

Contacts and Networks

BMETs and CEs should be involved in their respective professional organizations and should attain certifications offered within the profession. (See Chapter 133.) A certification or registered license conveys a base of knowledge to fellow associates in the same profession. To those who engage in the debate over whether certification or licensure makes one a better technician or engineer, it must be stated that improving professional skills is not the goal of certification or licensure. It is, rather, a professional recognition that the certified or licensed individual has a proven core knowledge required of the profession. Numerous salary surveys have affirmed that those CEs and BMETs who are certified receive higher compensation (Baker, 2002).

Attending professional meetings and becoming involved in professional societies provides an opportunity to exchange professional and managerial information, discuss work environments, and explore standards of living. If an inspection by the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) is impending, discussions with fellow BMETs and CEs who recently have endured the process will be of value. Insight gained from these discussions can be shared with the hospital's team leaders.

Networking provides a link to best practices and benchmarking without having to reinvent the wheel. In short, it is an efficient and reliable management pipeline that often leads to lifelong professional associations. It can serve as a career-development tool and can provide insight for professional, management, and personal decisions. When utilizing a professional network, adhere to your professional ethics and avoid gossip channels. Always be considerate of the time constraints of those contacted, and strive for a *quid pro quo* relationship.

Resumes

Perusing a resume in connection with the hiring process provides valuable information about an individual's recorded achievements. It provides little information, however,

about the magnitude of those achievements and how well any needed skills would augment your department's performance. A personal interview and a resume provide a manager with about 50% of the information that is needed to make a wise hiring decision. There are several intangibles that determine the long-range success in the hiring process that cannot be analyzed with a resume and interviews. For example: Will there be a common chemistry that is required for all interactive technical partnerships to be successful? Will your service or product be enhanced? The best that a manager can hope for is that the skills have been identified for a probability of success in the hiring process. The other significant aspect of whether an employee will enhance the CE department's technical expertise and customer satisfaction is the work environment itself. This depends largely on the kind of a department that the manager has created or inherited, the manager's abil-

ity to motivate, and the proficiency with which the manager can bring out the best talents of every employee.

Management Styles and Human Resource Development

Alice L. Epstein

Greener Pastures, Inc.
 Durango, CO

Management of engineers and technological staff presents distinct challenges. Staff are highly trained, focused, and intense professionals with high degrees of self-motivation and direction. Managing the egos, vast skills, and individuality of such staff requires skilled, trained management who understand the way to mold staff into a cohesive team. The primary tasks of a technical manager will be to provide support and to facilitate, rather than to maintain a close hold on direction.

Technical managers need not be the individuals with the greatest intellect or ability to perform technical functions. While the manager must have a firm grasp on the concepts and science, it is more important for the manager to have the necessary skills to ensure that tasks are assigned appropriately and completed. It is more important that the manager facilitates support, such as ensuring that the group and individuals within it receive the training and support that are needed to progress and improve. Staff often can develop pockets of expertise that would remain isolated unless a technical manager were to facilitate dissemination of the expertise to others who might make use of it in their tasks.

The following sections provide specific information on subjects that are important to technical management and human resources.

The Evolution of Management Theory

The early twentieth century brought to the attention of industry the study of time and motion as a method to improve work-practice efficiency. Frederick W. Taylor introduced the concept of scientific engineering, in which he recognized that each task could be examined scientifically and rationally optimized to improve productivity. Taylor is a controversial figure in management history because although his innovations in industrial engineering paid off with dramatic improvements in productivity, he has been credited with destroying the "soul" of work and with dehumanizing factories. Taylor recognized the importance of training an employee to the highest level of his capabilities and the responsibility of management to prepare systems to enable the worker to work better and more quickly than he otherwise could. Taylor believed that workers should be taught by and that they should receive the "most friendly help" from their managers instead of being driven or coerced by their bosses or left to their own unaided devices.

The Ford Motor Company introduced production lines and injected monetary incentives (piece work and higher wages). Production improved, although it became clear that an excessive pace wore out workers in a short number of years.

Henri Fayol and Luther Gulick introduced variations of scientific management in the 1920s. They argued that the use of principles such as specialization of labor and hierarchical leadership structures would result in optimal organizational performance. Fayol's components included planning, organizing, commanding, coordinating, and controlling. Gulick's components were similar.

In the 1920s, Elton Mayo explored human relations by studying changes in productivity at the Hawthorne Works of the Western Electric Company. He noted that changes made to lighting, processes, and work breaks (up or down) resulted in an increase in productivity. He concluded that involving people in ideas and changes (even irrational or noneconomic ones) improves morale and productivity. Conclusions showed that:

- Complaints are not always about what they seem to be, but may be the result of some personal disturbance.
- All actions in an organization are given a social meaning. Perceived and intended meaning may be very different.
- The behavior of an individual in a job is the result of more than instructions or job descriptions. It is affected by personality, values, and attitudes expressed by co-workers.
- Worker status is very important and is determined by the way the worker perceives his working environment.
- There is an informal organization within any formal one. This is made up of relationships, communications patterns, and perceptions.

The scientific management perspective was attacked by Herbert Simon (1946), who argued that the principles of scientific management were vague and contradictory. Widely accepted, scholars turned toward the importance of specialization, chain of command, unity of command (one boss), span of control (optimum subordinates), and minimum authority levels.

Motivation was introduced as a management concept by A. H. Maslow in the 1950s. Maslow determined that all individuals have a hierarchy of needs:

1. Biological (the most basic): Hunger, warmth, rest
2. Safety: Protection from danger
3. Socialization: Love, affection, affiliation
4. Self-esteem: Autonomy, dignity, respect
5. Self-actualization: Realization of one's potential through competence, creativity, and achievement

E.H. Schein introduced the theory of the complex man in the 1960s. Schein believed that the study of management theory was too simplistic and that no single management style can succeed in improving the performance of all workers. The motives of an individual

can be extremely complex and liable to change over time. He believed that a high level of satisfaction does not necessarily lead to increased productivity.

In the 1960s and 1970s, Peter Drucker introduced “management by objectives” to include fundamentals of strategic management by setting objectives for staff and assessing their achievement. He believed that decentralization was imperative, in order to confront sudden changes and to take advantage of new situations.

Peter Senge, in the early 1990s, purported that those organizations that are capable of decentralizing leadership to enhance the capacity of all people to work productively toward common goals results in learning organizations being capable of rapid change. Only organizations that are flexible, adaptive, and productive excel. All people have the capacity to learn, but the structures in which they function are often not conducive to learning because they lack the tools and guidance for employees to make sense of situations they face.

Empowerment has always been perceived to be highly motivating and extremely efficient, but it is little used because leaders often desire and control power and efficiency. Throughout history, empowerment leadership was implemented when “getting the job done” took priority over control. Empowerment as a management style authorizes employees to perform their work without the need to seek approval from supervisors. However, it also holds employees accountable for their actions and the outcomes of projects they assume. Traditional management does not embrace empowerment because managers are reluctant to relinquish control. Effective empowerment programs require restructuring and relearning of responsibilities by managers and employees.

West Meets East

Management style, like society, generally varies from U.S. and European organizations to Far Eastern organizations. If we simplify styles, Western management style may be described as open, direct, and confrontational, stressing short-term profitability. Eastern management style stresses seniority, relationships, and family ties, stressing long-term profitability and employment. As globalization progresses and financial challenges arise, differences may shrink—perhaps taking the best of both styles and merging them into one, but more likely taking the features of both styles that improve the opportunity for economic survival.

Arthur Andersen and the Batey Research and Information Centre performed a survey in 1997 that examined the differences in management styles from the perspective of senior business executives (405) themselves.¹ While the results support the position that management styles continue to differ, the results also point to styles converging. For example, “respect by business community” and “commanding a good salary” were ranked first and second as indicators of a good manager by the eastern and western executives. While western managers place a great deal of emphasis on initiative and often make decisions unilaterally as “the boss,” eastern managers often prefer personal meetings and development of consensus. Western managers tend to stay within their bounds and focus on results rather than the way a task is completed, while eastern managers typically provide detailed goals, instructions, and schedules and look past their group assignment to the way their work might interact with other groups.

Most would agree that much of the globalization of the market is resulting from the expansion of western organizations into previously untapped or limited opportunities (markets and production capability alike). Eastern executives, while they may not embrace western methods, have studied these methods meticulously, and, as noted above, some have embraced particular features of them. However, western executives rarely receive training in eastern management styles, although there are exceptions. The challenges for eastern and western managers are to learn and to continue to be open to those practices in each of their respective regions that not only work within their primary domain but also in domains in which they may expand or otherwise contact. By coming to understand the history, rationale, and specific features of each style, engineering managers can adopt practices that do not conflict with accepted business practices to an extent that will result in project failure, loss of strategic alliances, or loss of technological and human resources. A simple difference in, for example, a western manager directly confronting an eastern participant in public about a disagreement (versus taking the time to discuss the issue on a personal level in private) can lead to irreparable damage to a relationship or alliance. Sometimes even the fact that damage has been done is not recognized by the manager until the long-term effects (e.g., dissolution of the alliance, drop in production, or loss of employees) become evident. Similar negative results could be expected if an eastern manager holds a tight rein on a western engineer rather than “letting him do his job.” Inclusion of women in the work environment remains highly divergent among some cultures. As the western management cultures have come to embrace and promote (by law) equal employment between the sexes, sociological differences in other regions of the world have a far different perspective on women in business and in religious activities in terms of what equality might mean. If you are a woman, these differences most certainly can affect your opportunities to work or to manage. From a western perspective, there currently seems to be no good answer to what we perceive to be a problem and an unacceptable inequality. Suffice it to say that new opportunities in the east (and elsewhere) must be carefully examined with respect to this issue, and they must be discussed among male and female executives to construct the organization’s approach to maintaining harmony within the organization.

The use of experienced mentors, external consultants who are familiar with the area and styles and training and education on these subjects can help to make the experience successful and enlightening.

Cultural Diversity

Engineering in medicine in the United States is a multicultural professional discipline. Trained engineering professionals and engineering professionals-in-training bring with them diversity in virtually every aspect of personal (e.g., language, religion, and home

life) and professional (e.g., education and exposure to technology level) experience. Add to this the globalization of industry and technology-related humanitarian efforts that are being made around the world; it becomes obvious how important it is for engineering managers to develop an understanding of the cultural differences and strategies for not only overcoming impediments but also for taking maximum advantage of these differences to promote project success. Major impediments can include:

- Poor quality of communication and understanding, leading to errors in technical and/or project development
- Inability to match personal sociological understanding and experience with that of the community, either when a foreign engineer enters the U.S. community or when a U.S. engineer enters a foreign community
- Application of incorrect risk/cost/benefit analysis to that community
- Inability to provide adequate support services (e.g., cultural food stuffs, religious services, and time within a day for purposes outside the basic U.S. business practice) to meet the needs of the whole professional for the cultural situation in which he has been placed

Typically, the engineering curricula have not set aside a substantial amount of time to address these issues. Similarly, not much time has been set aside within industry to prepare managers or working professionals for the sometimes difficult and sensitive tasks of addressing cultural differences. Even so, it has been our experience that the mutual intellectual basis of engineering, regardless of cultural diversity, can provide a solid background on which to seek and understand the nature of our colleagues, their needs, and the needs of their communities.

The first step in addressing cultural diversity is to promote the interest among engineering professionals and students in investigating and experiencing cultural diversity firsthand; it might come in the form of personnel exchanges, required learning, or side-by-side work experience. While the nature of our cultural differences can change from relationship to relationship, the willingness to seek out information on our own initiative and to ask questions when a matter may be unclear, and remaining nonjudgmental and receptive, can go a long way toward promoting understanding. Assigning mentors who already have experienced and successfully addressed what might be expected by the less experienced engineer is also an excellent method for addressing issues of cultural diversity. Such mentors not only can tutor the culturally diverse but also the less-experienced colleague who is experiencing cultural diversity for the first time.

The value of making use of cultural diversity also should not be minimized. Professionals who are involved in a culturally diverse project should seek out experienced colleagues who are likely to be able to contribute to the specific issues that could face management and the working professional. While a language barrier is an easily identified issue where the value of collegial intervention is understood, similar review of project goals and conceptual design can avert misunderstanding, errors, or failure of the project and personal or professional discontent.

The Creative Process

Many organizations make their daily profit on “meat and potatoes,” doing exactly what they have done best and routinely. There is nothing wrong with this as long as a predisposition to routine does not (1) impact on the ability of the organization to do things better, cheaper, or safer; (2) stifle innovation that could help to ensure future success or; (3) create an employment environment that stifles the creative nature of its employees so that an important part of their basic personality needs is not met. If the organization does not accept the challenge to do things better, cheaper, or safer, a competitor might arise and take that meat and potatoes off the table altogether. If the pipeline for new products, new projects, or new clients shuts down, the organization could slowly fade away or become a takeover target. If creative employees are not provided with an avenue for release, employees might leave or become ineffective when the organization needs them most.

The creative process is all about team building, teamwork, problem-solving, and productive creative thinking. If a group jumps into problem-solving or creative thinking without having built the team or having cultivated teamwork, many participants might feel stifled or might prefer not to express themselves freely if there would be a resulting negative impact on the creative process. Others might not know how to participate. Engineers need to have a concept and perception of team, and a recognition of their place within it, in order to feel routinely comfortable sharing ideas that have not yet been thought through fully. They also need to know that the process itself is not flawed; for example, that the process will catch an idea that seems to have potential but that is ultimately flawed before someone thrusts it into use without proper consideration. Conversely, they need to know that those ideas that have potential will not be ridiculed, shut down, or pushed aside because of one person’s viewpoint or shortcomings.

Some creative-process aficionados suggest that brainstorming should be a scheduled event, with limitations on group size and time allowances. While there is no reason not to hold such meetings, creative thinking actually occurs all throughout the day, the month, and the year. Cultivating an environment where brainstorming has a release that is supported at all times—even when the employee is at home or on vacation—may be a more effective way to capture those ideas that occur to special individuals throughout their employment. This might be in the form of cultivating an environment in which every employee is encouraged to write down their ideas when they arise and to provide various methods by which they can convey and discuss their ideas with others. Some creative thinkers do not create well on demand, but they can let their creative thinking flow when the environment is right for them.

Much has been said about the value of meetings, and certainly the increasing dependence on, and comfort with, e-mail and other communication venues impacts the need for face-to-face meetings. However, the arguments against face-to-face meetings must be weighed against the intrinsic value of face-to-face confrontation, reading a person’s body language for signals, and immediate and unguarded response. Many argue that face to face meetings are too costly. For example, we saw one argument citing that an employee

¹ Asia 21, 16-19, September 1997.

paid at \$40,000 per annum cost \$300–\$400 per hour in a meeting. Suffice it to say that the arguer was not the CFO, nor very good at math, in any event. Similarly, we have found that engineering professionals typically will go out of their way (e.g., attend a nighttime dinner meeting not on company time, although the company might purchase dinner) to participate in the creative process if the environment for the process is appropriate, and if viable creative outcomes are introduced.

Facilitators have developed some basic structures for brainstorming, problem solving, and creative thinking. For example, some programs have a first section where all ideas are taken, without any negative comment allowed. A second section allows for a period of private consideration by smaller groups. The third section brings all of the groups back together to examine their findings and to promote further discussion. It should be noted that not all groups or individuals will respond well (i.e., creatively) to a specific structure. The groups and individuals should help to determine the structure, with no “canned program” arbitrarily accepted without this input. It is like saying, “Hey, let’s all think creatively, but within this box.” We have seen some recommendations that managers should maintain a confidential file on each and every employee. The purpose of doing so purportedly is for the manager to monitor productivity for time-management purposes. While such activities might work well for operations that just “turn the crank,” they work poorly for the creative process. Usually it is an accounting/time-management professional who is interested in eking out greatest profitability from existing operations; unfortunately, there often is no place within their models for creativity, although their salaries and those of all within the company might ultimately depend upon that creativity and the basic operations that might have resulted from past creativity.

In brief, the creative process should be cultivated in every organization. While more attention to it might be provided in certain groups (e.g., research and development), it is important to recognize that creativity is part of human nature. Some more, some less, some in one manner, some in another, some that may be useful to the organization in its mission, and some that may not be useful to the organization, other than in cultivating a good work environment for all.

Communication Skills

As we recognize the importance of communication in bridging cultural-diversity gaps, communication affects all aspects of a business. Communications skills are essential to leadership. The ability of a manager to communicate and to relate organizational goals to the individuals to whom leadership is afforded is directly tied to the success of that manager. The manager of a technical staff must ensure that communications flow in both directions for success to be attained.

It is important to realize that communication can be oral, written, or interpreted by action – action of the company (e.g., lack of funding of what otherwise has been interpreted and projected to others as an important program or sector) or action by the individual (e.g., body language). If you provide a message that has one meaning but convey a different message by one of the other methods of communication, do not be surprised if staff become confused, outspoken in support or lack of support thereof, or frozen in place.

The discipline of risk management almost always regards written messages and documentation as more acceptable and indicative of desired practice than spoken messages; i.e., unless written messages and documentation are repeatedly not followed by actual practice over time—an unfortunate occurrence that repeats itself much too often. The actual message conveyed to different staff members might be mixed and very different as a result of the total communication package that one manager presents to staff, versus what that staff member might then impart to others, or versus what another manager presents. One simple example might be a senior management executive conveying to his research-and-development director the need to complete a project within budgetary and time constraints; the director might convey the message, but mixed, by averting his eyes from his engineering staff potentially interpreted by staff that one or both goals is unrealistic or that the result of an inability to meet the goals could result in unemployment.

Communication can be impaired by many different types of barriers. Physical barriers to good listening are often environmental; too hot, too cold, or distracting. Mental barriers exist in the form of stress, prejudice of the material or speaker, or rambling by the speaker. A manager should realize the existence of these barriers and should cultivate an environment in which such barriers are not likely to exist.

There are a number of counterproductive communication errors to avoid, such as:

- Failure to greet another
- Too little or too intense eye contact
- Making a person wait
- Accepting phone calls or working on other projects during a meeting
- Interrupting
- Using meaningless or confusing words or expressions
- Obfuscating or embellishing message
- Poor listening
- Constructing a physical or psychological environment that is not conducive to promoting honest discussion

These errors apply not only to discussions and communications within an organization, but also to communications (e.g., customer-service contacts) that the organization might have with others outside the organization. Some of these communication errors can be addressed within the organization if managers receive adequate training, understand ways to mitigate the errors, and receive constructive criticism based on actual practice. Confrontational-based criticism (during, for example, a salary review) without prior provision of adequate training and experience should be avoided; such activities indicate more of a need for the manager to be retrained in communication. A manager who is practicing the art of effective communication will never think or assume that staff members have all of the information that is essential to their satisfactory performance of job duties.

Mentors can make an important contribution to improvement of communication. If the mentor can be seen by the mentee as interested first in the professional development of the mentee, and perhaps only second in the success of the organization in the particular matter, the message of criticism may be communicated more effectively because the mentee might be better prepared to listen. Where it is clear by review or occurrence that communication systems have problems, outside consultants can be helpful.

It is important to understand and to support that listening is the responsibility of all parties—including very senior management, who might resist criticism of their abilities or systems that they have developed, or new hires, who might have had limited experience in listening. Listening requires concentration. Poor communication often results in sub-optimal performance.

The Written Word

Much of the writing that an engineer prepares may well be related to technical issues; for example, conceptual-design review, project-resource allocation, meeting details, service recommendations, or user instructions. Unlike personal, written communications that we may make to friends and family, business documents can be viewed as permanent records long after the projects for which they were written are completed, or long after the individuals who have composed or read them have departed from the organization. Similarly, unlike verbal discussions we may have with co-workers, clients or others, where a dialogue including an exchange of views is provided, written documents do not provide for an immediate exchange of information or concerns or for an opportunity to utilize the other methods of communication (e.g., body language or facial expressions) to confirm understanding or confusion. As a result of these and other factors, it is important that engineers be skilled in the art of business writing. Every engineering curriculum should teach technical writing, should address all manner of typical business documents, and should identify potential errors and methods for avoiding them. In addition, the employer should provide focused training on methods for and policies and procedures concerning business writing; mentoring to provide ongoing, unbiased criticism of actual examples of business writing can be very helpful.

One of the first questions to ask is “What type of document is it, or should it be?” For example, after receiving a user report from the field, regarding their perceived identification of a limitation in safe use of a product, it is important to consider which document(s) will best respond to address the issue(s) raised. A customer-service letter to the reporting client might be warranted—perhaps a memorandum to regulatory affairs, maybe a new user instruction, emphasizing the proper methods for the use of the product and the potential result(s) of misuse.

A second question to ask is “Who is the audience?” Perhaps the writing will be of a sensitive nature to in-house legal counsel, or to the user who is not an engineer or who is not a college or high-school graduate, or to a technical professional who must make a change in material or physical feature.

A third question to ask is “What is the goal of the written document?” It might be to help the user, who has seventh-grade reading skills, to understand how to safely utilize a product. It might be to place an attorney on notice that serious repercussions might be about to occur, or to convince senior management to fund a project, or to convey technical information or direction to a colleague or staff.

Once these three initial questions have been asked and answered, the tone and content of the writing can become much clearer. The writing can be direct, courteous, and sincere, can provide the appropriate emphasis, and can be written at a level that is appropriate for the audience. Emphasis can be in the form of word treatment (i.e., bolding, underlining, capitalization, and italicization) or word-smithing. It is important to avoid discriminatory language, obfuscation or embellishment of the issue, and overemphasis (e.g., yelling—CAPS in e-mails) when not indicated or necessary. It is important to identify the issue, to detail what is expected, and to stress the benefits to the reader. If you are confident in your viewpoint, it is helpful to stress that confidence.

Never forget that the document might appear where you least expect it. It might be read and interpreted by someone to whom you did not direct it. If, on second reading (a habit that all should embrace before sending a document), specific information included in the writing does not contribute to the goal of the document, it should be considered for deletion or revision until all that is left does contribute to the goal. If it is recognized that a document is particularly significant or sensitive, a “second opinion” might be worthwhile; sometimes this second opinion might even come from the primary audience to whom the document is addressed.

Remember that written documents might not replace the need for interpersonal discussions, meetings, or additional presentation vehicles (e.g., slides, videos, and training sessions). It is also important to be fully familiar with your organization’s position on company documents. Documents prepared for business purposes might be defined as business products, wholly owned by the business, and you might not be permitted to use or maintain these documents, even within your office. Many organizations have document-retention policies, and it is important to be familiar with them.

Mentoring

Mentoring is the provision of guidance from an experienced party to one who might be less experienced generally or who might be less experienced in specific areas only. The purposes of mentoring include:

- Orientation and policy and procedure introduction
- Technical training and development
- Professional development and diversification
- Error/issue management
- Unbiased, nonconfrontational and routine critique

Mentors might need to set aside management responsibilities; that is, if the business situation is such that the boss must also be the mentor, the professional mentor must be able to set aside many of the responsibilities of a boss in order to provide an opportunity for the mentoring process to work. While the process of mentoring is intended to assist the mentee, one oft overlooked aspect of the process is that mentors must be trained and must understand how to be an effective mentor. Not all experienced or exceptional engineers can be, without training, even an adequate mentor. Analogies include;

- While a person may be a great individual of high standards and knowledge, they might be a terrible parent.
- While a student might have expert potential, a poor teacher can obstruct the student's realization of their potential, perhaps for life.

Mentoring can be either informal or formal, and typically some degree of mentoring (which may be as simple as showing mentees that this is the way we do things) is better than none. Mentoring need not be provided by engineers solely within the mentee's group; mentoring by professionals within, for example, a local professional society, a separate division, or a separate group is often more acceptable because the relationship is outside the political constraints of employment. Most experts agree that compatibility and respect are the foundation of a mentoring relationship.

Providing attention to development of the mentor program and supporting all participants in the program can provide important advantages in job satisfaction, job performance throughout the management hierarchy, and employee retention.

Motivation

Managers might believe that employees only work for money or tangible rewards. But when asked which rewards make a difference, employees rarely list money at the top, instead identifying recognition, involvement in decision making, or interpersonal rewards. People perform better when their efforts are rewarded, although rewards need not always be financial. The manner in which you treat your employees can be an effective reward. Nonfinancial rewards include public recognition and praise, providing the opportunity to expand job responsibility, kind words in a performance review, and notification to upper management of an accomplishment.

One significant form of motivation is feedback. Feedback, positive or negative, should always be constructive. Praise is a nonexpensive method to increase morale, motivation, and productivity. Most people respond to praise by working harder. Those who feel unappreciated are likely to cut back their efforts, figuring that management does not care.

The manager should ensure that criticism can be clearly interpreted as criticism of behavior or performance and not of the person. Managers must take full responsibility for communicating to the employees their perception of the work. Meaningful feedback is immediate. One of the first things that managers should ask themselves before criticizing is determining whether the employee should be able to perform the requisite task with the current skills. If the answer is no, it is the responsibility of the manager and the organization to see that appropriate training is provided to that employee.

Educational opportunities and training can be effective motivators. They demonstrate that the manager recognizes the employee's potential, that they are interested in the employee's growth, and that they expect to expand the employee's participation within the organization. It is imperative that the value of the opportunity be recognized by the manager and understood by the employee. Time might need to be allotted in schedules and project assignments in order to get the most out of the education without the employee regretting being away from assigned work.

Motivated employees are those who are comfortable with their assignments and who believe that their managers value them. It is essential that performance standards be clearly specified in advance. If the manager and employees are not in agreement about what is expected, confusion and frustration are likely to result. The manager must clearly communicate individual and organizational goals. When assigning projects, it is important to spell out assignments clearly. Employees often get incomplete information or conflicting messages about what they are expected to accomplish.

When a work assignment is imparted, create an atmosphere that fosters employee questions. Employees might be embarrassed to ask questions because they might fear they would appear incompetent. Provide the option to ask further questions in various venues, and of various participants. Let employees know that you value them and that you are providing them with an assignment because you truly believe that they will be able to accomplish the task with excellence. Take a risk and give the assigned person full responsibility for the successful execution of the assignment. An effective organization is built of employees who want to do their assignments and take on more responsibility.

Some organizations have discovered ways to demonstrate their appreciation and concern for employees, such as management staff spending several days per year working on the "line" or "floor." Few things motivate and impress employees more than seeing their manager pitching in when the pressure is on. Extra days or afternoons off, which are not counted against their paid leave, have been successful as well. Check with a human resources specialist before awarding any noncompensatory/benefit-type rewards. Run out of new ideas? Ask your employees what would be meaningful to them, and ask them annually. No one knows better than the employee what will incentivise, reward, or motivate them.

Employees work harder and more effectively in a humanized environment that treats employees as individuals working in a team environment. Career ladders are important to motivate employees toward self-improvement. They can be created to offer technical professionals the opportunity to transition from functional specialists to managers. In engineering, classical career ladders (e.g., new titles, staff-management responsibilities) can be difficult to construct. Selection for assignment by project complexity and importance might well replace the classical ladder. It is recommended that opportunities for advancement be made whenever possible. It is difficult for employees to be satisfied working in cubicles when upper management are not, especially if the differences are excessive. While most employees understand the financial implications of workspace and the need

for managers to have space allowing confidentiality, it is important to provide quiet, private workspaces for cubicle-bound employees.

Financial rewards definitely motivate employees. Most staff are familiar with what their peers are being paid and with comparable benefit packages elsewhere. It is absurd to think that an employee who can, for example, calculate the increase in the height of the Empire State Building that occurs when the moon is directly overhead, will not know how his colleague is compensated in a competitor organization. Managers need to be aware of salary and benefit-package surveys, and they need to be prepared to impart the information to employees and to senior management.

Organizations employing technical professionals face a common dilemma: How to establish reward systems and work environments that are both stimulating to the professional and productive for the organization. Standard management strategies for motivating, rewarding, and leading nontechnical employees frequently fail to work for those who are involved in research, development, and engineering, thus resulting in performances that are suboptimal for the individual and the organization. Yet if financial compensation is not available (for good reason), staff might be receptive to creative motivational alternatives.

Performance Management

Performance management requires the participation of both parties to the process; the manager/supervisor and the employee. It can be defined as the constant communication between the parties of status of work, needed revisions or changes, and reflection on performance to improve future efforts. Performance management is not solely the annual review. The effectiveness of the performance-management process suffers from long periods where there is no communication. The best processes provide ongoing, almost immediate review and feedback, timely corrections, flexibility, and training focusing on addressing recognized weaknesses. Immediate, ongoing performance management can take the "financial" aspect out of the performance-management process except for, perhaps, the scheduled annual and biannual review. Unfortunately, it is recognized that managers and employees alike can be uncomfortable and even defensive at annual reviews. Eliminating the financial aspect can allow both the manager and the employee to focus on the actual events that are occurring and on determination of the support that the employee may need in order to learn, improve, and progress.

The basis of the performance-management process includes clear definition of the job, expectations, ways in which performance will be measured, and the process that will be used. Managers and employees alike can become truly frustrated by constant changes in the process, obfuscation of expectations, inclusion of unclear or poorly defined expectations, or inability to measure performance. While some flexibility in the process is necessary, organizations that have haphazard, poorly coordinated performance-management processes or that lack senior support for same usually contribute to problems that develop between managers and employees. Organizations that do not clearly define the manager/employee relationship and that do not promote immediate, ongoing feedback can find themselves with ineffective managers and stagnant or lost employees.

The Performance Review

If the performance-management process is immediate and ongoing, the performance review need not dwell on specific events that occur around the date of the review. Rather, it can focus on broader issues such as salary, promotion, training, discipline, and termination. While many engineering managers would like to avoid discussion of discipline and termination, sometimes the financial aspects of the organization or a specific project require a reduction in human resources that may well include good, productive engineers. The performance review, if performed correctly and consistently, can provide one measurement of value and contribution to the success of the organization. Unfortunately, if the process is flawed (e.g., if expectations are inflated beyond reason, or if measurability is impossible), performed inconsistently, or lacking in objectivity, the measurement is useless. There is no wonder that employees become defensive, elect to leave employment there, or are so disheartened that it affects productivity to the extent that no one throughout the entire organization meets, for example, a performance expectation.

Performance Review Criteria

Criteria should be based on the actual job—the duties and responsibilities of the position. Nothing can be seen as more ridiculous to an employee than a performance evaluation based on criteria that are outside their control. Inclusion of such criteria outside the control of the professional often causes employees to wonder whether senior management or their direct supervisor actually knows (or cares to know) what the contribution of the particular professional actually is.

One method of classifying criteria is measurable and behavioral. Measurable criteria can be evaluated in terms of quantitative and qualitative terms. For example, all projects were completed on time and within budget; 20 client visits were performed out of 20 expected; profitability rose 5%, reaching the set goal; or projects were completed in a manner that is acceptable to the organization. Behavioral criteria are actions that can be observed or described (e.g., an employee fails to get along with others at times, always contributes to creative processes, or consistently conveys the organization's message).

One simple way to improve the effectiveness and utility of performance reviews is to train supervisors and employees in the process. Training in giving and receiving constructive criticism can improve not only the process, but also attitude. Training managers in ways to observe and interpret behavior or common factors that distort reviews can improve the value of the process. Unfortunately, organizations that place little emphasis on the performance-management process can be expected to place even less emphasis on training because the process itself is so confused.

It is important that the review include open dialogue; a monologue by the supervisor could be expected to ensure defensiveness and to promote misunderstanding. Documentation of performance and behavior should be a mainstay of the process. All too often the manager throws together uncharacteristic examples of both, at the last minute, in order to meet a perceived need for a performance review to occur, without implementing a process that includes immediate and ongoing performance management and documentation of same throughout the preceding year.

Discussion of the results, not necessarily ending in agreement or consensus, should occur. Objective review of these discussions and remaining differences can often result in identification of invalid criteria, trends in employee dissatisfaction or misunderstanding, or managers requiring assistance.

Development of an action plan to move forward for the next period should not only be developed but agreed upon. If a feature of an action plan cannot be agreed upon, it is best to address that detail immediately. This may require arbitration, mediation, or discussion with others. It is rare, in our experience, for employees to take a stand against a particular aspect of a performance-review action plan. When they do, often there is either something truly wrong with the feature, or the discussion has led them to misunderstand the nature of the plan. While performance review often has a negative connotation and promotes negative images to the employee, it can become an opportunity to promote team building, to enhance the opportunity to coach or mentor an employee, to motivate or to encourage an employee to improve their position, or to emphasize an employee's security and value to the organization.

Stress Management

Relax. Take a rest. Go fly a kite, or just calmly sit and watch the world go by. Easy to say, but often difficult to do—maybe even stress-producing. Stress exists in everyone's life, but not all stress is necessarily bad. What stresses one individual might not stress another. Managers might have their own stress, plus inherited stress of others. How stress manifests itself, how we react; and how we manage it can be different for each of us. For example, the opportunity to present the outcome and success of a team project to upper management might be an agonizing prospect for one employee, but an honor, a challenge, and great fun for another.

Our response to stress can take different forms:

- Physiological: Increased heart rate, muscle tension
- Behavioral: Talking faster, social isolation, decreased or increased productivity
- Cognitive: Negative thinking, unwanted recurrent thoughts, new ideas
- Emotional: Excitement, anxiety, depression

Stress can undermine our effectiveness. Agitation and short fuses discourage employees or colleagues to approach each other in an open, nondefensive manner. If you are stressed, others know it, and the effect cascades. Calm, controlled leadership can inspire calm, controlled employees. Ability to identify stressors, their effects, and methods to harness the energy that stress produces can make managers more effective. It would be ideal if we could eliminate all stressors, but that would be unrealistic in the complex world where we live and work. You can remove some stressors from your life—a process that, in and of itself, can prove stressful. Some people actually take comfort in knowing that they are stressed—they are in demand, or they consider the causes of their stress to be important. Any method that you find effective in approaching stress is acceptable as long as the stress does not negatively impact your life or those around you.

People are different; they want or need different things, they behave differently (even under the same circumstances) and may believe differently. Some people like to be around other people, while others prefer to be by themselves—going to a party is actually stressful for some. Some make decisions quickly, while others prefer to keep their options open, perhaps collecting more information before making a decision. Some enjoy working from checklists, laying things out in an orderly fashion and systematically accomplishing items one at a time. Others find their creativity stymied if they are forced to work under such requirements, and they find it humorous to infuriating that more time might be spent documenting the performance of activities than in actually performing them. Some are highly rational, logical, and orderly, while others are reflective and intuitive. Some go “by the book,” doing things consistently and predictably every time. Others seek creativity and innovation; they thrive on chaos and are bored by routine.

Experience shows that some personal styles are generally better suited to technical endeavors, scientific activities, and engineering. Certainly not all engineers are alike, but there are many similarities in personality traits that lead to similarities in managing stress. There are many personality-testing instruments available today. None comes close to measuring all the nuances of human personality, but they can help us to obtain a glimpse of who we are. The Meyers-Briggs Temperament Indicator is one of the best known. The full test consists of several hundred questions, although a shorter adaptation was developed by David Kiersey and Marilyn Bates. The tests examine the way people perceive the world and the way they determine what to do. Human reactions and perceptions have been analyzed, and the tests are designed to identify an individual's traits; i.e., general personality styles. People often straddle more than one category, and categories can overlap. The tests' designers believe that it is important to pay attention to those personality elements (i.e., psychological preferences and needs) that have the most significance, while acknowledging the overlaps.

Both tests score along the same four scales below and are available on the Internet or through management consultants. Remember that the tests are not infallible but are merely indicators of personality and temperament. Test instruments can be fooled if not answered directly and truthfully. In addition, temperament on the day of the test can moderately affect results. The results can identify strengths and weaknesses in leadership as well as stressors that need to be mastered in order to be more productive and effective.

1. E/I = Extrovert/Introvert: This scale measures the ways in which use of perception and judgment is affected by yourself and those around you. The person who prefers to be with other people probably tests more E than I. The person who prefers his own inner world of ideas and reflection probably tests more I than E. Approximately 75% of the population tests with an E preference, and 25% with an I.
2. N/S = Intuition/Sensing: This scale measures the ways in which one gathers data for decision making. The person who believes that he is practical and fact-oriented probably tests S. The person who relies on unconscious perceptions, “gut” reactions or “hunches” probably tests N. Experts say that differences on this scale are the greatest source of miscommunication and misunderstanding of the four scales. The S person perceives through facts and believes that experience is the best teacher. The N person is concerned about what could be. He can be bothered by reality, and he prefers to speculate about possibilities. Engineers and scientists most often test out as N's. Approximately 75% of the population tests as S while 25% tests as N.
3. T/F = Thinking/Feeling: This scale measures the ways in which one chooses or decides how to make decisions. T type people are more comfortable with impersonal, objective judgments. F-type people are more comfortable with personal, value-driven judgments and often are put off by rules. Formal schooling tends to develop our T side, and engineers and scientists tend to score as T's. This is the only scale that is influenced by gender: 60% of women test as F, while 60% of men test as T.
4. J/P = Judging/Perceiving: This scale measures the ways that we respond to what is happening. Persons who test J generally prefer a great deal of closure with a significant need for things to be settled, including deadlines. P-type people prefer to keep their options open, often wishing to delay their judgments, including deadlines. The populations tests approximately 50% J and 50% P.

Stress-Management Techniques for Introvers: Find comfort in your inner peace. Recognize your strengths and knowledge. Draw on your strengths to increase communication and interaction with peers. Listen quietly to others' input. Take action when you are comfortable with the action. Remember that more high-technology professionals are introverts than extroverts.

Stress-Management Techniques for Extroverts: Use your inner focus to assess relevance of ideas before sharing them with others. Use that inner focus to assess appropriateness before speaking, and reflect before acting.

Stress-Management Techniques for Sensors: Focus on the bigger picture to prioritize the details, and proceed accordingly. Consider new solutions that would be appropriate to the problem at hand.

Stress-Management Techniques for Intuitives: Focus on relevant details, concrete realities, and the particular problem at hand. Consider existing solutions.

Stress-Management Techniques for Feelers: Recognize that some conflict is inevitable and that you are not going to be satisfied with the outcome of all situations. When comfortable, assert your own interests. Try to understand that you will never fully understand others and their situations.

Stress-Management Techniques for Perceivers: When you are comfortable and ready, make a decision, even if all information that you believe is important is not available. Build in a structure for obtaining the information that you need.

Stress-Management Techniques for Judgers: Consider significant information that is relevant to a decision. Recognize that organization is only a means to an end—the method for arriving at the decision. Evaluate, for relevance and completeness of work, your decisions that were made without all relevant information.

The goal is not to eliminate all stress. If you know your stressors, you can tackle them in a proactive manner and can create a more balanced, flexible approach to future stressors. Stress-management models can be helpful. Other helpful methods include relaxation training, cognitive restructuring, assertiveness training, vacations, and exercise. If you are experiencing a significantly increased level of stress that is resulting in a significantly decreased level of function, you might want to consult with a professional.

Interviewing

Match the applicant to the job, situation, and environment! Assuming that the organization is participatory and team-oriented, the purpose of an interview is to find the best person to supplement or replace a team member within a team that already has goals. Maintaining an emphasis on the goals of the team and ways in which an applicant might contribute or (fail to contribute) to attaining those goals can keep the interview process in the correct perspective. Interviewers essential try to gain sufficient information with which to forecast whether and how an applicant will work within the team. Forecasting is fraught with problems, and forecasting based on incorrect or incomplete information is even more problematic. Keeping the above in mind, some of the objectives of the interview process include:

- Fleshing out the details of data on the application
- Obtaining additional data that is not on the submission
- Probing the applicant to determine how he might respond in situations that are likely to occur within the team and its projects
- Monitoring and assessing the applicants' behavior (e.g., motivation, appearance, character, or forthrightness)

Common failures within the interview process include:

- The interviewer being unfamiliar with the actual needs of the specific job or team
- The interviewer being unprepared (e.g., untrained in the interview process; failing to have a structure for the interview; or failing to know and focus on the goals of the interview)
- Bias (e.g., conscious or unconscious application of interviewer biases or preferences toward the interviewee or the position)

- Unreasonable reliance on first impression or intuition
- Creating an interview environment that is not conducive to the task (e.g., noise, constant interruptions, or insufficient time allotted)
- Failure to listen (e.g., propensity to talk, leaving little time for the applicant to convey data).

The interviewer(s) can take some initial steps to properly prepare for interviews and to avoid, to the extent practicable, these problems. Interviewers should receive training in ways to conduct and analyze interviews and should remember that there are laws (e.g., Title VII of the Civil Rights Act) that prohibit discrimination. Interviewers should carefully review submissions prior to the interview as well as aspects of the specific job and environment into which the successful applicant may be inserted. It can help to develop, in advance, questions that can elicit new information about gaps or ambiguity in the submission; how the applicant has responded to challenges in the past; how they might approach a hypothetical problem-solving situation that could arise within the environment in which they will need to work, and work and personal work habits that might meld well or poorly within the current team.

Gathering of the interviewers, post-interview, to review, compare, and discuss information gathered is usually a good idea; new information and impressions can be shared among all interviewers; misinformation can be identified (both given by the interviewee and collected by the interviewer); and bias can be identified and resolved. It is important that the purpose of an interview (i.e., find the best hire to supplement or replace a team member within a team that already has goals) should be re-emphasized at this time.

Problem Employees

One of the most time-consuming and difficult situations that a manager can face is in having a problem employee. A problem employee can be a new hire who brings along “baggage” that slips through the interview process and probation period. A long-term employee can become a problem employee due to personal or other factors.

First, a manager should try to determine the extent and cause of the problem (e.g., tardiness, inability to meet deadlines, or undermining the authority and effectiveness of management). Second, a manager can examine whether the organization contributes in any way to the problem. Third, the manager should evaluate whether or not the situation can be remedied realistically and the resources that would be necessary to do so.

Replacing employees can be costly, especially when considerable resources have been expended in recruiting, time, and training. If the employee is receptive to discussing and addressing the problem, the situation can improve. If the employee is not receptive to discussing and addressing the problem, the problem could spread and undermine the morale and productivity of the entire staff.

When a manager suspects or is advised of a problem, the approach should be direct, discussed with all parties in confidence, and begin the documentation process. Always get all sides of the story, from the involved employee(s), from bystanders, or from others outside the organization. Be sensitive to the fact that all of these parties eventually might need to interact together again, and promote mutual respect where possible. Once the facts are known, confront the problem employee if it is appropriate. Never criticize an employee in front of other employees. Do not cause someone to “lose face.” Take the sting out of criticism by focusing the discussion on the task, and not on the person.

Some managers find it helpful to allow the problem employee to develop a remedial program that can be followed, to address the problem and to set milestones to meet to review progress. Unfortunately, it must be accepted that not all problems can be resolved, and that termination of problem employees might be best for all parties. The manager must be aware of, and must follow, the organization’s human resource policies relating to steps to follow under these circumstances. Most termination policies do not begin at the point of termination. Rather, they begin weeks or months earlier, to ensure that adequate attempts are made to rehabilitate the problem employee and that the organization’s liability is minimized. Hence, managers should seek counsel with, and the guidance of, human resources professionals as soon as they suspect that a problem exists.

Employment Laws and Regulations

All managers should have a basic understanding of the important elements of the employment-related laws and regulations. Human resource departments and attorneys specializing in employment law are your best resources when an action or issue arises. Equal-employment laws are enforced by a variety of federal agencies, including the Office of Civil Rights and the U.S. Department of Labor. The U.S. Department of Labor administers and enforces more than 180 federal laws. These mandates and regulations cover many workplace activities for about 10 million employers and 125 million employees. Following is a brief description of many of the applicable statutes, but it should not be considered complete or extensively detailed. It is intended to identify the major labor laws, not to offer a detailed explanation of them. Consult the statutes and regulations for details.

Wages & Hours: The Fair Labor Standards Act (FLSA) delineates standards for wages and overtime pay. The act is administered by the Wage and Hour Division of the Employment Standards Administration (ESA). It requires employers to pay covered employees who are not otherwise exempt at least the federal minimum wage, and overtime pay of one-and-one-half-times the regular rate of pay. The Wage and Hour Division also enforces the labor standards provisions of the Immigration and Nationality Act that apply to aliens who are authorized to work in the U.S. under certain non-immigrant visa programs.

Workplace Safety & Health: The Occupational Safety and Health Act is administered by the Occupational Safety and Health Administration (OSHA). Safety and health conditions in most private industries are regulated by OSHA or OSHA-approved state systems. Employers have a general duty under the OSH Act to provide work and a workplace that is free from recognized, serious hazards. OSHA enforces this statute through workplace inspections and investigations.

Employee Protection: Most labor and public-safety laws, and many environmental laws, mandate whistleblower protections for employees who complain about violations of the law by their employers. Remedies can include job reinstatement and payment of back wages. OSHA enforces the whistleblower protections in most laws.

Uniformed Services Employment and Reemployment Rights Act: Certain persons who serve in the armed forces have a right to re-employment with the employer they were with when they entered service. This includes those called up from the Reserves or National Guard. These rights are administered by the Veterans’ Employment and Training Service (VETS).

Employee Polygraph Protection Act: This law bars most employers from using lie detectors on employees, except under limited circumstances. It is administered by the Wage and Hour Division.

Garnishment of Wages: Garnishment of employee wages by employers is regulated under the Consumer Credit Protection Act, which is administered by the Wage and Hour Division.

The Family and Medical Leave Act: Administered by the Wage and Hour Division, the law requires employers of 50 or more employees to give up to 12 weeks of unpaid, job-protected leave to eligible employees for the birth or adoption of a child or for the serious illness of the employee or a spouse, child, or parent.

A number of federal laws and regulations prohibit discrimination on the basis of race, color, religion, sex, or national origin, both by the federal government itself and by organizations receiving various types of federal financial assistance or government contracts. These include:

- Title VI and Title VII of the Civil Rights Act of 1964, as amended in 1972 and 1991
- The Equal Pay Act of 1963
- The Age Discrimination in Employment Act of 1967 (Public Law (PL) 90-202) (applies only to people at least 40 years of age; for participants in programs or activities receiving federal financial assistance, the relevant law is the Age Discrimination Act (ADA) of 1975, which applies to people of all ages)
- The Americans with Disabilities Act of 1990 (P.L. 101-336)
- Section 503 and 504 of the Rehabilitation Act of 1973, as amended

The EEOC’s regulations are published annually in Title 29 of the Code of Federal Regulations (CFR). The CFR is available online through the U.S. Government Printing Office. (<http://www.gpoaccess.gov/cfr/index.html>)

Quality

Thomas M. Judd

Director, Quality Assessment, Improvement and Reporting,
 Kaiser Permanente Georgia Region
 Atlanta, GA

This chapter on quality introduces the reader to the main concepts of clinical quality improvement (QI) and ways in which they can be applied to clinical engineering activities. Clinical engineers (CEs) need to understand and to apply basic quality principles in their work, such as having the right people doing the right thing at the right time (Deming,1986), and they need to learn how their health technology planning and management work can best contribute to improved quality of care.

Techniques are presented for improving the quality of health care delivery and technology management practice, in particular. Quality can be measured and improved through:

- Appropriate quality culture and QI infrastructure
- Prioritized QI initiatives based on impact (disease burden), improvability (quantified gap between current and evidence-based best practice), and inclusiveness (broad relevance and reach)
- Appropriate QI indicators and tools
- Performance feedback and other methods
- Using best science for care (evidence-based medicine) and CE practices

Some applications of these techniques include medical equipment quality-assurance and improvement programs, regulatory-compliance programs, customer-satisfaction surveys, patient safety, and improving cost-effective use of technology resources. These applications will be demonstrated through several case studies.

Quality Culture and Infrastructure

Business Principles

- Leadership implies establishing unity of purpose, direction, and the internal environment of an organization, creating the environment in which people can become fully involved in achieving organizational objectives.
- Factual approach to decision making: Effective decisions are based on the logical or intuitive analysis of data and information. "You can't manage what you can't measure."
- Involvement of people: People at all levels are the essence of an organization, and their full involvement enables their abilities to be used for the organization's benefit.
- Customer focus means knowing whom your organization serves, understanding their current and future needs and requirements, striving to exceed customer expectations, and acknowledging other stakeholders.
- Process approach: Desired results are achieved more efficiently when related resources and activities are managed as a process. Process-performance examples include accuracy, timeliness, dependability, cycle time/throughput, staff effectiveness and efficiency, utilization of technologies, and cost reduction.
- "Systems approach to management" implies identifying, understanding, and managing a system of interrelated processes for a given objective that contributes to the effectiveness and efficiency of an organization.
- Continuous improvement is a permanent objective of the organization.

- Mutually beneficial supplier relationships enhance the ability of the organization and its suppliers to create value.

Health Care Delivery Principles

- Preventive activities are stressed. Prevention or early identification of harmful events extends resource life.
- Reduce inappropriate variation in diagnoses and treatment. Find the best science and implement it; avoid overuse and underuse. Activities should have compelling evidence, also known as "doing the right thing."
- Deliver care in a patient-centered manner. Provide all the information they need in order to participate in decisions.
- Those who know how to deliver care (or service) must lead the improvement process.
- QI is most efficiently done through multidisciplinary teams.
- Measure and give feedback, and intervene to improve. Reduce waste in all forms.
- Good medicine is good business, characterized by physicians ("the right people") making health care decisions and "doing the right thing" for patients. Leadership in their marketplace for "quality of care, service, and affordability" is a core value for health care organizations and increasingly is a key business strategy and goal.
- Quality of care is a measure or indicator of the degree to which health care is expected to increase the likelihood of desired health outcomes and to which it is consistent with the standards of health care (United States National Institutes of Health).
- Quality Indicators for an integrated health care delivery system:

<ul style="list-style-type: none"> ● Population health ● Episode characteristics ● Episode prevention 	<ul style="list-style-type: none"> ● Community benefit ● Financial performance ● Quality of care 	<ul style="list-style-type: none"> ● Satisfaction ● Efficiency ● Education 	<ul style="list-style-type: none"> ● Research ● Capacity
--	---	---	--

- *Health technologies (HT) impact on quality of care:* The concept is based on the premise that effective delivery of quality health care services depends on the availability and proper management of appropriate resources. These resources are primarily pharmaceuticals, human resources, medical devices, and facilities.
- *Essential Health Technology Package (EHTP):* The link between HT resources and the delivery of quality care is achieved by identifying all HTs needed to provide well-delimited promotive, preventive, and curative health interventions (Heimann et al., 2003).

Quality Improvement Priorities and Infrastructure Model

The strategic goals in 2002 in the health care organization that this author represents (Kaiser Permanente [KP]) were to have profitable growth, to hold or increase market-leading quality of care and service performance, and to improve cost position with competitors (Judd et al., 2003). KP pursued these goals through its physicians and employees; improving the work environment is key to success and is another organizational goal. Care and service (care experience) quality priorities in 2002 included focused objectives in disease-state management,

patient safety, continuity and coordination of care, and national report-card-quality measures; and maintaining high national-accreditation status for the services that KP delivers.

The health care organization annually sets quality priorities and evaluates the performance of the QI program to assist in meeting strategic targets, to ensure compliance with all appropriate regulatory and accreditation requirements, and to meet business imperatives (e.g., risk, contractual, and financial). Goals, initiatives, structure, and/or responsibilities are changed or aligned to ensure an effective, ongoing program. Responsible managers and physicians evaluate performance against targets, identify opportunities to improve (and constraints against that improvement), and submit evaluations and proposed work plans to their sponsoring operations leaders. Various committees and work teams (the quality infrastructure) evaluate their efforts in their areas of expertise and submit evaluations and proposed work plans to the organization's key quality committee.

The KP's key quality committee oversees performance against stated priority goals and quality themes throughout the year through regular reports and updates, and it reviews progress toward goals annually. There are three levels of review, with increasing intensity—quality monitoring, QI projects (QIPs), and QI activities (QIAs). Quality monitoring is the systematic measurement of key processes and outcomes used to ensure consistent performance and to detect opportunities. QIPs use a template to describe activities relating to the systematic improvement of a measured process or outcome and may be clinical- or service-oriented. QIAs are long standing QIPs that will meet the rigor of scrutiny for accreditation. A quality theme is an area of broad organizational interest that cuts across many structural areas. It represents an issue that should be a consideration of some, if not all, QIPs. In 2002 our quality themes were patient safety, continuity and coordination of care, member care experience, elder care, health-services research, and issues of clear community interest (e.g., minority and women's health). Quality themes and QIAs are our clearest organizational quality priorities and are displayed in the Quality Projects Matrix, a tool to assist the key quality committee in its QI program oversight.

Throughout the year, new action plans are concurrently incorporated into established work plans in response to identified issues and recommendations received from internal and external sources. Committees in our quality structure document these new plans in committee minutes. At the end of each year, action plans are evaluated, and actions that are not completed are rolled forward, as appropriate, to the following year.

Quality Improvement in Health Technology Management

Historically in clinical engineering, this has meant conducting those QI activities that keep desirable outcomes with use of medical equipment occurring and preventing the occurrence of undesirable outcomes. A QI process was developed by the U.S. hospital-accrediting body, the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), in order to provide a patient care environment that is continually safer and that provides higher-quality patient outcomes. A typical array of QI indicators that may be used in HTM are in Table 54-1. This is typically an ongoing, hospital-wide process that is the responsibility of the entire staff at all levels. It empowers employees to make changes that improve care and service outcomes. It is a 10-step method that allows assessment and improvement of performance, through structure, process analysis, and outcome measurement. Its application is noted in the first case study below.

Case Studies

A Clinical Engineering Project to Enhance IPM Services, Dennis Autio, OSU. (See Chapter 50.)

The following example reviews ways in which some of these principles can be integrated into a complex process in CE to monitor and improve scheduled inspections and preventive maintenance (IPM) services.

Problem

The current monthly IPMs completion rate is 52%. Some IPMs take several months to complete. Some IPMs are not completed. IPMs included a variety of tasks, including electrical-safety inspections, operation checks, and periodic maintenance procedures. Procedures are not well-documented.

Goals

Identify timetable to complete monthly IPM services. Identify critical equipment to be included in this program. Deploy resources proactively to prioritize and complete IPMs in a timely manner.

Project team

All staff members participate in this project.

Initial Assessment

The project team reviewed the scheduled IPMs for the past two years and identified several trends and patterns:

- All IPM services are treated the same; there is no prioritizing of services based on equipment criticality.
- There is no proactive process to distribute IPM workload.
- The initial indicator identifies only the number of IPM services completed by the end of the month.
- There is no process to help the staff to assign, prioritize, and close out scheduled IPMs.

Table 54-1 Clinical engineering quality indicators.

Inspection and preventive maintenance	Repair
Type/number of devices scheduled for service	Down time (up time)
Type/number devices inspected	Specific equipment failure
Type/number of devices that failed an inspection	Number of repairs
Type/number: on-demand service	Average time per repair
Type/number found with physical damage	Down time due to repairs
Type/number of no problem found	Repair turnaround time
Type/number serviced more than once in 7 days	Response time for repairs
Type/number involved in incident	Repeat repairs
Type/number requiring abnormal labor or parts	Repairs delayed due to parts orders
Inspections failed	Down time associated with parts orders
No inspection-equipment not located or in use	Mean time to repair
Users	Miscellaneous complaints
User-related problems	Incident investigations
Percentage of user errors associated with high-risk devices	Equipment recalls
Number of user errors	
Number of repairs caused by user misuse or abuse	
Frequency of repairs by user errors	
Frequency of user errors on same shift or same unit	

Phase 1 Action Plan

- Identify the current process with the same indicator. It is noted that no threshold was determined. Additional information and time is needed in order to define a proper solution.
- Review equipment management program to standardize equipment function, physical risk, and maintenance requirements. Rate equipment as high or medium risk, based on standardized risk-assessment criteria, the first step toward standardizing the program.
- Verify that appropriate IPMs are scheduled, define the specific procedures to be used, identify estimated time to complete, and provide an opportunity to project specific resource requirements for each month.
- Provide staff training on the new risk-assessment process and ways in which IPMs are processed.

Second Assessment

Once the first phase was completed, the projected IPM schedule for the year was reviewed. With a standardized database, monthly workload projections could be determined based on risk category. IPM schedules will need to be modified to better distribute workload. The indicators need to be revised, and appropriate thresholds need to be developed based on risk assessment. Proactive assignment to staff and monitoring of IPM status are required.

Phase 2 Action Plan

- After assessing the existing IPM schedules from an equipment category perspective, these inspections are distributed equally throughout the year. Peak workloads that would require significant resources to be allocated for only IPMs, such as anesthesia machines, were identified throughout the year. In this case, these IPMs were scheduled quarterly, all of them on the same month, thus requiring a significant amount of staff time to complete. By doing one third of these each month, the monthly workload and allocation of resources could be better managed while still providing quarterly inspections.
- Program indicators with thresholds were determined for high- and medium-risk equipment categories. All of high-risk equipment and 80% of medium-risk equipment were to be completed within four weeks. Indicator data are posted at the beginning of each week, identifying the number of IPMs completed during the last week (per risk category). Weekly completion goals were established at 25% of the scheduled high-risk equipment and 20% of the scheduled medium-risk equipment.
- IPMs are no longer assigned by management but selected proactively by the staff at the beginning of the month. Staff develops a proactive plan to schedule this work to be completed weekly.
- This provided opportunities for the staff to meet and review this process, make observations, and recommend future actions.

Third Assessment

After the second phase, the staff felt that they had a better understanding of what was required, and they were provided with tools to monitor this task. Additional procedures were needed to define the way to close scheduled IPMs if they were not completed during the four-week interval. Monthly review meetings provided times to assess the services provided and to identify opportunities for improvement.

Phase 3 Action Plan

- Define procedure to close out an IPM at the end of the month. High-risk equipment had to be completed. Medium-risk equipment could be canceled if there were no equipment repairs within the past three months and the last scheduled IPM was completed, or if the equipment could not be located.
- Continue to use the program indicators and thresholds monitor performance on a weekly basis.
- Quick monthly meetings were held to review the IPM indicators for the past month, identify any trends or patterns, and review the IPM scheduled for the next month.

Process Review

- This process took over a year to implement. When it was completed, there was a defined process to manage IPMs within the department, and all staff were trained as to its use.
- Workload was better distributed throughout the year.
- Standardized procedures were identified, defining what was to be done and how long it would take to perform.
- Workload data were identified proactively and distributed by staff for completion.
- Many opportunities for QI were identified based on defining the services provided and by reviewing the data collected, resulting in improved quality, productivity, and timeliness of service.

Novamed’s QI-Focused Approach (Painter, 1999)

- Keep it simple, using only two or three indicators.
- Differentiate between quality and performance measurements, such as speed of resolution of problem versus number of inspections performed. Be consistent in measurement.
- Communicate the process to everyone, including the administrator, the appropriate clinical staff, and your own staff.
- Publish results in the work area, and review them in meetings.
- Put a committee of senior CE department staff together to review data and report results. Use your internal committee to evaluate data frequently enough to make a difference and to make your follow-up steps actionable (e.g., review monthly, report every six months).
- Expect improvement. Change your practices to improve. Look for steady and incremental changes, not major changes. Change the system, and not the people, to accomplish improvement. The people will follow.
- If indicator is not valid (e.g., not as good a measure of quality as you would like), change indicators.
- Never stop trying to improve. Keep changing the system to get better results.
- Make this process easy, and it will work. Make it complicated, and it will fail.

Mediq PRN’s QA-Focused Approach (Wang, 1999)

This program is designed to provide safe, effective rental medical equipment to customers. All equipment complies with or exceeds JCAHO, United States Food and Drug Administration (FDA), and most original equipment manufacturer (OEM) recommendations. There are five program components, as follows:

Equipment Acquisition

- All equipment is approved for safety and efficacy through FDA through clinical studies.
- It is virtually all tested and/or listed by Underwriters Laboratories (UL), ECRI, and Canadian Standards Association (CSA). (See Chapter 118.)
- Equipment acquisition is based mostly on customer demand and return-on-investment considerations.
- Pre-purchase testing and evaluation is performed on more critical equipment, and there are factory visits for equipment purchased in large quantities.

Inspection and Maintenance

- Categories include: Safety and performance inspection (at delivery or equipment transfer); preventive maintenance (according to established schedules); and reconditioning (extensive replacement of critical parts after thousands of hours of use).
- The inspection and maintenance schedule is automated based on OEM recommendations, risk analysis, and experience.
- Inspection, maintenance, and repair procedures are modeled after ECRI’s IPM system using OEM’s recommended checks (ECRI, 1979).
- The service-records archiving system accepts daily service reports and has data stored on write once read many (WORM) optical disks for legal purposes.
- Test equipment calibration is conducted at least annually.

Quality Monitoring

- For service center (i.e., central location) inspections, separate staff inspects equipment on scheduled and random bases.
- At branch (i.e., remote) locations, central staff inspects twice annually with reports to senior management.

- Unsatisfactory equipment transfer reports allow feedback between branches, and provides with central management oversight.
- Overdue inspection reports are provided monthly.
- Customer complaints are aggregated centrally, with branch follow-up, and finally are closed centrally.
- Each technician’s service reports are reviewed for accuracy and completeness through service-data audits.
- A sample of each technician’s service report data is compared with the computer system to ensure accuracy and completeness through service data entry audits.

Regulatory Compliance

- Medical device recall information is collected and analyzed, and appropriate follow-up is conducted.
- Medical device tracking reports acquisition of tracked devices to OEM.
- Device-incident reporting includes investigation of every equipment-related death or serious injury.
- Upcoming regulations are continually watched.
- OSHA regulations compliance is ensured for blood-borne pathogens and hazardous chemicals.

Staff Management and Quality Improvement

- Staff qualifications and training includes clear requirements for background, initial, and ongoing training.
- Customer surveys are conducted for external and internal customers.
- The QA program is being revised constantly as new science of HTM emerges.

Service-Quality Improvement

Overview

Health care organizations should recognize that many sources of customer-related information exist and should establish processes to gather, analyze, utilize, and deploy this information. The organization should identify sources of customer and end-user information in written and oral forms from internal and external sources. Customer information might include feedback on all aspects of product, customer requirements and contract information, market needs, and information related to competition. Sources of information on customer satisfaction might include customer complaints, direct communication with customers, questionnaires and surveys, focus groups, reports from consumer organizations, and reports in various media.

The clinical engineer strives to deliver quality service. In order to know and to improve the level of the service provided, and to understand the expectations and the perceptions of the customer of that service, the CE must understand and use various sources of information on service quality or customer satisfaction. Survey instruments are an effective way of gaining this information. By studying other surveys, the CE can create a customized survey tool to measure customer satisfaction for a particular organization.

Measurement of service quality typically involves the following considerations:

- Asking customers for feedback on their care experience
- Focusing on a few satisfaction measures, and understanding key drivers of service quality
- Developing a survey based on customer needs and changing the surveys when the customer’s needs change
- Understanding that how the survey is delivered matters
- Repeating surveys to make the results actionable; trending results; and intervening to improve
- Inviting comments with specifics related to individual customer experiences

Survey Examples

Several forms of satisfaction surveys are shown for health care and HTM customer satisfaction with key features as noted in Table 54-2.

Table 54-2 Health care and health care technology management customer-satisfaction survey elements

<i>Common features</i>	<i>CAHPS* Managed Care Member Survey (NCQA, 2003)</i>	<i>CE Internal Customer Satisfaction (John Dempsey Hospital, 1999)</i>	<i>Hospital External Service Provider Survey (Novamed, 1999)</i>	<i>OEM Customer Satisfaction (GE Medical Systems; Varian Oncology Systems)</i>
Timeliness to start	Getting care quickly	Response time to arrive, prioritize services	Response time to arrive	Response time to arrive, prioritize services
Timeliness to finish	Getting needed care	Response time to complete	Response time to complete	Response time to complete
Communicate results	How well doctors communicate	Service provider communicated results		Service-provider communicated results
How service provided	Customer service	Service provider demeanor		Service-provider demeanor
Staff assistance	Courteous and helpful office staff	Service demeanor by support staff		Support staff ease of contact, style, parts availability
Business aspects	Claims processing		Equipment particulars	Sales support: style, responsiveness
Provider competence	Personal care provider rating	Technical competence	Technical competence	Technical competence
Results	Health care provider rating	Overall satisfaction	Overall satisfaction	Overall satisfaction
Management rating	Health plan rating	Management responsiveness and competence		Management responsiveness and competence
Other	Comments	Comments; Evaluator	Comments; Evaluator	Comments; Evaluator

*Consumer Assessment of Health Plan Satisfaction (CAHPS) used by the National Committee for Quality Assurance (NCQA).

Overview

Rosow and Grimes (2003) state in their *Nursing Administration Quarterly* article on "Technology's Implications for Health care Quality: A Clinical Engineering Perspective" the following views:

As hospitals are motivated by the need to reduce medical and medication errors, improve patient safety, create effective processes and cut operating costs, they look to and draw from quality management processes used by manufacturers and other industries. Four of the most popular processes used by health care institutions are the following:

1. ISO 9000 series quality management systems standards, first adopted in 1987 by the International Organization for Standardization (ISO). Originally intended as a quality systems tool for industry and manufacturers, the standards have been used by health care institutions to assess and improve their systems and processes.
2. Six Sigma, which is a rigorous, data-driven, decision making process. It utilizes a systematic five-phase, problem-solving process called DMAIC: Define, Measure, Analyze, Improve, and Control. DMAIC helps ensure that teams stay on track by establishing specific deliverables for each phase. Six Sigma is designed to eliminate deviations in operations. A company that adheres to Six Sigma standards will have 3.4 defects per 1 million opportunities, by using statistical models to measure performance in various categories. The key is to eliminate variation and give customers consistent, reliable service.
3. The Malcolm Baldrige National Quality Award employs seven categories that include leadership, strategic planning, customer and market focus, information and analysis, human resource focus, process management and business results. Managed by the National Institute of Standards and Technology (NIST), in cooperation with the private sector, the Baldrige award is given annually to businesses in the manufacturing, service, and small business sectors as well as to education and health care organizations. Education and health care categories were added in 1999. In 2002, there were 17 applicants in the health care category, the highest total so far.
4. Failure Mode Effect Analysis (FMEA), which incorporates a prospective assessment that identifies and improves steps in a process thereby reasonably ensuring a safe and clinically desirable outcome. In effect, FMEA is a systematic approach to identify and prevent product and process problems before they occur (Stamatis, 1995).

Our ability to achieve the level of quality necessary for the health care delivery system of the future requires the adoption and integration of technology into the health care process.

Recommended Clinical Engineering Involvement

Over the past decade, the medical device and information technology industries have made significant progress in designing and creating "smart" products and systems.

Figure 54-1 illustrates various levels of technology adoption and integration through the health care delivery process. Only by advancing more of the health care processes to Level 3 can we achieve the degree of quality that the system needs. Through adoption, standardization, and integration of technology, the quality, safety, availability, and cost of health care will improve.

In this era of rapid change and diffusion of medical and information technology, clinical engineers are essential members of multidisciplinary hospital teams. The clinical engineering perspective can be instrumental in identifying root causes and solutions with regard to patient safety and process improvement. An understanding of equipment and system design principles can produce insights that go beyond the standard behavior of the device or system in question. The ability to utilize best practices and quality-management systems allows clinical engineers to contribute to the improvement of management processes, efficiencies, and patient safety measures.

Linking Health Quality and Health Technology

Overview

Essential Health care Technology Package (EHTP) (see Chapter 45) is a new methodology and set of tools specifically developed to strengthen resource planning and technology management in health care (Heimann et al., 2002, 2003). As noted before, these resources predominantly include pharmaceuticals, human resources, medical devices, and facilities. The link between resources and the delivery of quality care is achieved by identifying all health technology (HT) resources that are needed in order to provide well-delineated health interventions. Health interventions are linked to the World Health Organization (WHO) International Classification of Diseases. This mapping between HTs and health interventions is based on internationally accepted and recognized clinical practices.

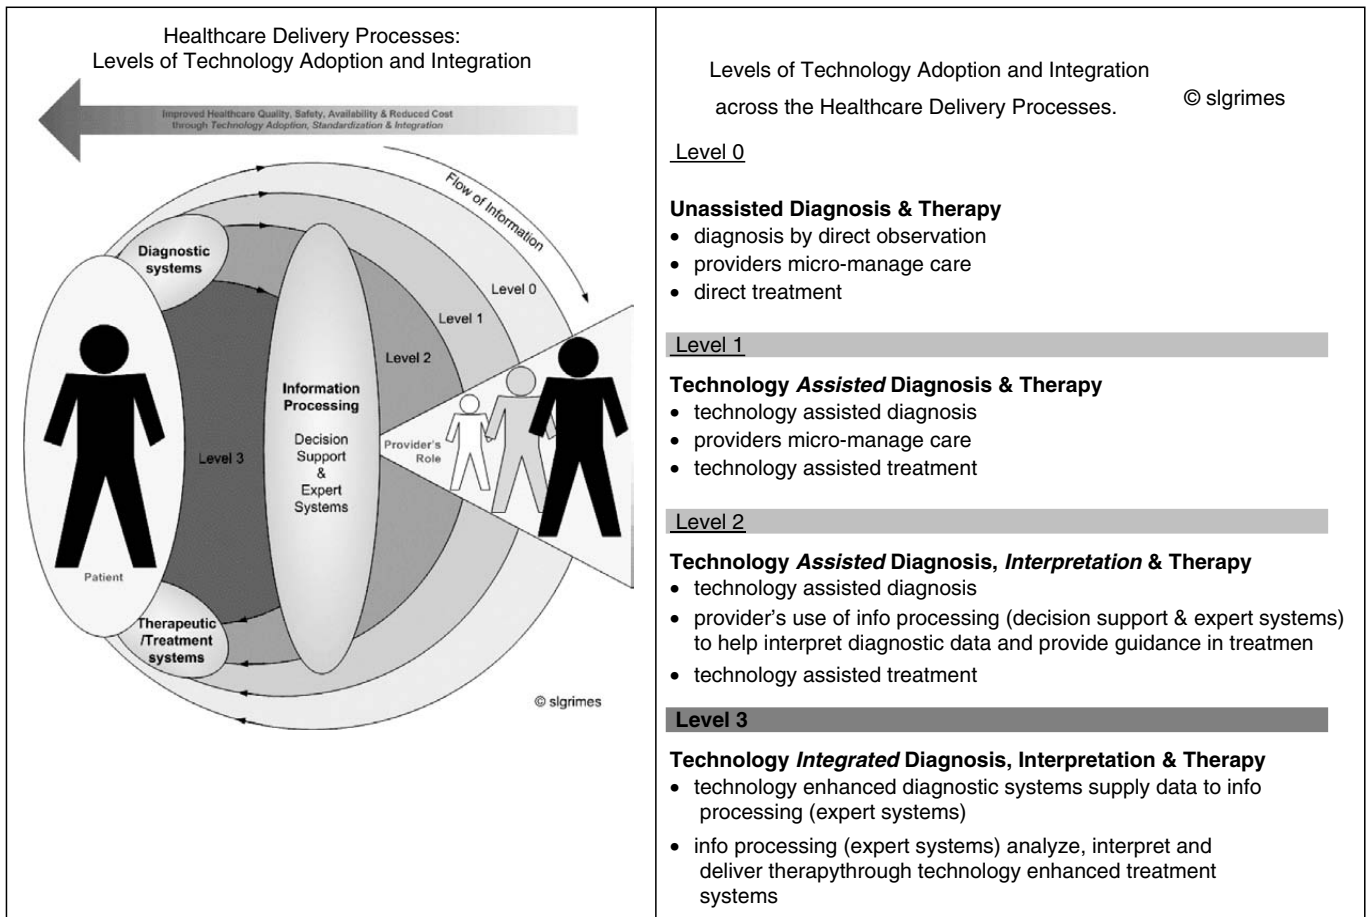

Figure 54-1 Recommended clinical engineering involvement in improvement of management processes, efficiencies, and patient safety measures.

Table 54-3 Key health conditions, clinical practice guidelines, and targeted medical device technologies linked

Key national health conditions	Primary level: Critical step(s) in CPGs for screening—treatment and medical device technology used	Secondary level: Critical step(s) in CPGs for screening—treatment and medical device technology used
Communicable diseases		Complications of condition diagnosed at primary care level
1. HIV/AIDS	Screening: Rapid HIV-1 tests via blood with lab equipment	Chest X-ray to rule out TB/pneumonia; Lab tests for TB and pneumonia if abnormal
2. Tuberculosis	Screening: Skin test, then sputum-slides-microscope if abnormal	Chest X-ray, lab tests to assess sputum and to grow TB cultures
3. Malaria	Screening: Rapid diagnostic tests, microscope-slides-blood	Lab tests to assess complications with liver and kidney
Key chronic diseases		
4. Hypertension	Screening: Assess BP with manometer-stethoscope; lab tests for cholesterol and kidney function	Cardiac status—ECG and chest X-ray; lab tests for cholesterol and kidney function (urine and creatinine)
5. Diabetes	Screening and tracking: Glucometer	Eyes—ophthalmoscope, kidneys—lab tests (urine and creatinine)
6. Asthma	Screening and tracking: Spirometer	Treat with aerosol chamber
Mother and infant health		
7. Prenatal care	Screening: Lab urine tests (or dipstick) to determine whether any infections; HIV-1 test	
8. Peri-partum care	Fetalscope	Fetalscope, forceps, oxygen delivery to mother
9. Cholera and diarrhea child health	Screening: Cholera packs; capability for IV resuscitation if diarrhea severe	IV therapy
10. Acute respiratory infections	Ears: Otoscope	Chest X-ray to rule out tuberculosis, asthma, malaria
Trauma		
11. Various	Suture materials	Orthopedic treatment: radiographic room (long bone X-rays)

From Heinemann et al. 2003.

Table 54-4 Assessment of optimal health care technology management for targeted health technologies

QI indicators by HTM category	QI indicators by title for targeted HTs	For 5 key conditions at each site, assess questions about HT “critical” items noted on Table 54-3
Planning (1-5)	<ol style="list-style-type: none"> 1. Percentage selected 2. Percentage with appropriate facility plan 3. Percentage with appropriate human resource (HR) Plan 4. Key Health Conditions, Clinical Practice Guidelines, and Targeted Medical Device Technologies Linked

One unique and powerful feature of EHTP is the integration of epidemiological profiles and recognized clinical practices such as evidence-based clinical practice guidelines (CPGs) or clinical pathways. If best clinical practice is known, then all HT resources to optimally deliver that intervention may be specified. This allows CE practitioners and health planners to potentially conduct optimal HT planning and management by meeting CPG requirements. Priority CPGs can be selected based on addressing the most significant disease burden for the population served and can be implemented in a manner that has been demonstrated to result in the highest quality of patient outcomes. (See Table 54-3).

Assessment of Optimal Health Care Technology Management for Targeted Health Technologies

As a result, a new technique has been developed to link medical equipment HTM techniques with their use in CPGs. The following case study illustrates this linkage. The technique is based on identifying targeted medical devices or HTs that are criti-

cal to successful implementation of the CPGs and their related interventions (see Table 54-4).

Conclusions

Case studies have demonstrated ways in which quality can be measured and improved through:

- Appropriate quality culture and QI infrastructure
- Prioritized QI initiatives based on impact (disease burden), improvability (quantified gap between current and evidence-based best practice), and inclusiveness (broad relevance and reach)
- Appropriate QI indicators and tools
- Performance feedback and other methods
- Using best science for care (evidence-based medicine) and CE practices

Applications of these techniques have shown models of medical equipment quality-assurance and -improvement programs, regulatory-compliance programs, customer-

satisfaction surveys, patient safety, and linkage of quality and technology for improving cost-effective use of technology resources.

Section V

Safety

Marvin Shepherd

DEVTEQ Consulting
Walnut Creek, CA

A medical device is just one component of a minisystem that delivers a clinical benefit to the patient. As device-related minisystems increase in number, the hazards associated with their use become more varied, and the clinical environment, more complex. Devices can become nonfunctional because of electromagnetic interference (EMI), or they can become fire-ignition sources for patients who are undergoing treatment in oxygen-enriched environments. Such medical device-related events require a clinical engineering investigation of the event and recommendations to prevent similar, future events. Because corrective recommendations frequently involve hospital professional staff and processes, they must be integrated into the total hospital safety program. The authors of the chapters in this section on safety address many of these issues and make recommendations for assuring a safe clinical environment.

Methodologies for making the clinical environment safer are described in the first four chapters. Patail (Patient Safety and the Clinical Engineer) gives the perspective of an experienced clinical engineer working within the National Center for Patient Safety (NCPS), showing that the clinical engineer is ideally suited a leadership role in promoting patient safety. Such systematic techniques as root cause analysis and failure mode and effects analysis, and tools such as process-flow diagrams, hazard-scoring matrices, and decision trees have enabled the NCPS to make measurable positive strides in a short time. Epstein and Harding (Risk Management), with their extensive experience in advising health care organizations on risk-management issues, present a comprehensive overview of this subject and present guidelines for adoption of effective techniques and programs. Vegoda and Abramson (Patient Safety Best Practices Model) bring their formidable expertise in information technology (IT) to bear on the patient safety issue as they outline a model system for patient safety best practices. Baretich (Hospital Safety Programs) provides an expanded view of hospital safety going beyond safety as applied only to medical devices. He describes the safety structure and requirements of a complete hospital safety program as required by the Joint Commission on Accreditation of Healthcare Organizations (JCAHO). The program encompasses the safety of staff, patients, and visitors from the various hazards in a health care environment. He emphasizes that, in order to be most effective, the safety-related aspects of clinical engineering practice must be integrated into this hospital-wide safety program.

Shepherd (Systems Approach to Medical Device Safety) identifies the five fundamental components of a medical device-related minisystem, a system that delivers at least one clinical benefit. In addition, he discusses the way these components can fail in such a manner as to prevent the clinical benefit from being delivered and may result, instead, in an injury or death. By means of this generic model, one can understand ways in which a patient might experience a particular hazard as well, and one can employ methodology to trace the fundamental causes of an injury back to the latent causes that were present in the minisystem. As the number and complexity of medical devices have increased, so have reports of interactions between various minisystems. Miodownik (Interactions between Medical Devices) explores some of the interactions among device-related minisystems when they are connected and operating simultaneously on or around a patient. Through case studies, he shows that the patient-selection criteria might not always identify those within a population who might be harmed by a diag-

nostic or therapeutic intervention. Device-device and device-patient interactions might directly result in an injury or a malperforming minisystem. His engineering analysis gives warning that clinical engineers must remain vigilant in order to detect unexpected minisystems interactions.

Cheng (Single-Use Injection Devices) details the safety aspects of needles and syringes, with an emphasis on their use and safety in developing countries. Recognizing that reuse of single-use injection devices is a leading cause of infection, Cheng recommends alternatives to this practice, such as auto-disable syringes, safety boxes, and the disposal of used sharps. He applies life cycle management concepts to injection devices to ensure safety in health-program planning and delivery.

Tan and Hinberg (Electromagnetic Interference with Medical Devices) provide a review of international EMI standards and an overview of EMI issues, including the effects of wireless telecommunication, wireless LAN, metal detectors, and article-surveillance equipment on medical devices is also included. Their chapter, developed from both the regulatory and the practical viewpoint, includes suggestions on managing the risks of EMI. Health care facilities are experiencing an increasingly hostile EMI environment. To ensure that a clinical environment is safe from EMI-provoked disturbances, clinical engineers must proactively manage the environment through detection, correction, and prevention of EMI. Paperman, David, and Hibbetts (Electromagnetic Interference in the Hospital) describe components of such a management program and present case studies from their own experiences to illustrate its value.

The role of the clinical engineer as medical device-safety officer or as independent forensic engineer requires specific skills in accident investigations. Dyro (Accident Investigation) provides a comprehensive overview of device-related accident investigations and describes the knowledge, skills, and investigative techniques that are necessary for a competent investigator. He emphasizes that the intended result of any investigation is to identify the latent (root) causes of an event and the minisystem modifications that are necessary to prevent similar events in the future. Accident investigators estimate that as many as 70% of all device-related, adverse events have some contribution from the human operator, often from the limitations of human abilities but frequently from inadequate human-factors-design considerations of the device manufacturer. Dyro discusses the fundamentals of human error and human factors design and their contributions to accidents. Clinical engineers, who should direct accident and incident investigations, must become familiar with the fundamentals of human error and human factors designs as they affect minisystem processes.

Finally, Ridgway (Electrical Safety in Perspective) describes the history of "microshock," a device-related hazard that appears to have been more imagined than real but nevertheless resulted in many unnecessary and expensive corrective actions in hospitals. In the early 1960s, small electrical currents that caused microshock were alleged to have killed thousands of hospital patients annually. Over the following twenty years, the concern for microshock emerged through both misinformation and a lack of information. Ridgway's insightful retrospective on microshock and the ensuing preoccupation with electrical safety describes the effort and resources that were expended and largely wasted in addressing this relatively minor hazard.

55

Patient Safety and the Clinical Engineer

Bryanne Patail

Biomedical Engineer, Department of Veteran's Affairs,
National Center for Patient Safety
Ann Arbor, MI

The clinical engineer (CE) is ideally suited for a leadership role in promoting patient safety. The safety of patients has gained widespread attention with reports of unusually high incidents of errors occurring in the administration of therapeutic and diagnostic interventions. Some of the reasons for the apparent compromising of patient safety explored in this chapter include financial constraints, fear of legal liability, and reluctance to admit to commission of errors. The Veterans Administration National Center for Patient Safety is in the vanguard of the patient safety movement as it attempts to change the culture of blame in its system of hospitals to the culture of patient safety. With proven systematic techniques such as the root-cause analysis and failure mode and effects analysis and the expertise of the CE, the NCPS has made measurable positive strides in a short time. Some of the tools, such as process-flow diagrams, hazard scoring matrices, and decision trees, used by the Center are described in this chapter.

The Clinical Engineer: Well-Suited for Patient Safety

The concept of patient safety is not new to CEs. In the past three decades since one of the first in-house clinical engineering departments was conceived and developed, safety has been the mission of such a department. A mission statement of a typical clinical engineering department is: "To assure a cost-effective, safe, quality environment for patients, employees, volunteers, visitors, and medical staff of the hospital, relative to patient care, diagnostic, therapeutic, and life-support medical devices, instruments, and systems." The American College of Clinical Engineering (ACCE) defines a *clinical engineer* as: "a professional who supports and advances patient care by applying engineering and managerial skills to health care technology." One of the missions of ACCE is "to promote safe and effective application of science and technology in patient care."

Clinical engineers are uniquely positioned to address patient safety issues for the following reasons:

By Law

The minute one claims to be an engineer, one is bound by fiduciary responsibility for the safety of the public. Webster's Dictionary defines *fiduciary* as "a person who stands in a special relation of trust, confidence, or responsibility in his/her obligation for public safety."

By Education

In any bona fide engineering school, core courses such as statics, dynamics, thermodynamics, mechanics of materials, physics and mathematics (calculus) prepare one to better understand the cause and effect relations of most problems and incidents. Engineers are known for their problem solving abilities. Most CEs hold undergraduate degrees in the calculus-based engineering discipline such as electrical engineering, mechanical engineering, or computer engineering, and a graduate degree in biomedical/clinical engineering. Some also hold a doctoral degree. In addition, many CEs are certified as certified clinical engineers (CCE).

By Experience

Over the past 30 years, CEs have participated in prospective approaches to ensure patient safety vis-à-vis technology assessment (T/A) projects. They have developed and published consensus standards (as members of AAMI) for almost all critical medical devices and systems, and many are now ANSI standards. Some CEs work as company consultants or collaborate with companies to conduct alpha or beta site testing of medical devices. Some spend enough on devices from one manufacturer to cultivate the influence to provide feedback and/or participate in the design of fault-tolerant medical devices and systems.

These activities are possible only if the CEs are also involved in retrospective assessments to ensure patient safety vis-à-vis incident investigations and since 1991 because of the Safe Medical Devices Act of 1990, CEs have been reporting all medical device vulnerabilities to the manufacturer and/or a central database (FDA MAUDE). The knowledge gained from reading investigations of incidents that occurred elsewhere allows CEs to plug back into the prospective risk-assessment process.

By Reputation

In addition to being credentialed with degrees and certification, CEs are well respected by their peers, appreciated by their co-workers, and trusted by their employers and customers. They usually have excellent track records in participating, educating, and consulting activities to improve patient safety. A high percentage of CEs participate in professional activities.

By Position in the Institution

Staff vs. Line?

Most staff positions protect the institution from exposure/liability; CEs work closely with the Legal Affairs department and lawyers' fiduciary responsibility is to protect their client the institution, which is sometimes in conflict with a CE's fiduciary responsibility to protect the public. Therein lies the problem. Solutions to this problem are presented later in this chapter.

On the other hand, a line position, or in some cases called operations, is responsible to produce the actual product (crank out the widgets). Someone in this position is expected to produce tangible, cost-saving, production support for the caring of the patients. Clinical engineering departments in most hospitals are relegated to repairing medical devices (mostly electronic devices). Therein lies another problem.

Leadership

Most reputable CEs also hold leadership positions in their hospitals. A CE is usually a department head, chairperson of a committee or committees, process owner, educator, or consultant.

Despite the unique position the CE might hold in a hospital or a health care organization to ensure safety, it has been estimated that close to 98,000 deaths occur annually in U.S. hospitals due to medical errors (Kohn et al., 2000). One is compelled to ask:

- What happened?
- Why did it happen?
- What are the root causes?
- What can we do to prevent it from happening again?

Factors Contributing to Medical Errors

There are many dynamics that played a part to reach to this point, and several are listed here.

Health Care Reimbursement

What Happened?

The changing landscape of health care reimbursement process in the U.S. played an important role in reaching the current state of affairs. Over three decades reimbursement went from a cost, plus a certain margin contractual fee-for-service arrangement, to a Diagnostic Related Groups (DRGs) capitated payment system, to HMOs and PPOs. The whole issue of treating health care as a business is the culture change that had devastating long-term impacts on patient safety. Strictly bottom-line orientation is the modus operandi of most hospital administrators (MBAs). Some nonprofit health care facilities are spinning off profit making arms and the COO of one of these service companies, LLC, told me "Patient safety initiatives are diametrically opposed to the objectives of this company." Quality of care and safety of patients took the back seat. The theme of hospitals these days is to do more with less. Is this the best way management can save money?

Why Did it Happen?

Many hospitals are struggling to stay afloat. When one is fighting to survive, one forgets the real mission of the hospital. Core values take the back seat and/or are missing.

What Are the Root Causes?

Our business schools must stop teaching MBA students the notion that “all is fair in love, war, and business.” Business leaders and CEOs must understand that they have an obligation to the community that provides them with the infrastructure, services, and other resources to conduct their businesses.

A CE, who is usually the department head, is bogged down with the daily tasks of managing the department, working with budgets, operations reports, meetings, and employees’ needs and demands. He or she does not have the time and resources to attend to the RCAs and technology/systems-related prospective and retrospective assessments. Therefore, in order to survive, many CEs manage to carve out their scope of responsibility to only repairable medical devices (mostly electronic devices) because the technicians in the department came from an electronics technician educational program or the ranks of electronic technicians.

What Can One Do About It?

Identify a need to reevaluate the core curriculum of MBAs. Teach them that the community provides a certain infrastructure, services, and other resources to allow them to conduct business in the community, and they have certain obligations to the community and the patients they serve. Core curricula of BMETs and CEs need to be reevaluated also. Teach and share with them the different kinds of failures/incidents/injuries that can occur in hospitals. Include not only the repairable medical devices arena, but also problems with the application of these devices, processes that have failed with nonrepairable devices, and the systems failures that have occurred so far. Teach them how to conduct root cause analysis and some of the successful forcing functions and other robust, fault-tolerant solutions that have been implemented to solve these problems. If the expectation is to have these people get involved in improving patient safety, consider some of the unsolved problems and how to conduct HFMEA™ to look at solutions and use new technologies and new processes to solve these problems. The CE’s job functions must meet the mission statement of his or her department.

Administrators Need to See Tangible Results

What Happened?

Myopic: Most administrators see tangible results of their investment in a few full time equivalents (FTEs) to repair medical devices as opposed to contracting out with the manufacturer for a maintenance program to save money. Did the administrators lose sight of the real mission of hospitals? CFOs literally control the direction of the business enterprise. The business people have done an excellent job to change the culture of the hospitals to think in terms of budgets and bottom lines. We are in the business culture. Although we are in the patient care business, patients are not number one—*business* is number one. However, the quality and safety people have not yet done an adequate job. If all the constituents in the hospital are properly represented, and their voices are heard equally, then there should not be a skewing of emphasis toward business.

Why Did it Happen?

Businesses complain about the spiraling cost of health care. The automotive industry estimated that health care cost accounts for \$300 of each car’s cost. So what? The American public demands the latest and best technology for its care. It is more glorious to have an MRI than an X-ray.

The ratio of Biomedical Equipment Technicians (BMETs) to CEs is 100 to 1. If you mention Biomed to a health care worker, the first thing that pops into his or her head is the repairman. Why? Because they see and meet the BMETs more often than they see and meet the CEs. Since the CE department is relegated to repairs, the CEs are also looked upon as repairmen.

Litigious Society

What happened?

Medical malpractice suits are on the rise. The U.S. public, in general, has become enamored with lawsuits and expects to become rich from the inconveniences and/or injuries sustained as a result of medical care. They perceive the physician, the hospital, and the medical device manufacturers as people with deep pockets and unlimited funds to pay for damages. The cover story in the June 9, 2003, issue of *Time* delineated how the soaring cost of malpractice insurance is driving some physicians out of certain regions, out of certain high-risk specialties, or out of medicine completely. And so the pattern continues.

Why did it happen?

Personal injury lawyers may be encouraged by the recent malpractice award of \$140 million in New York, chronicled in an article in *The New York Times* titled “New York Hospitals Fearing Malpractice Crisis” by Richard Perez-Pena.

What happened?

CONFIDENTIAL: CEs are not privy to all the patient safety incidents in a facility. Everything is confidential. The pattern repeats itself. In order to avoid litigations, physicians, nurses, health care workers, and hospitals treat all medical adverse events as confidential and do not discuss them with the front-line care providers. Many facilities take meticulous steps to avoid discovery of such events.

Why Did It Happen?

A punitive environment is a factor as well. Many surveys have shown that a high percentage of health care workers chose to work in health care to make a difference in curing the sick, healing the injured, and saving lives. They are dedicated, compassionate, intelligent, and motivated individuals. However, when a mistake is made and/or a patient is injured, the first question that most bosses ask is “Who did it?” Disciplinary action is often the first recourse. Mistakes or are not tolerated. Root causes are not identified, and eliminating an individual from a position seems to be the norm to solve problems.

What Are the Root Causes?

- Pharmacies conduct their own investigations on their own employees.
- Labs conduct their own investigations on their own employees.
- Radiology labs investigate their own employees.
- Operating rooms investigate their own employees.
- Nurses investigate their own employees.
- Cardiologists investigate their own employees.

What Can One Do About It?

Create a non-punitive environment, form multidisciplinary teams, invite subject-matter experts and process owners to the table, and discuss all patient safety issues. Make the discussion a learning experience, with the focus on preventing adverse events in your facility.

Solutions

Creating a Culture of Safety

Only by viewing the health care continuum as a system can truly meaningful improvements be made. A systems approach that emphasizes prevention, not punishment, can create patient safety success stories. Other high-risk businesses such as airlines and nuclear power plants have used this approach to accomplish safety goals. To make the prevention effort effective, we use methods of gathering and analyzing data from the field that allow the formation of the most accurate picture possible. People on the front line are usually in the best position to identify issues and solutions, so both root cause analysis teams and health care failure modes and effects analysis teams formulate solutions, test, and implement strategies, and measure outcomes in order to improve patient safety. Findings from the teams are shared with other facilities in the system. This is really at the core of what we mean “by building a culture of safety.” It is portrayed as the engine that propels the system toward the goal of maximum safety. This kind of cultural change does not happen overnight. It can only happen as a result of effort on everyone’s part to take a different approach to the way we look at things. We must constantly ask whether we can do things in a better, more efficient, and safer manner. We must never let “good enough” be good enough. We must be relentless in our pursuit of finding ways to improve our safety systems. We do not believe that people come to work to do a bad job or to make an error, but given the right set of circumstances any of us can make a mistake. We must force ourselves to look past the easy answer—that it was someone’s fault—to answer the tougher question of why the error occurred. There is seldom a single reason. Through understanding the real underlying causes of errors, we can better position ourselves to prevent future occurrences. Although the saying goes, “Experience is the best teacher,” it is one of the most expensive teachers as well. One of the best ways to reduce the expense is to take advantage of lessons present in close calls, where things almost go awry, but no harm is done. Establishing a culture of safety where people are able to report both adverse events and close calls without fear of punishment is the key to creating patient safety.

Challenges

Historically, accident prevention has not been a primary focus of medicine. Hospital systems were not engineered to be prevent or absorb errors; they changed reactively without being proactive. The hospital system had misguided reliance on faultless performance by health care professionals. Medical culture rewards perfection and punishes errors in a complex system not engineered for risk.

Unrealistic expectations discourage openness and honesty, and preclude learning from close calls. Mistakes may be made by capable, conscientious, and compassionate individuals trying to do the right things.

Tradition and values are also important; they were important to me. (that is the way I used to do it ... now you can do the same)

Human performance is fallible.

Create a Culture of Safety the VA Way

The following is a list of the steps that the Veterans Administration took to create a culture of safety:

- Assured a nonpunitive environment, except for intentional unsafe acts.
- Received a public commitment from health care leadership tied to the performance appraisal process of every health care facility director.

- Dedicated resources: 200 Patient Safety Managers (PSMs) and 22 Network Patient Safety Officers (NPSOs)
- Established Special Patient Safety Centers of Inquiry (SPSCIs)
- Provided Incentives for the VHA workforce to promote safety
- Directed safety efforts
- Created the National Center for Patient Safety
- Trained 1000 patient safety managers, patient safety officers, and others from 163 VA facilities and several private sector health care facilities over 3 years at a 3-day course on Patient Safety 101 and about 200 safety professionals at a 3-day course on Patient Safety 202.
- Developed and published the *VA Patient Safety Handbook*
- Created the Patient Safety Website at www.patientsafety.gov
- Developed tools such as RCA Software (SPOT) and the RCA database, HFMEA,TM and distributed them to every hospital CEO in the United States through the American Hospital Association
- Developed and distributed of cognitive aids
- Disseminated patient safety alerts and advisories
- Participated as consultants in the procurement and standardization of medical devices, products, and services
- Established a patient safety work group in the information systems (Office of Information) support team.

Since taking these actions, close-call reports in the VA have gone up by 900%, an indication that the blameless reporting system is working well.

Vehicles to Change the Culture

Root Cause Analysis (RCA)

Root cause analysis RCA is a process or technique used to identify the most fundamental reason or contributing causal factor as to why a problem occurred. It is a retrospective assessment, focused on finding vulnerabilities in the system and developing countermeasures. The process of RCA addresses four basic questions. 1. What happened? 2. Why did it happen? 3. What are the contributing causal factors? 4. What can we do to prevent it from happening again? The emphasis must be on developing effective countermeasures. The RCA team must be interdisciplinary in nature, involving experts from the front line who are closest to the safety process and who have the best ideas to solve the problem. RCA is a process that continually digs deeper by asking, “Why, why, why?” at each level of an event. It is a process that identifies changes that need to be made to systems, is as impartial as possible, and moves beyond blame. The RCA process must consider human factors and other factors, related processes, and systems, and analyze the underlying cause-and-effect relationships. Relevant literature must be reviewed during the process and internal consistency must be achieved. The RCA must identify risks and their potential contributions to safety errors, and must determine potential improvements in processes or systems. To be credible, an RCA must include the participation and support of the leadership of the organization and those most closely involved in the safety process and systems. Figure 55-1 is a flow diagram of an RCA team process.

The following are five rules of causation adapted for patient safety from a publication by David Marx on the NCPS website, www.patientsafety.gov:

Rule 1—Causal statements must clearly show the cause and effect relationship.

This is simplest of the rules. When describing why an event occurred, show the link between the root cause and the bad outcome, and each link should be clear to the RCA team and others. Focus on showing the link from the root cause to the undesirable patient outcome under investigation. Even a statement such as “resident was fatigued” is deficient without description of how and why this led to a close call or mistake. The bottom line is that the reader needs to understand the logic in linking the cause to the effect.

Rule 2—Negative adjectives such as poorly or inadequate are not used in causal statements.

As humans, we try to make each job we have as easy as possible; unfortunately, this human tendency works its way into the health care documentation process. We may shorten our findings by saying, “Maintenance manual was poorly written” when we really have a much more detailed explanation in mind. To force clear cause and effect descriptions and avoid inflammatory statements, do not use negative descriptors that are merely placeholders for more accurate, clear descriptions. Even words such as “carelessness” and “complacency” are bad choices, because they are broad, negative, judgments that do little to describe the actual conditions or behaviors that led to the mishap.

Rule 3—Each human error must have a preceding cause.

Most of our mishaps involve at least one human error. Unfortunately, the discovery that a human erred does little to aid the prevention process. Investigate to determine WHY the human error occurred. It can be a system-induced error, such as a step not included in the medical procedure or an at-risk behavior, such as doing task by memory, instead of with a checklist. For every human error in your causal chain, there must be a corresponding cause. The cause of the error, not the error itself, leads to productive prevention strategies.

Rule 4—Each procedural deviation must have a preceding cause.

Procedural violations are like errors, in that they are not directly manageable. Instead, we can manage the cause of the procedural violation. If a clinician is violating a procedure because it is a local norm, address the incentives that created the norm. If a technician is missing steps in a procedure because he is not aware of the formal checklist, improve education.

Rule 5—Failure to act is only causal when there was a preexisting duty to act.

We can all find scenarios in which our investigated mishap would not have occurred—but this is not the purpose of causal investigation. Instead, we need to find out why this mishap occurred in our system as it is designed. A doctor’s failure to prescribe a medication can only be causal if he is required to prescribe the medication initially. The duty to

perform may arise from standards and guidelines for practice or from other duties involving patient care.

Health Care Failure Mode and Effect Analysis (HFMEA)TM

To optimally meet the needs of a prospective risk assessment of health care processes, the National Center for Patient Safety (NCPS), with assistance from Tenet Health Systems of Dallas, Texas, developed a hybrid method, the Healthcare Failure Mode and Effects Analysis (HFMEA)TM, that combines concepts of FMEA from industry with the Hazard Analysis and Critical Control Point (HACCP) from food safety, as well as tools and concepts that are integral to the VA’s RCA process (Stalhandske et al., 2000).

The HFMEATM is a systematic approach to identify and prevent problems with products and processes before they occur. It is a prospective assessment that identifies and improves steps in a process, reasonably ensuring a safe and clinically-desirable outcome. HFMEA (streamlines the hazard analysis steps found in the traditional FMEA process by combining the detectability and criticality steps of the traditional FMEA into an algorithm presented as a decision tree. It also replaces calculation of the risk priority number (RPN) with a hazard score that is read directly from a Hazard Matrix Table developed by NCPS specifically for this purpose.

Prologue

During a midnight shift on an intensive care unit, a patient with an infectious disease was monitored by a physiological monitor while on a ventilator in an isolation room with an anteroom. While the patient was asleep, the assigned caregiver decided to help transfer her other patient, who was recovering well, back to a regular floor. While the caregiver was out of the isolation room, the first patient managed to extubate himself. No one heard the ventilator alarm or the physiological monitor alarm. When the caregiver came back to the room she immediately called a code and then attempted to resuscitate the patient, but the patient could not be revived.

What is the relevance of this story to proactive risk assessment and HFMEATM? A team examining this high-risk situation might have identified a number of vulnerabilities that could have been mitigated without the harm and tragedy that occurred. The following example depicts how this outcome may have been avoided by using the HFMEATM proactive risk-assessment model.

Basics of HFMEATM

HFMEATM is a five-step process that uses a multidisciplinary team to proactively evaluate a health care process. The team uses process-flow diagramming, a Hazard Scoring MatrixTM (Table 55-1), accompanying Severity Rating System (Table 55-2) and Probability Rating System (Table 55-3), and the HFMEATM Decision Tree (Figure 55-2) to identify and assess potential vulnerabilities. The HFMEATM Worksheet is used to record the team’s assessment, proposed actions, and outcome measures. HFMEATM includes testing to ensure that the system functions effectively and new vulnerabilities have not been introduced elsewhere in the system.

STEP 1 DEFINE the HFMEATM TOPIC

- Define the topic of the HFMEA along with a clear definition of the process to be studied. Think about narrowing the scope so that the review is manageable and the actions operationally sound (see Figure 55-4).

STEP 2 ASSEMBLE the TEAM

- The team should be multidisciplinary including subject matter expert(s) and an advisor (see Figure 55-4).

STEP 3 GRAPHICALLY DESCRIBE the PROCESS

- Develop and verify the flow diagram (this is a process vs. chronological diagram).
- Consecutively number each process step identified in the process flow diagram (see Figure 55-5).
- If the process is complex, identify the area of the process to focus on (i.e., take manageable bites).
- Identify all subprocesses under each block of this flow diagram. Letter these subprocesses consecutively under each block (i.e., Under block 1 as A, B, ..., D, under block 2 as A, B, ... E) (see Figure 55-5).
- Create a flow diagram composed of the subprocesses (see Figure 55-6).
- Transfer these to the HFMEATM Worksheet, Line 1 (see Figure 55-7).

A Helpful Hint: It is important that all process and subprocess steps be identified before proceeding.

STEP 4 CONDUCT a HAZARD ANALYSIS

- List all possible/potential failure modes under the subprocesses identified in Step 3. Transfer the failure modes to the HFMEATM Worksheet. (Hint: Failure modes include anything that could go wrong that would prevent the subprocess step from being carried out; they describe what could go wrong. For example: If logging onto a laptop computer is the process step, two possible failure modes are (1) not being able to log in and (2) delayed login. Use various methods including the NCPS triage/triggering questions, literature reviews, and brainstorming to identify potential failure modes.)

Root Cause Analysis (RCA) Team Process

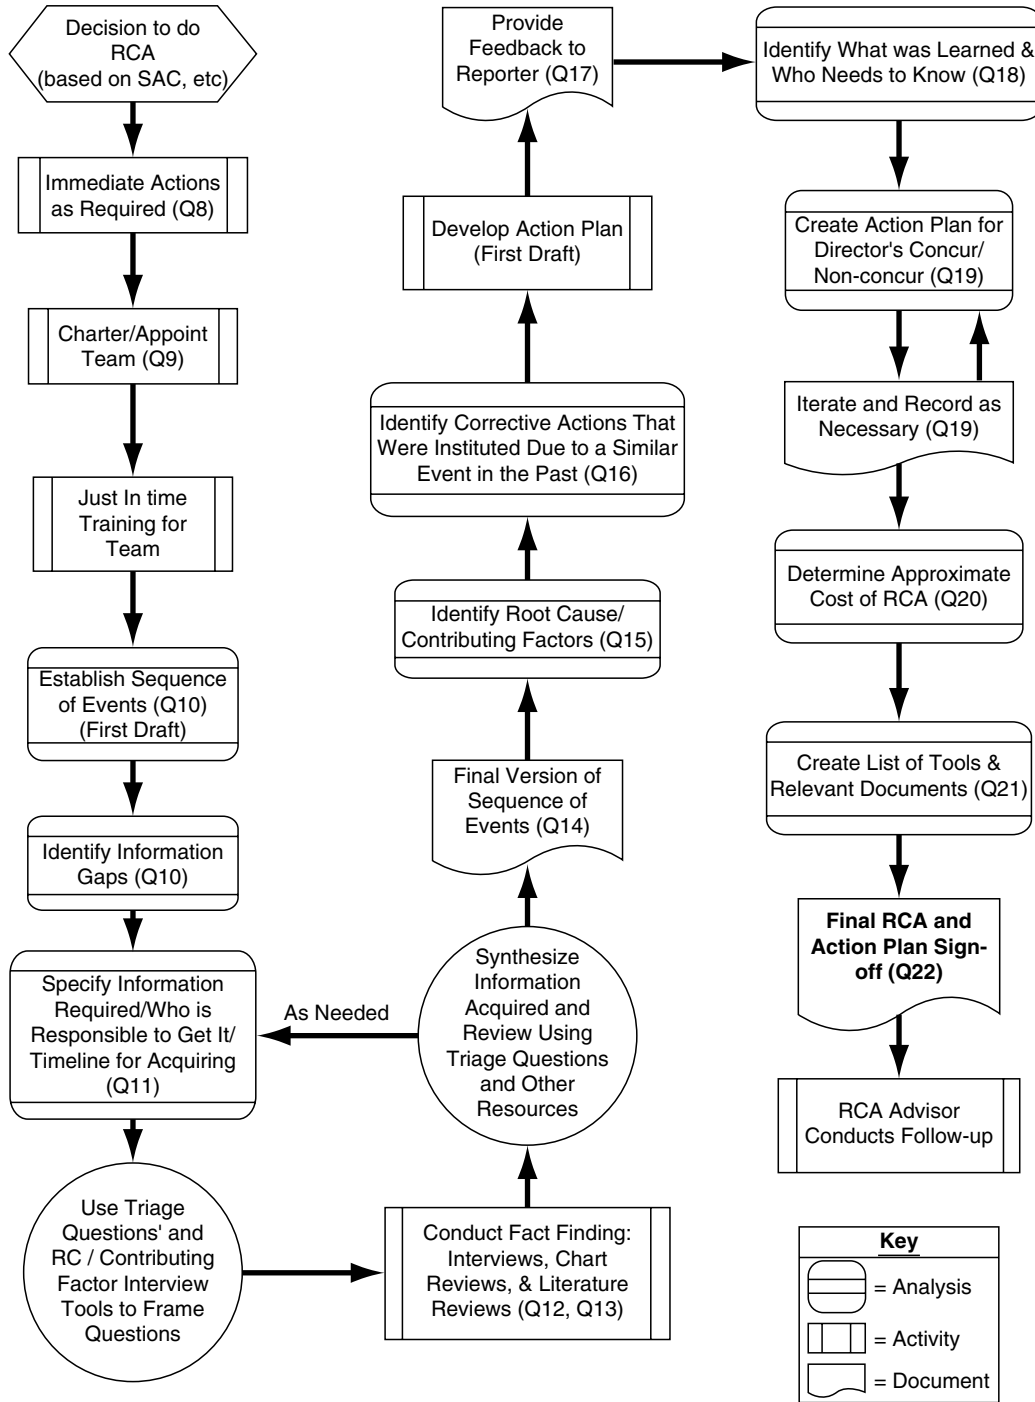

Figure 55-1 RCA team process.

- Determine the severity (Table 55-2) and probability (Table 55-3) of the potential failure mode and look up the hazard score on the Hazard Score Matrix™ (Table 55-1). Go to the HFMEA™ Decision tree (Figure 55-2). Use the decision tree to determine whether the failure mode warrants further action. Record the action to “proceed” or to “stop” on the HFMEA™ Worksheet (Figure 55-3).
- List all of the failure-mode causes for each failure mode where the decision is to “Proceed” and record them on the HFMEA™ Worksheet, Line 3. (Hint: Remember that failure-mode causes are the reasons why something could go wrong. Each failure mode may have multiple failure-mode causes. For example, possible failure-mode causes for not being able to log in and delayed login with a computer would include the computer not being available, no power, and no log-in ID for the operator.)

STEP 5 ACTIONS and OUTCOME MEASURES

- Identify a Description of Action for each failure mode that will be eliminated or controlled.
- (Hint: Place the control measure in the process at earliest feasible point. Multiple control measures can be placed in the process to control a single hazard. A control measure can be used more than once in the process. Solicit input from the process owners if they are not represented on the team. Try to simulate any recommended process change to test them before facility-wide implementation.)
- Identify outcome measures that will be used to analyze, and test the redesigned process.

Table 55-1 Hazard scoring matrix

Probability	Severity of effect			
	Catastrophic	Major	Moderate	Minor
Frequent	16	12	8	4
Occasional	12	9	6	3
Uncommon	8	6	4	2
Remote	4	3	2	1

To use this matrix: (1) Determine the severity and probability of the hazard based on the definitions included with this matrix. (NOTE: These definitions are the same as those used in the RCA safety assessment code.) (2) Look up the hazard score on the matrix.

- Identify a single, responsible individual by title to complete the recommended action.
- Indicate whether top management has concurred with the recommended action.
- Test to ensure that the system functions effectively and that new vulnerabilities have not been introduced elsewhere in the system.

How to Develop Reasonable and Concrete Failure Modes

There are several techniques besides brainstorming that should be used to develop reasonable and concrete failure modes once process diagrams are complete and the focus areas are chosen. Reviewing databases, such as the United States Food and Drug Administration (FDA) Manufacturer and User Device Experience (MAUDE), could provide malfunctions and user-interface design issues such as inadvertent shutdown of external pacemaker machines. Usability tests that are done by the HFMEA™ team or found in a literature search can be useful (Welch, 1998). Usability testing is a human-factors-engineering technique that can be done on devices, work areas, or larger processes (Gosbee et al., 2001).

Another technique is patient safety rounds. For example, upon sitting down with ICU nurses and residents, the CE may find that the nurses are worried about missing alarms several times a week because of distractions or noise levels and that they have nearly missed important alarms because of distraction or noise level. Another approach is to use the findings from routine safety-assessment tool “audits.” For example, the CE may find that many of the hospital’s compressed air wall outlets have green Christmas tree light adaptors attached; the VA’s approach to this issue has been to send out an alert that all facilities should switch to a clear adaptor. This thereby avoids the potentially hazard and vulnerability caused by matching the wrong color adaptor and thereby providing the wrong color cue.

In a complex and difficult HFMEA,™ video documentation can be done on high-hazard areas. The video analysis provides data on close calls or adverse events, and is one of the most concrete development tools to list failure modes. For example, the University of Maryland has used this for research into safety issues during respiratory arrest resuscitation (Xiao and Moss, 2001).

Those that have FMEA experience and skills may find themselves in demand to respond to the new JCAHO standards and need for proactive risk assessment within health care.

JCAHO Standards

The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) drives much of the activity within health care through its standards that must be met to gain accreditation. While voluntary, almost all hospitals choose to apply for JCAHO accredi-

Table 55-3 Probability rating

Frequent—Likely to occur immediately or within a short period (could happen several times in one year)
Occasional—Probably will occur (could happen several times in 1 to 2 years)
Uncommon—Possible to occur (could happen sometime in 2 to 5 years)
Remote—Unlikely to occur (could happen sometime in 5 to 30 years)

tation. The new LD 5.2 JCAHO patient safety standard reads as follows: “Leaders ensure that an ongoing, proactive program for identifying risks to patient safety and reducing medical/health care errors is defined and implemented.” The intent section clarifies that annually at least one high-risk process be examined. For this process it is required to identify failure modes, and for each failure mode identify the possible effects. For the most critical effects, conduct analysis of the systems issues that allow this to occur, and mitigate the serious issues.

Procurement Using Proactive Risk Assessment Model

CEs are called upon to fix, repair, maintain, and update equipment throughout the hospital and clinic environment. Skills gained in engineering schools and practical knowledge developed through work experience are applied in these traditional activities. However, CEs can broaden their impact by influencing procurement activities, thereby increasing the visibility of the CE department, improving the safety of the procurements, and improving the bottom line.

Engineers are taught to think in terms of systematic, logical, objective-based, well-supported conclusions. Consider researching the ways procurement decisions are reached and selling the capital acquisition committee on the added benefit of applying CE skills to the procurement process.

- Provide a proactive approach to procurement; think about what might go wrong with the different models under consideration and provide a modified failure mode effect analysis to compare different models
- Encourage end-user input into the procurement decision process
- Include consideration of past experience (good or bad) with the particular manufacturer
- Use existing data from databases of fellow CEs, ECRI, and MAUDE to support the safest purchase
- Develop explicit criteria to enhance an objective evaluation of the equipment

The CE department will be involved downstream in maintaining and fixing equipment brought into the facility. Why not become involved initially to make the most prudent purchase considering full life cycle costs, safety, and usability in your decision process?

Definitions

Effective Control Measure: A barrier that eliminates or substantially reduces the likelihood of a hazardous event occurring.

Health Care Failure Mode and Effect Analysis (HFMEA™): (1) A prospective assessment that identifies and improves steps in a process, thereby reasonably ensuring a safe and clinically desirable outcome; (2) a systematic approach to identify and prevent product and process problems before they occur.

Hazard Analysis: The process of collecting and evaluating information on hazards associated with the selected process. The purpose of the hazard analysis is to develop a list of hazards that are of such significance that they are reasonably likely to cause injury or illness if not effectively controlled.

Failure Mode: Different ways that a process or subprocess can fail to provide the anticipated result.

Probability: See the Probability Rating System (Table 55-3).

Severity: See the Severity Rating System (Table 55-2).

Table 55-2 Severity rating

<i>Catastrophic event (Traditional FMEA rating of 10-Failure could cause death or injury)</i>	<i>Major event (Traditional FMEA rating of 7-Failure causes a high degree of customer dissatisfaction.)</i>
<p>Patient outcome: Death or major permanent loss of function (sensory, motor, physiologic, or intellectual), suicide, rape, hemolytic transfusion reaction, surgery/procedure on the wrong patient or wrong body part, infant abduction, or infant discharge to the wrong family</p> <p>Visitor outcome: Death; or hospitalization of 3 or more.</p> <p>Staff outcome:* A death or hospitalization of 3 or more staff</p> <p>Equipment or facility: **Damage equal to or more than \$250,000</p> <p>Fire: Any fire that grows larger than an incipient</p>	<p>Patient outcome: Permanent lessening of bodily functioning (sensory, motor, physiologic, or intellectual), disfigurement, surgical intervention required, increased length of stay for 3 or more patients, increased level of care for 3 or more patients</p> <p>Visitor outcome: Hospitalization of 1 or 2 visitors</p> <p>Staff outcome: Hospitalization of 1 or 2 staff or 3 or more staff experiencing lost time or restricted duty injuries or illnesses</p> <p>Equipment or facility: **Damage equal to or more than \$100,000</p> <p>Fire: Not applicable – See Moderate and Catastrophic</p>
<i>Moderate event (Traditional FMEA rating of “4” – Failure can be overcome with modifications to the process or product, but there is minor performance loss.)</i>	<i>Minor event (Traditional FMEA rating of “1” – Failure would not be noticeable to the customer and would not affect delivery of the service or product.)</i>
<p>Patient outcome: Increased length of stay or increased level of care for 1 or 2 patients</p> <p>Visitor outcome: Evaluation and treatment for 1 or 2 visitors (less than hospitalization)</p> <p>Staff outcome: Medical expenses, lost time or restricted duty injuries or illness for 1 or 2 staff</p> <p>Equipment or facility: **Damage of more than \$10,000 but less than \$100,000</p> <p>Fire: Incipient stage‡ or smaller</p>	<p>Patient outcome: No injury, nor increased length of stay nor increased level of care</p> <p>Visitor outcome: Evaluated and no treatment required or refused treatment</p> <p>Staff outcome: First aid treatment only with no lost time, nor restricted duty injuries nor illnesses</p> <p>Equipment or facility: **Damage of less than \$10,000 or loss of any utility? without adverse patient outcome (e.g. power, natural gas, electricity, water, communications, transport, heat/air conditioning)</p> <p>Fire: Not applicable – See Moderate and Catastrophic</p>

Solutions

Staff vs. Line? Be neither. If one is serious about patient safety and is truly passionate about it, the ideal chain of command is an autonomous arm reporting directly to the board. The National Center for Patient Safety serves as a good model. The IOM report also recommends forming a National Center for private-sector hospitals using NCPS as a model. This will overcome two problems, delineated earlier in the document.

Conclusion

CEs are uniquely positioned to address patient safety issues. They have the proper education, the proper mindset, and solid experience, entrusted by the public and trusted by their peers. They are performing prospective and retrospective risk assessment on certain groups of medical devices. They need to expand their horizons and get involved with the multidisciplinary teams to conduct these risk assessment in all health care technologies and processes. Close to 90% of the hospitals in the United States are looking at the Practitioner Order Entry Systems (POE) and the Bar Code Medication Administration Systems (BCMA) to mitigate well-documented Adverse Drug Events (ADEs). These are truly complex, high-cost technologies with complicated process issues to which CEs should apply their expertise. CEs must play the role of Stewards to

Risk Management

Alice L. Epstein

CNA HealthPro
Durango, CO

Gary H. Harding

Greener Pastures, Inc.
Durango, CO

Risk management, the organized effort to identify, assess, and reduce physical and financial risk to patients, staff, and business, has deep roots both inside and outside of health care. Sweeping new initiatives by the United States and international regulatory agencies to inject risk management techniques into the development and use of medical devices have surfaced and are receiving increased attention. However, few new, innovative changes to the risk management process have occurred over the last 35 years, although some would argue otherwise (ASHRM, 1999). The authors concur with this statement on the basis of more than 20 years experience in health care risk management (Epstein and Harding, 2003). Surely, the names of processes, inventors, and regulations have changed with the introduction and remodeling of old concepts into newly titled ones, but the actual need to identify, assess, and manage risk overshadows the sparkle of the new name one applies to the process or the honor bestowed upon its inventor.

The following applications each include aspects of risk management:

- Enterprise risk
- Total quality management (TQM)
- Performance improvement (PI)
- Quality inspection system technique (QIST)
- Failure mode and effect analysis (FMEA)
- Corrective and preventive action (CAPA)
- Risk analysis—ISO/IEC 14971 Clause 7
- Root cause analysis (RCA)
- Six Sigma
- Title 21, Chapter 1, Part 820 (Quality System Regulation)

Risk management is not about complying with the latest concept or approach, i.e., complying precisely with the letter of the risk management technique in vogue. Rather, it is about taking the steps necessary to effectively identify, assess, and address risk.

Risk management is not about placing blame. Multiple studies have found that accidents and incidents do not decrease in an environment of blame. Rather, accidents and incidents most often occur because of system failure. The adverse occurrence is rarely caused by the actions of one individual. Usually there is a series of actions and resultant interactions that allow the event to occur. Most failures have resulted from the lack of attention to one or more aspects of the basic risk management techniques that have been available for over 35 years. Blind adherence to a process in vogue may be the greatest impediment to successful risk management. A process may be accepted by one group, but it may conflict with the processes and viewpoints of another group and stifle communication.

Risk management is all about communication—communication of information among health care professionals and sometimes with others, for example, the patient, the alternate caregiver, and the insurer. It is all about ensuring that the proper risk management techniques are in place and that they are in use consistently. While there are differences in actual operational application of risk management techniques, the basic tenets of risk management are the same for health care clinical processes, health care, clinical engineering device management, and medical device manufacturers. This chapter discusses risk-management basics, pertinent regulatory authorities, and specific risk management issues from the perspective of the hospital clinical engineer. Resources are provided not only to address specific clinical engineering issues but also to provide the experiences of industries that have successfully applied the basic tenets of risk management from which others can and should learn.

Definitions of Risk Management

Kavaler and Spiegel define risk management as “...an organized effort to identify, assess, and reduce where appropriate, risks to patients, visitors, staff, and organizational assets” (Kavaler

and Spiegel, 2003). The American Society of Health care Risk Management (ASHRM) defines risk management as “The process of making and carrying out decisions that will assist in prevention of adverse consequences and minimize the adverse effects of accidental losses upon an organization. Making these decisions requires the five steps in the decision process A systematic and scientific approach in the empirical order to identify, evaluate, reduce, or eliminate the possibility of an unfavorable deviation from expectation and, thus, to prevent the loss of financial assets resulting from injury to patients, visitors, employees, independent medical staff, or from damage, theft, or loss of property belonging to the health care entity or persons mentioned. The definition includes transfer of liability and insurance financing relative to the inability to reduce or eliminate intolerable deviations.” (ASHRM, 2003), in a contract for the Canadian government, defined risk as follows, “For the most part, risks are perceived as any thing or event that could stand in the way of the organization achieving its objectives” (Treasury Board of Canada Secretariat, 1999).

Hence, for these organizations, risk management is not about being “risk averse.” Risk management is not aimed at avoiding risks. It has as its focus the identification, evaluation, control, and mastering of risks. Risk management includes taking advantage of opportunities and taking risks based on an informed decision and analysis of the possible outcomes. Snow related that risk management in medical device design and production is composed of five core activities – planning, risk analysis, risk evaluation, risk control, and postproduction control (Snow, 2001).

History of Risk Management in Health Care and Related Industries

The concept of risk management developed from within the insurance industry. Primarily related to the theories of legal liability (e.g., malpractice, product liability, errors and omissions, and completed operations); the insurance industry had and still maintains a direct interest in reducing the occurrence and impact of adverse events. Simply put, if the insurer received a premium to provide insurance for accidental loss, and actual losses were below the value of the premium attained, a profit might be made by the insurance provider. If a situation developed wherein the losses due to adverse events (e.g., an insured ship sank) exceeded premium attained, not only was the insured in danger of going out of business, but so was the insurer. For self-preservation, insurers developed and applied the concept of risk management many years ago.

While Kavaler points out that the principles of risk management in medicine date back to the Code of Hammurabi, under which a surgeon might be bound to lose a hand if a patient lost an eye as a result of medical treatment, the emphasis in this review is more recent. With respect to the practice of medicine, the introduction and application of risk management in health care was designed as a response to a medical malpractice crisis in the 1970s, due in large part to significant jury awards and a decrease in investment returns for large insurance carriers. Decreased investment returns led to increased medical malpractice insurance premiums, and caused some malpractice insurance carriers to cease selling insurance policies to physicians and health care organizations.

For many years, the practices related to risk management for medical device manufacturing developed along with other manufacturing sectors, for example, heavy equipment and automotive, without special emphasis on health care. In the past few decades (late 1990s and 2000s), a heightened recognition of and emphasis on the application of risk management to medical devices outside of the insurance industry has occurred with the introduction of the United States Medical Device Amendments of 1976 and the continuing development of the Food and Drug Administration Center for Devices and Radiological Health (formerly known as the Bureau of Medical Devices and the Bureau of Radiological Health). One driving force was the Institute of Medicine (IOM) report on medical errors, with an emphasis on taking the steps necessary to reduce the occurrence

of these errors (Kohn et al, 2000). Another driving force could be the implementation of caps, that is, limits of liability, by state governments for hospitals and health care providers, which limit their financial exposure to, for example, \$250,000. Such caps make any other party to a lawsuit, e.g., surgeons and medical device manufacturers, the only remaining “deep pockets,” i.e., those parties with substantial financial resources, from which the injured party can extract the potential multimillion dollar awards for costs of medical care, pain and suffering, and the loss of consortium.

Health Care Operational Risk Management Overview

Health care risk managers have various training and backgrounds, including health care administration, nursing, insurance, risk management, law, quality improvement, medical records, facilities management, and even (although a rare occurrence) clinical engineering. While there are universities and colleges offering bachelor's and master's degrees in risk management, none specialize in health care risk management at present. The majority of risk managers in the health care field have been trained in a discipline within health care, either clinical or administrative, from which they grew into the roles of risk managers. Certification in health care risk management through testing and experience is available from ASHRM, an individual membership group of the American Hospital Association. A broader, insurance-industry certification is available from the Insurance Institute of America, which offers the designation of Associate in Risk Management (ARM) after successfully completing three courses and accompanying examinations.

Risk Management Process

To apply risk management to the department of clinical engineering, one must understand the basic components of the risk management process. The process consists of five steps:

1. Identify and analyze exposures.
2. Consider alternative risk treatments techniques.
3. Select the best technique to manage and treat the risk.
4. Implement the selected technique.
5. Monitor and improve the risk management program risk management program.

Risk Management Program Structure

Risk management structures and operations may differ from health care organization to organization, even within the same community, city, state or region. While there are certain elements common to most risk management programs, specific functions vary according to the complexity of the organizations and interests of the governing body and chief administrative officer. As the responsibilities defined under various risk management program risk management programs differ, so will the role of the clinical engineer in risk management. All risk management programs are based on patient safety and the preservation of assets, and have risk identification and loss prevention as their fundamental components. ASHRM has suggested that there are six functional areas within a comprehensive risk management program:

- Risk identification and risk treatment through loss prevention and reduction
- Claims management
- Risk financing
- Regulatory and accreditation compliance
- Risk management departmental operations
- Bioethics

Risk Identification

Risk identification is the process through which the engineer becomes aware of the potential for a loss exposure. An exposure can include patient injury, loss of an asset, plaintiff verdicts and malpractice payments, loss of reputation, or governmental fines. Methods often implemented to identify potential and actual risk include incident reporting, generic occurrence screening, patient complaints, patient satisfaction surveys, accreditation survey reports, insurance carrier risk assessment reports, and state licensure surveys. Clinical engineering problem reports, unexpected or unacceptable equipment downtime, and MDR reports could also be used to identify potential or actual adverse events. All too often, risk managers are unaware of these engineering databases and do not integrate them into an organization's loss prevention reports.

Risk Treatment

Risk treatment refers to the options and choices available to handle a specific risk. Risk can be controlled internally through risk avoidance/prevention or risk reduction/minimization. Risk can be controlled financially through risk acceptance/retention or risk transfer. Risk avoidance is used when the risk is considered significant enough to avoid the risk by avoiding the action that would create exposure to it. For example, an organization in a rural setting may not be able to hire adequate staff for a neonatal intensive care unit. Therefore, the organization would only perform well-baby deliveries and transfer all high-risk deliveries.

Risk reduction is the most common risk management treatment. For example, an organization without a neonatal intensive care unit may have emergency equipment such as a radiant warmer, an on-call system for staff with basic neonatal resuscitation training, and a transfer agreement with a NICU in case of high-risk deliveries that an organization can not foresee or avoid.

Risk acceptance involves assuming the potential losses associated with a given risk, such as precipitous high-risk deliveries, and making plans to cover the potential financial costs of the risk. In order to cover the cost of a high-risk delivery with complications, an organization may decide to pay for insurance with low deductibles (typically a high-cost option as the insurance company essentially pays almost the first dollar on every loss) or assume high deductibles within the insurance program and pay for many of them out-of-pocket.

Risk transfer means recognizing that medical care can not be provided without assuming some risk. Therefore, an organization may insure for possible misadventures, which transfers the risk to the insurer, or assign responsibility to another service provider (e.g., independent clinic or surgicenter), which transfers the risk to the service provider or its insurer.

Evaluation and monitoring of the implemented risk-treatment technique selected is essential to determine the effectiveness of the choice. Evaluation of the treatment should be multidisciplinary whenever possible, as other disciplines bring varying insights into the success or failure associated with the chosen techniques. Benchmarks or thresholds should be established prior to the implementation of a technique so that measurement can be made against defined parameters.

Claims Management

Apart from the actual physical injury that an adverse event can cause to patients or staff, the risk to the organization may be a lawsuit. Claims management includes activities associated with managing potential and actual claims or lawsuits. Serious adverse events are often treated as potential litigation, and as such, information must be gathered and protected. Sometimes the protection of information may seem contrary to the clinical engineer's professional tendency to share information in order to optimize an investigation and minimize the likelihood of another similar injury. There is a balance that must be struck. Appropriate professionals both inside and outside the organization should discuss the issue of protection of information versus the common good. Protection may include sequestering medical devices thought to be involved in a serious incident, deciding whether a third-party independent investigation is necessary, interviewing involved staff members, and locating user manuals, policies, and procedures.

Risk Financing

Risk financing consists of activities to finance losses. This strategy includes maintaining and coordinating exposure data and values, for example, capital inventory, disposable values, replacement costs, and utility interruption costs. The most common method of financing the cost of risk is through the purchase of insurance. Organizations must make decisions regarding what to insure, the justification for the insurance, coverage limits, deductibles, and attachment points to ensure that all exposures are adequately covered. The legal liability of clinical engineers has been discussed in the chapter by Richards and Walter. Although insurance does not protect an engineer from being found guilty of faulty practice or negligence, it can provide financial assistance in the form of defense costs and payment of jury awards if the engineer is found guilty. The insurance company can eliminate the tribulations associated with a court case if the decision is made to settle a case with payment to the injured party before the case goes to court. Insurance policies rarely, if ever, will cover the cost of fines imposed by the court. The health care organization can purchase insurance for the professional actions of the engineer, product liability exposures, completed operations, errors, and omissions, and employee on-the-job injuries.

Contract Review

Contract review is integral in evaluating the adequacy of insurance, since contracts can contain both harmless and indemnifying language. In addition, an organization must ensure that outside contractors, such as installers, are adequately insured for work-related injuries and the liability of their errors and omissions. While the risk manager may be aware of the need to finance these risks, the clinical engineer can participate in the technical oversight in order to be sure that outside contractors actually perform up to the expected standards.

Data Collection, Analysis, and Reporting

Risk managers must develop reports to demonstrate trends and indicators for the governing body and administration relative to adverse event reporting, loss prevention activities, and investigations. The risk management department may be responsible for developing policies and procedures related to patient safety activities such as informed consent, adverse event reporting and disclosure, product recall, and confidentiality. The department may develop and provide educational programs for these topics. In some hospitals, risk managers find themselves responsible for developing a program for management of adverse event exposures resulting from contracts, affiliation agreements, leases, purchase agreements, and warranties.

Governmental and Professional Organizations' Contributions to the Importance of Health Care Risk Management

The American College of Surgeons (ACS) was one of the first medical professional organizations to recognize the importance of a systematic approach for improving patient safety. In 1979, the ACS published the first edition of the patient safety manual as a response to the malpractice insurance crisis of the mid-1970s. The ACS created the patient safety system as a program that coordinated related functions of quality assurance, risk management, medical staff credentialing, and peer review. The goals of the patient safety system were to improve the quality of patient care, reduce preventable patient risks, and manage losses due to professional liability. The system's creators envisioned collaboration between hospital governance, management, and the medical staff. Using quality of care as a guiding ethic, they found four common interests involving patient safety (American College of Surgeons, 1985).

1. Minimize risks of patient injury.
2. Minimize financial losses due to malpractice awards and settlements.
3. Use hospital resources appropriately and cost-effectively.

4. Meet JCAH/JCAHO requirements. In 1985, what is now known as the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) was the Joint Commission on the Accreditation of Hospitals (JCAH). See Chapter 121 for a description of the JCAHO.

Safety engineering was considered an important element in the risk management function of the patient safety system. The ACS believed there should be an organized safety engineering or clinical engineering program and a systems approach to the safe use of medical equipment that included the development of a relationship with quality assurance and risk management professionals.

The ACS recognized that although hospitals rely heavily on modern medical technology, the human factor was the key to patient safety. "The patient's safety depended not on a piece of equipment, but rather, on the health professional responsible for purchasing equipment, checking it prior to use, operating it properly, assuring correct settings, reporting problems to the engineer, and documenting preventive maintenance" (American College of Surgeons, 1985). The risk management aspects of a safety engineering department included incident reporting and follow-up for equipment-related occurrences, pre-purchase review, preoperation testing, staff training, preventive maintenance, and documentation. In addition, the ACS recognized the need for an in-house medical device recall system to ensure that staff members were aware of confirmed equipment hazards related to equipment in use or considered for purchase. The system required monitoring of product recalls and service notices from manufacturers, government agencies, and independent reviewers, as well as reporting hazardous equipment to the Food and Drug Administration (FDA) and manufacturers. See Chapter 126 for more information on this subject. The inclusion of these elements brought clinical engineering into the mainstream of risk management. Was the ACS's concern that a malfunctioning device could jeopardize the safety of future patients was a driving force for including product information in risk management plans.

Integral risk management elements of the clinical engineering program included the procedures for investigation following an equipment-related incident, the need for formal preventive maintenance procedures, and clinical staff training in the safe and effective use of medically-related equipment. The ACS recommended that the program elements be audited every 3-5 years to identify the strengths and weaknesses of the existing programs and to target priority areas needing improvement.

Another aspect of the patient safety system was the development of a response plan for equipment-related incidents. The ACS stated that equipment involved in an adverse event should not be returned to service without careful inspection and repair if warranted. They noted that the reason for the device failure may be an important defense in a malpractice claim, especially if the hospital seeks to transfer some or all of the liability to the equipment manufacturer or service vendor. The response to the incident required completion of the incident report form and prompt submission to the risk manager, tagging of the suspect device, and removal of the device from service. In coordination with the risk manager, the device should be tested by the hospital's engineering department or a qualified outside party. The ACS emphasized that the device should not be tested by the manufacturer. Only after testing should the hospital decide whether the device should be repaired and returned to service, held for evidentiary purposes, or returned to the manufacturer. The defect found in the device should be documented and any similar devices in the facility should be examined. Hospitals should report any incidents to the FDA national Problem Reporting Program (termed the PRP and one predecessor to today's MedWatch program). Only then should the manufacturer be notified that the device was potentially involved in a patient injury and that the injury may result in a claim.

The National Patient Safety Foundation (NPSF), was founded in 1996 by the American Medical Association (AMA) as a collaborative initiative involving all members of the health care community. It was developed to stimulate leadership, foster awareness, and enhance the knowledge, dissemination, and implementation of patient safety protocols. The NPSF attracted attention in 1999 when the November release of the patient safety report by the Institute of Medicine (IOM) of the National Academy of Sciences put patient safety in the national spotlight. The IOM report defines safety as freedom from accidental injury. Distinguishing between medical accidents and errors was a significant step in framing accident investigations. The word *error* has a judgmental quality, while *accident* recognizes the complexity of the event. The study reported that preventable adverse events are a leading cause of death in the United States. The results of two studies imply that at least 44,000 and perhaps as many as 98,000 Americans die in hospitals each year as a result of medical errors when extrapolated to the approximately 33.6 million admissions to U.S. hospitals in 1997. Although the majority of these accidents are related to medication errors, one study cited in the IOM report found that 44% of preventable adverse events have been attributed to technical errors, which include equipment and systems failures (Kohn et al, 2000). The CDHR estimates that approximately one-third of the 80,000 device reports they receive each year may involve medical equipment "use error" (Campbell, 2001).

Following the dissemination of these reports, several agencies began studying the best methods to improve patient safety. In 2001, the Agency for Healthcare Research and Quality (AHRQ) released an Evidence Report/Technology Assessment, entitled *Making Health Care Safer: A Critical Analysis of Patient Safety Practices*, which reviewed evidence from 79 patient safety practices (AHRQ, 2001). The report listed 73 practices that could improve patient safety and described 11 practices that the researchers considered workable but are not performed routinely in the nation's hospitals and nursing homes. The following patient safety practices are relevant to clinical engineers:

- Preanesthesia checklists to improve patient safety
- Recognizing the impact of intraoperative monitoring on patient safety
- Using human factors to reducing device-related medical errors
- Refining the performance of medical device alarms (e.g., balancing sensitivity and specificity of alarms and ergonomic design)

In 2003, the National Quality Forum (NQF) released a consensus report entitled *Safe Practices for Better Health Care* (NQF, 2003). The report details 30 health care practices that the NQF considers appropriate in applicable clinical care settings to reduce

the risk of harm to patients. The report focuses on practices that meet the following criteria:

- They have strong evidence that they are effective in reducing the likelihood of harming a patient.
- They are generalizable (i.e., they may be applied in multiple clinical care settings and/or multiple types of patients).
- They are likely to have a significant benefit to patient safety if fully implemented.
- They are useful for consumers, purchasers, health care providers, and researchers.

Practices that may be of importance to clinical engineers who work with electronic data and information management include:

1. Creating a health care culture of safety.
2. Preparing patient care summaries or other similar records from documented information, not from memory.
3. Ensuring that health care information, especially changes in orders and new diagnostic information, is transmitted in a timely and clearly understandable form to all of the patient's current health care providers.
4. Implementing a computerized prescriber order entry system.
5. Implementing a standardized protocol to prevent the mislabeling of radiographs.

The American College of Clinical Engineering (ACCE) emphasized the role of the clinical engineer in patient safety in its White Paper, *Enhancing Patient Safety: The Role of Clinical Engineering* (ACCE, 2001).

Regulatory and Accreditation Compliance as Risk Management Tools

Risk managers are often tasked with overseeing regulatory and accreditation compliance, since compliance is a fundamental risk management tool. If the organization meets regulations and standards, they are better able to control risk and demonstrate to a jury that they have met the standard of care. Clinical engineers may be responsible for compliance with the following:

- State and federally required reporting of certain types of adverse events and incidents
- Life Safety Codes
- Occupational Safety and Health Administration Act
- Needlestick Safety Prevention Act
- Patient Self-determination Act
- Safe Medical Devices Act
- Health Care Quality Improvement Act
- Emergency Medical Treatment and Active Labor Act
- Health Insurance Portability and Accountability Act

The Clinical Engineer's Role in Risk Management

Risk management is an art, not a science. While there have been attempts to measure risk and the effectiveness of risk treatments, such measurements are based on experiences, not hard and fast scientific equations. Management of equipment-related patient injury risk is a combination of equipment assessment, appropriate training, proper clinical technique, preventive maintenance, and failure analysis (Maley and Epstein, 1993). The selection of the safest equipment may be ineffective in controlling risk if preventive maintenance, software upgrades, and overhaul requirements do not take place. "Gradual deterioration without maintenance may bring the safety level below an acceptable level of manageable risk" (Gullikson, 2000). A number of clinical engineers (Gullikson, 2000; Ridgway, 2001; Dolan, 1999) have attempted to address proactive risk management through the identification of preventive maintenance risk factors as occurrences, such as the return of equipment for service within nine days. However, there is no consensus or hard, well-supported data upon which to assess and accept such factors. While some engineers may identify failure to pass a preventive maintenance procedure as an occurrence, there is no well-supported information to indicate that such a device is any greater risk to patients than a device that passed the preventive maintenance procedure. The use of algorithms to identify critical devices or risk factors for medical devices that constitute actual risk of injury may be the clinical engineering profession's best attempt to proactively address risk, but clinical engineers should recognize the limitations of the practice and not rely solely on such algorithms.

Clinical engineers can contribute to the risk management function, both within their respective departments and in the larger scope of facility-wide risk management. The primary methods all hospitals use to facilitate risk identification are incident (also known as adverse event) reporting, medical record review, and patient complaints. It is easy to visualize the role clinical engineering should play in the reporting and investigation of adverse events, since patient equipment is in use at the time of most adverse events.

Risk managers are often responsible for developing and maintaining collaborative relationships with other hospital departments related to the identification and treatment of risk. If the risk manager is unaware of the capabilities of the clinical engineering department with respect to problem identification and investigation (a limitation all too common in the authors' experience), the risk manager may not involve the clinical engineer in the process until he or she understands how a device can play a role in an adverse event. For example, a device may seem to operate properly in performance testing after an adverse event, but radiofrequency interference may have caused erratic operation of the device in the actual environment of use.

Other chapters in this handbook emphasize the importance of clinical engineering in the acquisition of new technologies (See Chapters 30-34). Due diligence, as a risk-management

tool, should be completed for all new acquisitions of facilities and equipment. Many health care organizations are merging or purchasing complete facilities or existing services. Preacquisition risk analysis can help administrators make a more educated decision on whether or not to proceed with the acquisition. Such analysis can also help administrators determine terms that should be included to control risks and steps that may need to be taken after the acquisition to address risks. An interdisciplinary team including the clinical engineer can review the clinical, facility, and equipment issues on a preacquisition basis to offer information on ways to control risk that may contribute to a better acquisition opportunity from a financially or other perspective.

Proper risk management dictates basic requirements for all hospital departments. Policy and procedure manuals must reflect the actual operations of the department. Whether the policy and procedure manual is borrowed from another facility, purchased from a commercial vendor, or provided by the manufacturer in-house professionals must review the information to ensure that each policy or procedure accurately reflects the functions performed and is appropriate for the department and the facility. For example, does the document represent the standard of care as practiced at the facility? Can the staff meet the requirements of the policy or procedure?

Each policy should be identified with a policy number and the date of inception. As policies and procedures are removed from service or revised, a copy of the retired policy should be archived for a minimum of seven years. Each policy and procedure manual should be reviewed at least biannually and as needed. Policies and procedures can be updated and revised at any time. However, as old policies and procedures are retired or new policies and procedures are introduced, all manuals should be updated, and all affected staff should be apprised of the change. If there is a policy that affects more than one department, e.g., nursery equipment preventive maintenance schedules, all related departments should incorporate and understand the identical policy.

Although seemingly obvious, all policies and procedures should reflect the name of the health care organization using the document. If borrowed documents are used, the name of the originating facility should be removed. Obtain permission in writing from the originating facility to utilize a policy within another organization. If there are blank spaces included in a commercial policy or procedure, the blanks should be completed with the information required.

Policies and procedures should reflect the national state of practice. If there is an injury and a related policy and procedure does not reflect the current accepted standard of practice, a jury would be hard-pressed to understand why the health care organization could not or would not meet that standard.

User manuals should be present at the location in which equipment is used and clinical staff should be made aware of the availability and location of the manuals. The manuals should not be locked away for safekeeping.

Risk management dictates that staff be adequately trained in their job functions and understand their individual contributions to risk management and patient safety. In-service education, continuing education, and manufacturers training should be well-documented. Documentation should include names of attendees, course content, program sponsor, evidence of attendance, and date of attendance.

Medical device training is important for clinicians as well as for the clinical engineer. Clinicians' user errors and improper use of medical devices have been linked to multiple patient injuries. The FDA MedWatch and Manufacturer and User Device Experience (MAUDE) data indicate that user error and improper use are the two most often-cited reasons for patient injury. Since most of the entries in the FDA MedWatch and MAUDE are manufacturer-generated, it is not surprising if their reports may appear to shift responsibility and risk to the clinician and health care organization. It is important to note that plaintiff's legal counsel may use these reports to assert responsibility by the clinician and health care organization. Therefore, clinicians must have adequate training specific to the medical devices being used. Clinical competency checks are imperative, especially for high-tech equipment or where experience shows a need for special training. Refresher and remedial clinical training may be indicated.

Clinical engineers should be aware that manufacturers of medical devices are under increasing regulatory pressure to measure and address risk associated with their devices. While a discussion of medical device manufacturer risk management is beyond the scope of this chapter, clinical engineers should know that information about the risk character of a medical device may be available from the FDA or the manufacturer. Alerting the risk manager to the potential availability of such information may assist the risk manager in properly transferring risk and loss to a medical device manufacturer when appropriate.

Clinical engineers must be cognizant at all times of the potential discoverability of information by litigants and others. Routine documentation, memoranda, laboratory test notebooks, and investigation data may all be discoverable by litigation opponents. It is important to learn appropriate methods of writing and maintaining documents. While document control is not intended to alter the truth, it is intended, to the extent possible, to document only factual information and minimize unnecessary conjecture or opinion.

Statutory Risk Management Requirements

The Emergency Medical Treatment and Active Labor Act (42 USC 1395dd; 42 CFR 489, et al.) requires that anyone who presents at a hospital for what he or she believes is an emergency condition is entitled to a screening assessment and any needed stabilizing treatment. For the clinical engineer, this indicates the need to ensure that the equipment necessary to stabilize patients in an emergency is readily and always available and operational.

The Patient Self Determination Act of 1990 (42 USC 1395cc) requires that health care organizations inform patients about their rights regarding decisions about the course of their treatment, even if they are incapable of expressing those decisions at a later date. For the clinical engineer, this infers that inpatient health care organizations must be capable of preserving, terminating or removing artificial life support. Ventilators, feeding pumps, and other life-support equipment must be available and in working condition.

The Safe Medical Device Act of 1990 (21 USC 360; 21 CFR 803) requires that the FDA gather and health care organizations report information regarding the safety of medical devices. See Chapter 126. Sometimes, the clinical engineer is the primary operational department, reporting directly to the FDA. However, the risk management department may assume this role. Regardless of the reporting department, the information and responsibilities must be shared between the clinical engineer and the risk manager.

The Mammography Quality Standards Act of 1992 (42 USC 263; 21 CFR parts 16, 900, 1308, 1312, 42 CFR part 498) requires annual facility compliance inspections by an FDA-approved accrediting body, adherence to specified equipment testing and maintenance protocols, and implementation of quality control programs.

The Protection of Human Subjects Act (45 CFR part 46, 21 CFR parts 50, 56, 312, 812) addresses issues related to clinical trials of drugs and devices. Clinical engineers may become involved in the approval and clinical trial process any time a clinical trial of a device is being considered at the healthcare facility (See Chapter 87). Participation on the Institutional Review Board (IRB) on an ad hoc basis is recommended whenever a device is involved.

The Needlestick Safety Prevention Act (P.L. 106-4) requires that safety devices be used whenever possible. Clinical staff may resist changing their practices, even though the new device or technique is safer and does not affect clinical efficacy. Clinical engineers can identify clinicians in other facilities who are successfully implementing safety products and ensure that device trials are properly structured to examine clinical utility and safety without bias. See Chapter 61.

OSHA has many provisions that affect clinical engineering:

- Control of exposure energy to hazardous energy standard, commonly referred to as the Lockout/Tagout Standard, applies to any situation in which an unexpected energization of equipment or the release of stored energy could occur and injure an employee. The standard requires that equipment be locked out, i.e., rendered unusable unless a lock is removed during repair work. If a piece of equipment cannot be locked out, it must be tagged to warn other employees not to turn it on. OSHA requires a detailed educational program and plan to comply with this regulation.
- Regulation of mercury exposure may involve clinical engineers in evaluating the effectiveness of mercury-free devices such as sphygmomanometers, thermometers, and gauges.
- Regulation of exposure to methyl methacrylate, used in orthopedic surgery, should involve clinical engineers in the selection and maintenance of mixing hoods and laser exhaust and smoke evacuator systems (See Chapter 108).
- Additional chemicals with exposures governed by OSHA include acetone, alcohol, benzene, toluene, and xylene.
- OSHA also governs exposure to airborne contaminants and tuberculosis. Clinical engineers may be involved in the design of special rooms and the selection of respiratory-protection equipment (See Chapter 114).
- OSHA does not directly regulate exposure to antineoplastic and chemotherapy drugs; however, it issued guidelines on these subjects in its technical manual in 1995. If these drugs require reconstitution before use, they should be mixed in a Class II Biological Safety Cabinet, preferably one that is vented to the outside of the building. HEPA filtration cabinets also may be used, but they are less efficient.
- Although OSHA does not regulate exposure to laser and electrocautery plumes, these plumes have been shown to carry intact, viral DNA, bacteria, chemical vapors and gases, mutagenic materials, carcinogens, cyanides, formaldehyde, and smoke particles (West, 2001).

Accreditation as a Risk Management Technique

Clinical engineers are usually familiar with the accreditation requirements that are specific to their department; they should also be familiar with organization-wide standards that may affect their operations. For example, JCAHO utility-management requirements may not be the responsibility of clinical engineers, yet the requirements may affect proper operation of equipment.

The JCAHO has included patient safety and clinical engineering-related standards since its first published standards in 1953. Acute care hospitals are not the only organizations accredited by the JCAHO. Accreditation is also available through the JCAHO for the following enterprises:

- Psychiatric, children's, critical access, and rehabilitation hospitals
- Home care organizations, including those that provide home infusion and durable medical equipment services
- Nursing homes and other long term care facilities
- Behavioral health care organizations
- Ambulatory care providers, outpatient surgery facilities, rehabilitation centers, infusion centers, group practices as well as office-based surgery
- Clinical laboratories, including blood-transfusion and donor centers.

The JCAHO is supported by the American Hospital Association, American Medical Association, American College of Physicians, American Society of Internal Medicine, American College of Surgeons, and American Dental Association. Nurses have an at-large representative.

The JCAHO has integrated patient safety and elements of risk management into its performance improvement standards. The 2004 JCAHO risk management-related standards include the requirement for health care organizations to manage safety by identifying risks, and planning and implementing processes to minimize the likelihood of those risks causing incidents. The standards further require that the organization conduct proactive risk assessments that evaluate the potential adverse effects of equipment on the safety and health of patients. In addition, organizations must define and implement an ongoing, proactive program for identifying and reducing unanticipated adverse events and safety

risks to patients. The commission believes that “such initiatives have the obvious advantage of preventing adverse events rather than simply reacting when they occur. This approach also avoids the barriers to understanding created by hindsight bias and the fear of disclosure, embarrassment, blame, and punishment that can happen after an event.”

The performance improvement process is composed of the following activities:

- Collection of data to monitor performance
- Systematic aggregation and analysis of data, with analysis of undesirable patterns or trends in performance
- Implementation of processes for identifying and managing sentinel events
- Use of information from data analysis to make changes that improve performance and patient safety and reduce the risk of sentinel events

Organizational performance improvement requirements for the collection of patient safety data include gathering staff perceptions of risks to patients and suggestions for improving patient safety, as well as staff willingness to report unanticipated adverse events.

JCAHO outlines the following proactive performance improvement activities to reduce risks to patients:

1. Select a high-risk process (i.e., a process that if not planned and/or implemented correctly, has a significant potential for impacting the safety of the patient, to be analyzed).
2. Describe the chosen process (e.g., through the use of a flowchart).
3. Identify the ways in which the process could break down (i.e., the failure modes or fail to perform its desired function).
4. Identify the possible effects that a breakdown or failure of the process could have on patients and their potential severity.
5. Prioritize the potential process breakdowns or failures.
6. Determine why the prioritized breakdowns or failures could occur, this may include performing a hypothetical root cause analysis.
7. Redesign a risky process and/or underlying systems to minimize the risk patients.
8. Test and implement the redesigned process.
9. Monitor the effectiveness of the redesigned process (JCAHO, 2004).

The 2004 risk management standards also include the requirements that all equipment is maintained appropriately and that the organization ensures responses to product safety recalls. The two standards written specifically for the clinical engineering department are short, concise, and to the point: “The organization manages medical equipment risks,” and “Medical equipment is maintained, tested, and inspected” (JCAHO, 2004). There are, however, many requirements to meet these two standards.

Management of equipment risks requires the following:

1. Development of a written management plan describing the processes to manage the effective, safe, and reliable operation of medical equipment.
2. Identification and implementation of a process(es) for selecting and acquiring medical equipment.
3. Establishment and use of risk criteria for identifying, evaluating, and creating an inventory of equipment for inclusion in the medical management plan before the equipment is used. Criteria to address include equipment function (diagnosis, care, treatment, and monitoring), physical risks associated with use, and equipment incident history.
4. Identification of appropriate strategies to achieve effective, safe, and reliable operation for all equipment on the inventory.
5. Defined intervals for inspecting, testing, and maintaining appropriate equipment on the inventory (i.e., those medical devices on the inventory benefiting from scheduled activities to minimize the clinical and physical risks) that are based upon criteria such as manufacturers’ recommendations, risk levels, and current organizational experience.
6. Identification and implementation of processes for monitoring and acting on equipment hazard notices and recalls.
7. Identification and implementation of processes for monitoring and reporting incidents in which a medical device is suspected in or contributed to the death, serious injury, or serious illness of any individual, as required by the Safe Medical Devices Act of 1990.
8. Identification and implementation of processes for emergency procedures that address:
 - (a) What to do in the event of equipment disruption or failure
 - (b) When and how to perform emergency clinical interventions when medical equipment fails
 - (c) Availability of backup equipment
 - (d) How to obtain repair services

Maintenance, testing, and inspection of medical equipment requires documentation of the following:

1. Current, accurate, and separate inventory of all equipment identified in the medical equipment management plan, regardless of ownership.
2. Performance and safety testing of all equipment identified in the medical management program before initial use.
3. Maintenance of equipment used for life support that is consistent with maintenance strategies to minimize clinical and physical risks identified in the equipment management plan.
4. Maintenance of non-life-support equipment on the inventory that is consistent with maintenance strategies to minimize clinical and physical risks identified in the equipment management plan.
5. Performance testing of all sterilizers used.
6. Chemical and biological testing of water used in renal dialysis and other applicable tests based upon regulations, manufacturers’ recommendations, and organization experience.

Review of these standards demonstrates the importance of clinical engineering processes in improving patient safety and reducing the likelihood of patient injury resulting from a medical device.

JCAHO introduced the concept of sentinel event reporting in 1998. The sentinel event requirements of the JCAHO are found in the performance improvement standards. Accredited organizations are required to investigate sentinel events, which are to be analyzed from a systems perspective by the health care organization. “A sentinel event is an unexpected occurrence involving death or serious physical or psychological injury, or the risk thereof. Serious injury specifically includes loss of limb or function. The phrase, ‘or the risk thereof’ includes any process variation for which a recurrence would carry a significant chance of a serious adverse outcome.” The sentinel event is then subject to a root cause analysis.

“Root cause analysis is a process for identifying the basic or causal factors that underlie variation in performance, including the occurrence or possible occurrence of a sentinel event. A root cause analysis focuses primarily on systems and processes, not individual performance. It progresses from special causes in clinical processes to common causes in organizational processes, and identifies potential improvements in processes or systems that would tend to decrease the likelihood of such events in the future, or determines, after analysis that no such improvement opportunities exist.” JCAHO requires an action plan that identifies the strategies the organization intends to implement to reduce the risk of similar events occurring in the future. (See http://www.jcaho.org/accredited+organizations/hospitals/sentinel+events/se_pp.htm)

In addition to the self-investigation requirement, the JCAHO has a sentinel event advisory group that reviews data and decides whether to issue an alert and develop a related patient safety goal. If an alert or patient safety goal is developed and published, all accredited facilities are expected to review the information and take the necessary action to improve patient safety.

Of the 25 JCAHO safety reports available, seven have a direct impact on the activities of clinical engineers:

1. *Preventing Surgical Fires*, June 24, 2003
2. *Bedrail-related Entrapment Deaths*, September 6, 2002
3. *Preventing Ventilator-related Deaths and Injuries*, February 26, 2002

In addition to the accreditation requirements, the JCAHO has begun setting national patient safety goals. Two of the seven 2004 JCAHO National Patient Safety Goals are relevant to clinical engineering:

1. “Improve the safety of using infusion pumps by ensuring free-flow protection on all general use and patient controlled analgesia intravenous infusion pumps.”
2. “Improve the effectiveness of clinical alarm systems by implementing regular preventive maintenance and testing of alarm systems. Assurance that alarms are activated with appropriate settings and are sufficiently audible with respect to distances and competing noise within the unit.”

Although JCAHO is the primary accrediting body for health care organizations, there are additional accrediting bodies that address patient safety and medical device safety. Other significant accrediting organizations include:

- The Accreditation Association of Ambulatory Health Care accredits all types of ambulatory care providers, including office based surgical practices, urgent care centers, and lithotripsy centers.
- The Commission on Accreditation of Rehabilitation Facilities accredits rehabilitation facilities, adult day care services, assisted living facilities, behavioral health organizations, community service organizations, and employment training and service organizations.
- The Community Health Accreditation Program accredits community nursing centers, community rehabilitation centers, home care services, home infusion therapy programs, and home medical equipment providers.

Summary

Risk managers are, by nature, a skeptical group, assuming the worst. That is, if something can go wrong from a design, systems, staffing, training, or misuse perspective, it will. There are many activities in which clinical engineers participate that can help the risk manager sleep at night, if these activities are managed and communicated to the risk manager consistently. Clinical engineering risk issues that have come to the forefront of health care risk managers in recent years include the following:

- Device recalls
- Devicetracking requirements
- Device-incident investigations using root cause analysis
- Device procurement using Failure Modes and Effects Analysis (FMEA)
- Clinical department technology risks, such as:
 1. Critical alarms
 2. Neonatology
 3. Lasers
 4. Hemodialysis
 5. Anesthesia
- Reuse of devices
- Alternate parts and supplies
- EMI interference
- Disposal of used equipment
- In-house repair and device modifications

- Off-label, off-shelf, and unapproved uses of devices
- Patient- or physician-owned equipment
- Borrowing and lending equipment

Other areas where clinical engineers can contribute to risk management include lasers and anesthesia and other gases. The clinical engineer can make significant contributions to the selection, safety procedures in use, and continuing safe operation of surgical and ophthalmologic lasers. While some lasers may be handled by laser technicians or the manufacturer, it is important for a trained professional within the organization to have a close working knowledge of the devices in case an adverse event may be related to them.

In addition, problems in administering the proper gas and in eliminating known waste gases have resulted in significant risk and losses to health care organizations. In some organizations, the responsibility for such issues rests with facilities engineering. In other organizations, partial or complete responsibility for medical gases and their waste elimination rests with the clinical engineer. Initial and routine testing of medical gases and the effectiveness of their elimination methods are recommended. Testing gas elimination methods following any work performed on the systems can help control risk.

If clinical engineers acknowledge these significant risks and communicate with the risk manager to identify the policies and procedures for minimizing risk in these areas, the risk manager will sleep better at night and patients will be safer.

Risk management is every employee's responsibility. Each employee performs risk management tasks every day, although they may not often be aware of this important function, nor may they given credit for their contributions to patient safety. From a clinical engineering perspective, identification of potential or actual problems with equipment, adherence to regulations, and reporting and investigation of incidents are all risk management functions.

Further Information

The following is a list of government and professional organizations that include patient safety issues of interest to clinical engineers. This list is not all-inclusive nor does inclusion in this list connote endorsement by the authors of this chapter.

Agency for Health Care Research & Quality (AHRQ). www.ahrq.gov/qual/errorsix.htm This site shows AHRQ's involvement with patient safety through links to press releases, documents, speeches, statements, and hearings.

Morbidity and Mortality Rounds on the Web: This web-based patient safety resource and journal features monthly expert analysis of five cases of medical errors in the areas of medicine, surgery/anesthesia, obstetrics-gynecology, pediatrics and "other." The site also links to interactive learning modules, forums for online discussion, and resources links. American Academy of Orthopaedic Surgeons (AAOS). <http://orthoinfo.aaos.org/>

Association site contains information on orthopaedic conditions and treatments, injury prevention, and wellness and exercise, along with fact sheets on patient safety surgery issues.

American Association of Nurse Anesthetists (AANA). www.anesthesiapatientsafety.com Patient safety site focuses on general nurse-anesthetist information and includes articles relating to patient communication, conscious sedation, and standards for anesthesia safety.

American Hospital Association (AHA). http://www.aha.org/patientsafety/safe_home.asp Includes information on AHA's initiatives, and focuses on medication safety and safety culture. Resources include links to successful practices, reporting information, the Strategies for Leadership series in PDF format, and links to major reports.

American Medical Association (AMA). NPSF's Web site (www.npsf.org)

Includes information on patient safety and AMA guidelines.

American Nurses Association (ANA). Occupational Safety: www.ana.org/dlwh/osh Focuses specifically on occupational health, including articles on needles sticks and links to OSHA and similar organizations.

Anesthesia Patient Safety Foundation (APSF). www.apsf.org Devoted to patient safety, this site provides a video library, newsletters, research grants, links to other web sites, questions and answers, and a protocol for adverse events.

Association for the Advancement of Medical Instrumentation. www.aami.org Dedicated to increasing the understanding, safety, and efficacy of medical instrumentation, this site includes industry standards, forums, and newsletters.

Association of Health care Risk Management (ASHRM). www.ashrm.org

Devoted to health care risk management, links to related sites, forums, newsletter

Association of Perioperative Registered Nurses (AORN). www.patientsafetyfirst.org Information for nurses; patient section of this site provides materials on safety before, during, and after surgery.

Association of Professionals in Infection Control and Epidemiology (APIC). www.apic.org/safety This site includes information on a patient safety training course titled Patient Safety: Tools for Implementing an Effective Program, an overview resource entitled the *Patient Safety Backgrounder*, and a tool entitled *Effective Strategies for Improving Patient Safety*.

American Society of Anesthesiologists (ASA). www.asahq.org This site links to several potential resources in anesthesia safety (including videos). Department of Defense (DOD). www.afip.org/PSC (Patient Safety Workgroup) This site contains information on the center for patient safety in the DOD, which is geared toward identifying systemic errors in the military and includes patient safety newsletters..

Emergency Care Research Institute (ECRI). www.mdrs.ecri.org (Medical Device Safety Reports) ECRI provides a range of tools and resources related to patient safety and health care quality, particularly focusing on devices and technology.

Food and Drug Administration (FDA). www.fda.gov/cder/drug/MedErrors/default.htm (Center for Drug Evaluation & Research) Associated with medical device errors, directions for reporting an error (www.fda.gov/medwatch/), and federal guidelines.

Institute of Medicine (IOM). <http://www.iom.edu/IOM/IOMHome.nsf/Pages/Quality+Initiative> Includes current and past reports and studies related to quality of care and patient safety.

Joint Commission on Accreditation of Healthcare Organizations (JCAHO). www.jcaho.org Information regarding standards, standards development, sentinel events, and legislative issues if available on this site.

Leapfrog Group. www.leapfroggroup.org Includes information on the Leapfrog Group's approach and information and fact sheets on three initiatives, including computer physician order entry, evidence-based hospital referral, and ICU physician staffing.

National Quality Forum (NQF). www.qualityforum.org Includes information regarding NQF's on-going projects and reports in patient safety, as well as links to completed reports.

Patient Safety Institute (PSI). www.ptsafety.org Includes information on this organization, which strives to work with hospitals, providers and patients to reduce medical error through the use of technology and the building of relationships.

Premier, Inc. <http://www.premierinc.com/safety/> Includes resources for patients and health care professionals; Safety Share electronic newsletter is archived on website and an online store offers many free safety resources.

Risk Management Foundation (RMF). www.rmf.harvard.edu/patientsafety (Center for Patient Safety) Includes information on risk management, patient safety, and other related resources.

The Institute of Electrical and Electronics Engineers. www.ieeeusa.org Includes standards and provides a forum for medical device engineers.

Veteran's Administration (VA). www.patientsafety.gov (National Center for Patient Safety) Includes resources in patient safety, information on culture of safety, root cause analysis, a glossary of terms, a discussion room, and a library.

Patient Safety Best Practices Model

Paul Vegoda
Manhasset, NY

Carl Abramson
Malvern Group
Malvern, PA

Patient safety has become the watchword of patient care in the first years of the 21st century. This is the result of the often-quoted report of the Institute of Medicine (IOM) on patient injuries (Kohn et al., 2000). According to another report (AHRQ, 2001), 700,000 patients are victims of medical errors every year.

Patient safety does not just happen. It takes careful analysis, planning, and effort. (See Chapter 55.) Improvement requires will because durable improvement is not an accident; it takes effort (Berwick, 2003).

Many health care organizations depend on analyzing reported incidents to determine what caused the incident and how to prevent that type of incident from reoccurring. (See Chapter 64.) Correcting reported problems, which have occurred at the patient's expense, is considered an acceptable approach to decreasing incidents. This retrospective approach presumes that a strong patient safety foundation is in place. It also assumes that corrective steps for making the equivalent of last minute adjustments to a close-to-perfect system results in an environment with acceptable risks.

A better approach however is to complete a proactive review of potential problem processes and then implement redesigned processes to prevent reportable incidents from occurring (Dolan, 2003).

Silver Bullet

The primary emphasis in health care has been to apply technology to the problem of patient safety. The authors believe that technologies such as bar coding, computerized physician order entry (CPOE), and clinical data repositories are excellent tools to support patient safety initiatives and also improve the quality of patient care, but they are not the silver bullets that will eliminate the medication errors that lead to adverse drug events (ADEs).

The causes of medication errors can be attributed to the following (Ten Key Elements of Medication Safety, <http://www.ismp.org>):

- Critical patient information missing
- Critical drug information missing
- Miscommunication of drug order
- Drug name, label, or, packaging problem
- Drug storage or delivery problem
- Drug delivery device problem
- Environmental, staffing, or workflow problem
- Lack of staff education
- Lack of patient education
- Lack of quality control or independent check systems

Although miscommunication of a drug order can be virtually eliminated by CPOE, robust clinical information systems must be tightly integrated with the CPOE use to reduce the occurrence of missing patient and drug information that is critical in determining an appropriate therapy (Bates and Gawande, 2003).

The first three causes of medication errors listed previously can be reduced by the use of CPOE and associated clinical information.

Automating order entry provides only a partial solution to reducing medication errors. Automation of a poorly designed process compounds the problem.

Process Analysis

The premise that technology alone is sufficient to eliminate medication errors must be replaced by the plans to conduct an analysis of existing processes and redefinition of workflow prior to the implementation of new technologies.

The analysis of existing processes will reveal the extent to which technology can support the reduction of medication errors and expose the need for critical remediation in areas not impacted by technology.

Modeling both the existing processes and published standards for best practice to determine potential high-risk processes (existing processes that can cause harm to a patient), allows the development of new processes to replace the high-risk processes. At this point, the new processes can take advantage of the technology tools available to support them.

As is evident from the Institute for Safe Medication Practices (ISMP) error categorization list previously described, errors can include problems in practice, products, procedures, and systems. A process is a combination of practice, products, procedures, and systems that completes a purpose (e.g., delivers a medication dose).

Patient safety is impacted by each of these hospital domains:

- Inpatient
- ICU
- ED
- OR
- Outpatient
- Ancillary services
- Administration

In each of these domains, individuals provide information, make decisions, and take actions to carry out medication-administration processes. These individuals include the following:

- Patients (provide history)
- Attending physicians (determine therapies)
- House staff (monitor patient progress)
- Nurses (administer medication doses)
- Pharmacists (check medication order for appropriate medication)
- Ancillary technicians (record test results)

Given the interaction of many elements, the processes that ultimately affecting the medication of a patient must be modeled and analyzed systematically for potential risk. Special attention must be given to variations in processes throughout different domains.

The methodology described by the authors is based on process-modeling techniques that were developed for Health Insurance Portability and Accountability Act (HIPAA) assessments, which provided significant findings about process problems far beyond the scope of HIPAA requirements. (See Chapter 104.) Those findings are discussed below.

Methodology

The methodology developed is based on three fundamental premises:

- An organization must know how its processes work..
- Variability in processes must be reduced..
- Repeatable processes must be implemented.

While these premises may seem fundamental, they are not necessarily practiced by many organizations. The methodology creates a baseline model of an organization's existing processes, which can be measured against the Patient Safety Best-Practices Model developed by the authors.

The Patient Safety Best-Practices Model was developed based on Joint Commission on Accreditation of Healthcare Organizations (JCAHO) patient safety goals and accreditation requirements, National Coordinating Council for Medication Error (NCCMERP) and American Society of Health System Pharmacists (ASHP) guidelines, ISMP, and others. These guidelines and requirements were combined to provide a best practices model that will provide the basis for the assessment of current practices.

The Patient Safety Best-Practices Model is an evolving model, which is updated as new standards, and requirements are published. The model represents the best thinking of the analysts, physicians, nurses, and pharmacists who are working with the authors.

The initial step in the methodology is data collection. Data collection is a multistep process that involves two distinct sub-processes; direct interviews of nurses, pharmacists, and physicians and an anonymous staff survey on patient safety. The use of an anonymous survey is critical to the success of the patient safety data gathering, since some punitive health care cultures tend to discourage the reporting of medication errors. While these unreported errors might not necessarily lead to an ADE in any particular instance, there could be a fatality if the processes that lead to the particular practice are left unchanged. In the experience of the authors, some health care organizations report extremely low medication error rates have a low rate of internal reporting due to a culture that punishes honesty and discourages the reporting of errors to management.

Concurrent with the data collected by the interviews, models of the processes described by the interviewees are built using ProcessMapper®, a proprietary model-building software system. Figures 57-1 and 57-2 show examples of ProcessMapper® output in both text format (Figure 57-1) and graphical representation of the process (Figure 57-2).

Concurrent with the development of the organization's current process model is a review of current policies, procedures, and forms. This review is necessary to determine whether current policies meet best-practice and accreditation requirements.

If policies meet requirements, a review of how the processes are implemented is critical since implementation of processes may differ from policy requirements.

Patient safety committee minutes and incident-reporting logs are studied to determine the types of incidents that were reported in the past and the processes that were developed to prevent reoccurrences of the incident. The anonymous survey will fill in the gaps in the patient safety committee minutes and the incident-reporting logs.

After the data are gathered and the current process models are built, an analysis of the gaps between the Patient Safety Best-Practices model and the current process model is completed. This analysis determines potential risks from the continuation of current practice and provides a series of recommendations, which will bring the current processes into compliance with the recommended best practices.

A report is prepared which lists the recommended best practices, the current processes in place, the risk, if any, associated with current processes, and recommendations for compliance.

Patient Safety Best-Practices Model

- 4. Improve Medication-Administration Process
 - 4.1 Establish policy for identifying and managing sentinel events
 - 4.2 Establish policy for internal reporting
 - 4.3 Establish policy for medication-administration process
 - 4.3.1 Establish policy for enforcement of medication-administration standards
 - 4.3.2 Establish policy for staff education about medication administration
 - 4.3.3 Establish policy for labeling medications dispensed to patients
 - 4.3.3.1 Ensure that medication-labeling policy promotes safe use of medication
 - 4.3.4 Establish policies for preparation of drugs

Figure 57-1 Sample of patient safety best-practices model text.

The methodology can be summarized as follows:

- Build a model of current medication-administration processes.
- Review any process changes implemented due to past events.
- Compare the model of current processes to the Patient Safety Best-Practices model.
- Assess the gaps between current processes and the recommended standards.
- Develop a plan to close gaps.

Results of Process Modeling

The process-modeling methodology described above was originally developed to provide a cost-effective approach to assess the impact of the HIPAA regulations on the operations of health care providers (Vegoda and Abramson, 2003). Process models of the HIPAA Privacy

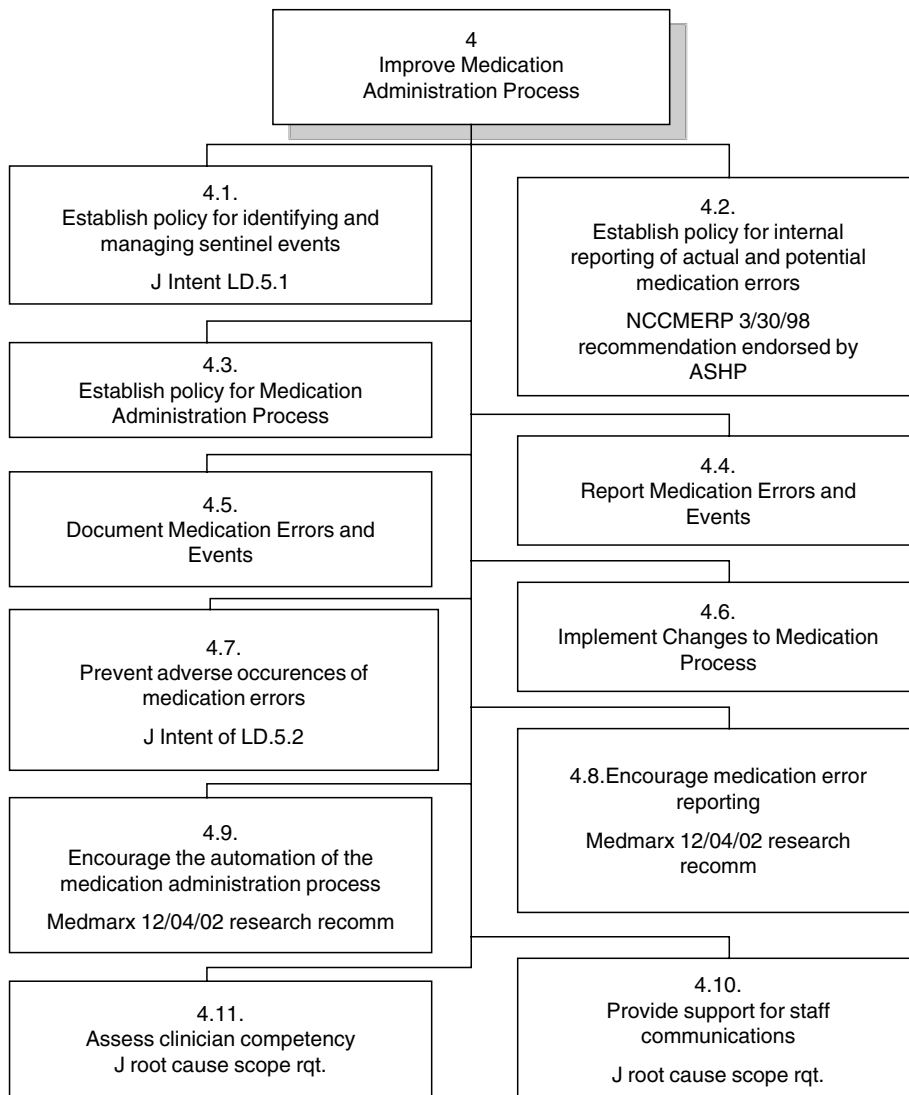

Figure 57-2 Graphic representation of patient safety best practices model.

and Security regulations were built. (See Chapter 104.) The use of the ProcessMapper© system facilitated the update of the regulations models as the original requirements changed.

Staff members were interviewed so that a model of the processes that were currently in place could be built. After the staff members who had been interviewed confirmed the correctness of the model, it was assessed against the privacy and security models and the gaps relative to HIPAA compliance were determined and documented. Compliance recommendations were developed based on the gaps. These recommendations suggested changes to current processes or the implementation of new processes required to comply with the regulations.

Policy models were built based on HIPAA requirements since HIPAA compliance requires that every process be documented with policies and procedures. The current policies were compared to the models to determine policy gaps. Modifications to existing policies and implementation of new policies were recommended as the result of the comparison.

Concurrent with the development of the process models, the ProcessMapper© provides for the documentation of observations and recommendations.

Numerous non-HIPAA related observations and recommendations resulted from the process modeling methodology. In a number of instances, management had no idea of the processes that were being followed by the staff until they reviewed the process models.

Time Bombs

Some examples of problems that were uncovered during proactive process data collection for process-model building are listed here.

A pharmacist prepared the morning delivery medication carts in the evening before leaving the hospital. The next morning, the pharmacist added any orders to the cart that came in during the night. The pharmacist delivered the carts to the nursing units by the required time of 8:00 a.m. As part of the model building interview, the pharmacist was asked if the orders that came in during the night were checked for drug–drug interactions or drug allergies. The reply was that there was no time to do the checks if the carts were to arrive on time. The checks could be completed post-administration.

A review of the hospital's policies showed that there was a requirement for the pharmacy to complete drug–drug interaction and drug allergy checks prior to dispensing any medication. Although the policy requirement was in place, the process being performed

by the pharmacist was not the process that management believed was in use. The use of proactive process modeling unveiled this very high-risk process.

A second example of how process modeling can uncover potential high-risk processes involved the modeling of nursing practice. Many hospitals have implemented 12-hour nursing shifts for 3 days. During the modeling process, it was determined that the hospital being assessed had its nurses work three 12-hour shifts while the nursing supervisors worked five 8-hour shifts so that there was continuity of supervision over the work week.

As a result of the difference of shift hours, two different supervisors supervised a nurse during the nursing shift. Building the process model led to the discovery that the different shift supervisors required different processes for a given practice. This caused confusion among the nursing staff and a huge variability of practice. One supervisor followed approved hospital policies and procedures, while the other established processes that were not known to the hospital clinical management.

While either of the processes modeled might accomplish the required outcome, the risk lay in the variability demanded by the nursing supervisors.

These examples demonstrate that proactive analysis of processes can reveal hidden features of the medication administration process that may harm patients. Also, a proactive analysis of the medication administration process comparing actual processes to accreditation requirements and best-practice recommendations can go a long way toward identifying the process gaps that can cause harm.

Hospital Safety Programs

Matthew F. Baretich

President, Baretich Engineering, Inc.
Fort Collins, Co

Safety and effectiveness have long been watchwords for clinical engineers. Medical devices should do what the health care practitioner wants them to do (effectiveness) and not do what the practitioner does not want them to do (safety). These are the two sides of the coin of clinical engineering. This chapter looks at the safety side of the coin. However, it does not focus directly on medical device safety—those topics are thoroughly addressed in other articles in this handbook. Instead, it describes the broader context of safety programs throughout the hospital. To be most effective, the safety-related aspects of clinical engineering practice must be integrated into these hospital-wide safety programs.

JCAHO Environment of Care Standards

The *Comprehensive Accreditation Manual for Hospitals* (CAMH) published by the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) includes a chapter entitled, “Management of the Environment of Care.” The standards contained in this chapter require hospitals to develop management plans in seven areas:

- Safety management (Standard EC.1.1)
- Security management (Standard EC.1.2)
- Hazardous materials and waste management (Standard EC.1.3)
- Emergency management (Standard EC.1.4)
- Life safety management (Standard EC.1.5)
- Medical equipment management (Standard EC.1.6)
- Utility systems management (Standard EC.1.7)

Each of the standards cited has associated standards that provide details regarding implementation of the management plans. For example, Standard EC.1.6 requires hospitals to develop a medical equipment management plan. Standard EC.2.6 requires hospitals to implement the medical equipment management plan. Standard EC.2.10.3 requires medical equipment used in hospitals to be maintained, tested, and inspected. Table 1 illustrates the relationships among the JCAHO Environment of Care standards.

Also illustrated in Table 58-1 are three other components of the JCAHO Environment of Care standards:

- Orientation and education (Standard EC.2.8)
- Other environmental considerations (Standards EC.3.1 through EC.3.4)
- Measuring outcomes of implementation (Standards EC.4.1 through EC.4.3)

The Safety Committee

Each JCAHO Environment of Care standard includes a set of intent statements that describe critical aspects of the standard. For example, Standard EC.1.1 requires hospitals to establish a safety-management Plan that includes specific components listed in the intent statements. One of the intent statements in Standard EC.1.1 requires a hospital's safety management plan to identify processes for examining safety issues by appropriate hospital representatives. Details regarding the role of this group, which has traditionally been referred to as the safety committee but is now often called the environment of care committee, are included in Standard EC.4.2.

Table 58-1 JCAHO Environment of Care Standards

	<i>Introduction (not scored)</i>	<i>Safety</i>	<i>Security</i>	<i>Hazardous and waste materials</i>	<i>Emergency management</i>	<i>Fire prevention</i>	<i>Medical equipment</i>	<i>Utility systems</i>	<i>Orientation and education</i>
Planning	EC.1	EC.1.1. EC.1.1.1 EC.1.1.2	EC.1.2	EC.1.3	EC.1.4	EC.1.5 EC.1.5.1	EC.1.6	EC.1.7 EC.1.7.1	
Implementation – general	EC.2	EC.2.1	EC.2.2	EC.2.3	EC.2.4	EC.2.5	EC.2.6	EC.2.7	EC.2.8
Implementation – drills	EC.2.9				EC.2.9.1	EC.2.9.2			
Implementation – maintenance	EC.2.10	EC.2.10.1				EC.2.10.2	EC.2.10.3	EC.2.10.4 EC.2.10.4.1	
	<i>Introduction (not scored)</i>	<i>Application</i>							
Other environmental considerations	EC.3	EC.3.1 EC.3.2 EC.3.2.1 EC.3.3 EC.3.4							
Measuring outcomes of implementation	EC.4	EC.4.1 EC.4.2 EC.4.3							

The JCAHO refers to the safety committee as a multidisciplinary improvement team. The activities of the safety committee, as described in Standard EC.4.2, include the following:

- Analyze of safety issues in a timely manner
- Develop and approve of recommendations
- Communicate of safety issues to the leaders of the hospital, to individuals responsible for performance-improvement activities, and, when appropriate, to relevant components of the hospital-wide patient safety program
- Communicate of recommendations for one or more performance improvement activity to the hospital's leaders at least annually

Typically, the clinical engineering department of the hospital is represented on the safety committee. It is appropriate, but less common, for the clinical engineering representative to serve as chairperson of the committee.

The safety committee serves as a forum for reports from the seven environment of care areas. For example, the safety committee will receive reports as specified in the hospital's Medical Equipment Management Plan, including performance monitoring data and incident investigation reports. Serving as a reporting forum is an essential role of the safety committee. However, the great value of the safety committee is found in its ability to subject these reports to multidisciplinary analysis. Careful analysis from a range of perspectives will produce communications, recommendations, and performance-improvement activities that enhance safety throughout the hospital.

The Safety Officer

The JCAHO Standard EC.1.1 requires a hospital's safety management plan to designate "a qualified individual(s) to oversee development, implementation, and monitoring of safety management." To carry out these responsibilities, most hospitals formally designate an individual to serve as safety officer. Standard EC.1.1 also mandates an "individual(s) to intervene whenever conditions pose an immediate threat to life or health or threaten damage to equipment or buildings." This authority is typically granted at least one member of the hospital staff, including the safety officer.

In many hospitals, the safety officer serves as chairperson of the safety committee. However, it is also common to separate these functions, so the safety officer serves as a member of the safety committee but not as its chairperson. In smaller organizations, the safety officer may be given responsibility for not only the safety management plan but also other environment management plans such as those for life safety management, management of hazardous materials, and waste management. In a relatively small number of hospitals, clinical engineers serve as safety officers. This represents an appropriate opportunity for career development for hospital-based clinical engineers.

A critical aspect of the safety officer's role is the collection and reporting of information regarding the hospital's environment of care. Details regarding these activities are included in Standard EC.4.1. It is important to note that JCAHO expects the safety officer to review information from all environment of care areas. For example, the standard states that the safety officer "reviews summaries of deficiencies, problems, failures, and user errors related to . . . managing medical equipment." Thus, the safety officer is in a position to coordinate information across the entire range of JCAHO environment of care issues.

Environment of Care Management Plans

Management plans serve as executive summaries of how a hospital meets the intent statements for each environment of care standard. Each management plan should include a statement of objectives. As a hospital defines the objectives for a particular management plan, it is important to be consistent with the objectives that JCAHO incorporates into its environment of {See hyphenation query} care standards. For example, Standard EC.1.6 states that the medical equipment management plan should "promote the safe and effective

use of equipment." Thus, the medical equipment management plan is *not* a description of how the clinical engineering department functions; it is a description of how the hospital meets the intent statements under Standard EC.1.6.

To continue this example, the standard requires the management plan to establish emergency procedures regarding "when and how to perform emergency clinical interventions when medical equipment fails." This is generally a responsibility assigned to patient care components of the organization, such as nursing services, rather than to clinical engineering. However, this responsibility should be addressed in the medical equipment management plan and it should be considered as a component of the hospital's environment of care program.

Each management plan also should include a statement of the scope of the plan. In general, the scope of a hospital's environment of care program should cover all facilities in which the hospital's patients receive care, and all facilities in which the hospital's employees work. The scope statements for particular management plans may build on this fundamental definition. For example, the scope statement for a hospital's medical equipment management plan might specify the places in which medical equipment is used (e.g., main hospital, offsite clinics, home care) or categories of medical equipment that the hospital manages in different ways (e.g., imaging equipment maintenance managed by radiology, general medical equipment managed by clinical engineering). However, the scope statement is written for a particular management plans, it must cover the full range of responsibilities for the hospital and not only those for an individual department.

Following the statements of objectives and scope, each environment of care management plan should address all intent statements in the relevant standards. It is useful to include the actual intent statement and to follow it with a brief description of ways in which hospital meets the intent. Describe who does what with regard to the intent statement in a few sentences. This description should be followed by references to detailed policies, procedures, and documentation that the reader may pursue for further information.

As a hospital develops its environment of care management plans, it should carefully examine each activity for completeness. First, does the activity fully meet the intent of the standard? Second, does the activity contribute to achieving the stated objectives for the management plan? Third, does the activity address the entire scope of the management plan? The management plan is complete only when all of these questions can be answered affirmatively.

The Performance Improvement Cycle

Performance improvement is a fundamental concept underlying all JCAHO standards. This is a continuous process of monitoring and evaluating performance to identify and realize opportunities for improvement (JCAHO, 2001). Figure 58-1 illustrates the performance improvement cycle for the environment of care standards.

Each environment of care management plan is required to establish a process for ongoing monitoring of performance. Typically, each management plan will specify a small number of "performance monitors" that measure critical aspects of performance under the plan. For example, the medical equipment management plan may specify periodic monitoring of the percentage of scheduled maintenance procedures that are completed on schedule (See chapter 50). When specifying a performance monitor, it is important to define how it is calculated (e.g., mathematical definitions of the numerator and denominator), how often it is calculated (e.g., monthly), how it is reported (e.g., quarterly to the safety committee), and whether a target value has been determined (e.g., 95% based on JCAHO scoring standards for Standard EC.2.10.3).

Each environment of care management plan is also required to describe "how an annual evaluation of the . . . program's objectives, scope, performance, and effectiveness will occur." When describing the annual evaluation process, it is important to define who conducts the evaluation (e.g., a task force of the safety committee), what process is followed (e.g., review of performance monitoring data for the preceding 12 months), and how the findings are reported (e.g., through the safety committee to administration). Reporting requirements are addressed in Standard EC.4.2.

The results of the annual evaluation may be used to modify the environment of care management plans. For example, if a particular activity does not adequately address the

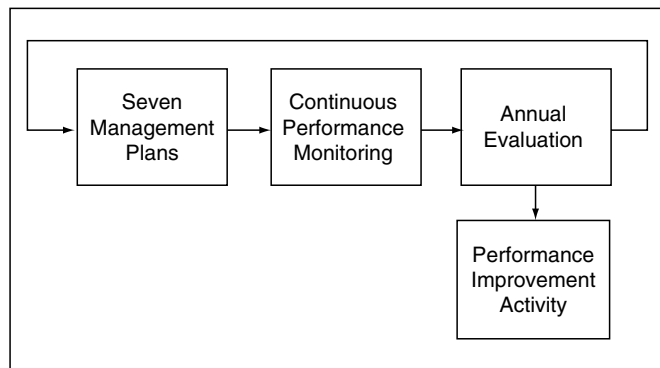

Figure 58-1 Performance improvement cycle for the environment of care standards.

entire range for which it is applicable, the activity may be expanded to cover the full scope as defined for that management plan. The results also may be used to modify the performance monitors that are specified in the management plans. For example, review of medical equipment management data may suggest the need to monitor the failure rate of a particular type of medical device.

Components of Hospital Safety Programs

The performance-improvement cycle links the safety committee, the safety officer, and the managers of the seven environment of care management plans into a framework for coordinating the many separate activities that constitute a hospital-wide safety program. Key components of the safety program are described as follows.

Safety Management

One of the most widely-recognized activities under the safety-management program is the performance of hazard-surveillance rounds on a regular basis (Standard EC.2.10.1). Although these rounds may be conducted by one or two people (e.g., the safety officer and the manager of the unit under surveillance), it is often more effective to broaden the objectives of the process and include other personnel in a small hazard-surveillance team. Additional participants may be drawn from infection control, environmental services (housekeeping), facilities engineering, and clinical engineering. Although these additional participants may focus primarily on their own areas of responsibility, they also can provide complementary perspectives for other members of the team.

Hospitals are also required by JCAHO to establish worker-safety programs (Standard EC.1.1.1). Typically, such programs are based on Occupational Safety and Health Administration (OSHA) regulations and other related government regulations. Protection from hazardous materials is a prominent issue for all health care workers (Standard EC.1.3). Protection from blood borne pathogens (e.g., hepatitis B virus) and airborne pathogens (e.g., tuberculosis bacteria) is of particular concern to clinicians. Other requirements, such as lockout-tagout programs, are applicable to workers in clinical engineering and facilities engineering.

Emergency Management

JCAHO recently expanded the scope of its emergency management standards to include four phases of activity: Mitigation, preparedness, response, and recovery (Standard EC.1.4). The involvement of clinical engineers is valuable in all phases, particularly with regard to the role of medical and other technologies in managing emergency situations.

Life Safety Management

JCAHO and most fire-safety jurisdictions require hospitals to comply with the life safety code NFPA 101 of the National Fire Protection Association (NFPA), published in 1997. This standard provides detailed specifications for design, construction, and operation of buildings to protect occupants from fire. JCAHO has developed a Statement of Conditions (SOC) document that hospitals must use to verify compliance with the life safety code (Standard EC.1.5.1). When deficiencies are identified, hospitals must document each deficiency and specify a plan of corrective action in Part 4 of the SOC referred to as a plan for improvement, and, as appropriate, implement interim life safety measures (Standard EC.1.5) to mitigate the deficiencies.

Hospitals are also required to conduct and evaluate fire drills at regular intervals (Standard EC.2.9.2) and to prohibit smoking in hospital buildings except under strictly-controlled circumstances (Standard EC.1.1.2).

Medical Equipment and Utility Systems Management

In the JCAHO standards, many parallels exist between the medical equipment management program (Standard EC.1.6) and the utility systems management program (Standard EC.1.7). In both cases, critical devices and systems are identified for inclusion in a pro-

gram of scheduled inspection, testing, and maintenance. A well-designed program contributes to both the safety and effectiveness of patient care.

JCAHO has continued to expand the scope of utility systems management to include infection control (Standard EC.1.6), particularly for waterborne pathogens (e.g., legionella bacteria) and airborne pathogens (e.g., tuberculosis bacteria). Infection control has also become a prominent issue in facility design and construction (Standard EC.3.2.1) with the publication of the 2001 edition of *Guidelines for Design and Construction of Hospital and Health Care Facilities* by the American Institute of Architects (AIA). These infection control-related requirements have promoted greater cooperation between infection control professionals on one hand, and clinical and facilities engineers on the other.

Patient Safety

In 2000, the Institute of Medicine published *To Err is Human: Building a Safer Health System* (Kohn, 2000). This landmark report estimated that medical errors cause 44,000 to 98,000 deaths annually in hospitals in the United States. Although there is some controversy regarding the actual number of deaths caused by medical errors, there is a strong consensus that patient safety can and should be improved. There is also general agreement that improvements in patient safety will *not* come from blaming health care providers and exhorting them to do better. Instead, hospitals need to improve the systems in which patient care is provided.

At the heart of a systems approach to patient safety is coordination of all systems components—the patient, patient care providers, support personnel, medical technologies (e.g., devices, drugs, and medical and surgical procedures), and the environment in which patient care is provided (See Chapter 59). The systems approach includes proactive analysis to anticipate ways in which a system can fail. It also includes root cause analysis of actual failures. The objective of both activities is to improve the systems in order to make future failure less likely.

As of July 2001, JCAHO extensively revised its hospital accreditation standards to directly address patient safety. The fundamental revisions were made in the leadership chapter, which now mandates that “leaders ensure implementation of an integrated patient safety program throughout the organization” (Standard LD.5). Building on earlier requirements to conduct retroactive root cause analyses of sentinel events (Standard PI.4.3), JCAHO now requires hospitals to conduct proactive analyses to identify potential risks to patient safety (Standard LD.5.2). This approach to risk assessment is explicitly based on the principles of systems engineering.

Additional revisions to JCAHO standards in January 2002, included integration of Environment of Care activities into the hospital-wide patient safety program. Standard EC.4.1 assigns the responsibility for integration to the safety officer. Standards EC.4.2 and EC.4.3 address the flow of information from the environment of care program to the patient safety program. This is a clear indication of the vital role that environment of care activities have played in advancing patient safety.

Thus, improving patient safety has become a dominant theme for JCAHO and for the entire health care delivery system. The area of patient safety offers with vast potential for clinical engineers to use their skills in medical and nonmedical technology management, their close association with clinical and nonclinical professionals throughout the hospital, and their solid grounding in general and specialized principles of engineering science. (See Chapter 55.)

As described in *Enhancing Patient Safety: The Role of Clinical Engineering*, a White Paper published by the American College of Clinical Engineering, clinical engineers are in a unique position to make valuable contributions to patient safety (ACCE, 2001). Through the paper, ACCE committed itself to promoting the principles of systems engineering as part of the body of knowledge for clinical engineering practice. Development of such skills will augment the ability of clinical engineers to adopt prominent roles in this new era of patient safety.

Summary

Hospital safety programs—designed to protect patients, visitors, and staff—are practical applications of the medical dictum “First, do no harm.” They are fundamental in creating an environment in which effective patient care can occur. Since its earliest days, the profession of clinical engineering has addressed safety in the clinical environment. Working in cooperation with professional colleagues throughout the health care delivery system, clinical engineering can extend their admirable record of contributions to hospital safety.

Systems Approach to Medical Device Safety

Marvin Shepherd

DEVTEQ Consulting
Walnut Creek, CA

Health care is delivered through an assemblage of systems and minisystems. If a device-related minisystem of an assemblage fails to deliver its clinical benefit or delivers a physical insult to a patient, an incident investigation will begin. Information will be gathered, devices will be tested, and personnel will be interviewed. Some conclusions will be reached, and corrective actions will be taken. However, when the investigative process is discussed with in-house investigators, the process is frequently found to be incomplete, flawed, or biased. These deficiencies appear to be related to the infrequency with which most in-hospital investigators perform investigations, a lack of education and training in investigative techniques, and a lack of understanding of analytical methods for determining the cause(s) of an event.

A generic system's risk model has been developed for analyzing the performance of a minisystem. It provides the investigator with a mental model of the interacting components of the mini-system and provides a logical pathway toward the root causes of an adverse event. In addition, at the time of a minisystem failure, the model can be used as a checklist to assure that information about each component has been gathered and analyzed for its contribution to the event. Although errors still will be made in causal determinations, they will not be due to a forgotten or neglected component or condition.

Background

The medical community has only recognized that appropriately designed health care delivery systems, subsystems and processes are the best approach to reducing medical errors (Moray, 1994; Reason, 1990; Senders and Moray, 1991; Norman and Draper, 1986). In 1976, a system safety model was developed that could be applied to the failure of medical devices from the viewpoint of equipment maintenance (Shepherd et al, 1976; Shepherd and Shaw, 1976). Only later was the model expanded to identify factors that prevented a clinical benefit from being delivered to a patient or that delivered a physical insult (Shepherd, 1983; Shepherd and Brown, 1992). In 1989, a device-education model for nurses, based on this model, was presented at an FDA conference (Abbey and Shepherd, 1989). As risk and safety are opposite sides of the same coin, and as the major players in health care were moving away from safety concepts and toward risk concepts, the name of the model was changed from "systems safety model" to "systems risk model" (SRM) in 1997 (Shepherd, 2000). With recent advances in human error theory, systems analysis, and increased concerns for patient safety, the model was modified again in 1999 to better address the search for the root causes of adverse events and to suggest more effective methods to prevent recurrences of such events (Shepherd, 2000; Shepherd, 1999).

The Systems Risk Model (SRM)

The systems risk model is illustrated in Figure 59-1 and is presented from the viewpoint of the health care provider.

Description of the SRM

The large envelope of Figure 59-1 represents the health care provider, i.e., hospital, ambulatory care center, nursing home, or other patient care location. In the center of the large envelope is a gray, shaded area containing the terms "operator," "facility," "device," "environment," and "patient." This represents a generic, device-related minisystem that delivers a clinical benefit. Each of the five components leads to smaller envelopes. These smaller envelopes contain the subcomponents of the five major components. There are a total of 14 subcomponents in the SRM. The five major components are at the end of the delivery system where patients receive care. The subcomponents are part of the end of the system that supports the minisystems at the patient care end (Cook and Woods, 1994). The flaws found within the subcomponents could lead to a component failure, that is, lead the minisystem outside its expected performance boundaries, or they

could cause a physical injury to the patient. More complex SRMs can be constructed by adding more devices or more operators.

Flaws located within the subcomponents frequently can be traced to their origins, before they entered the clinical environment. For instance, a flaw in a device component may originate with its design and construction; a flaw in a facility component may originate during the planning and preconstruction phases; and a flaw in the operator component may originate during basic education and training. These factors are shown in Figure 59-1 as being outside the large envelope. The health care provider has an opportunity to minimize these flaws through careful examination of a component before it enters the care delivery environment. Once the component becomes active in the clinical environment, the provider has lost this opportunity and must manage the risks associated with any flaws that passed through the initial scrutiny.

Health care providers organize their facilities to deliver care to a specific patient population; heart transplants generally are not performed at substance abuse centers. The facility component is designed, the device component is selected, and the operator component is trained to accommodate the selected population. Patients who fall outside this population are placed at a different risk level, which must be considered when analyzing minisystem failures.

Definitions for the Subcomponents

The definitions for the subcomponents of the systems risk model are provided in Table 59-1, columns 1 and 2. Column 4 contains some general questions to pose during an investigation that may lead an investigator to flaws of the system, often referred to as root causes. Column 3 contains the person or group administratively responsible for that subcomponent at the time of an adverse event. The designation of a responsible group is useful to the health care provider. Such a group can assist in determining the root causes and in deciding where to establish defense barriers, i.e., the special shielding or relocation of EMI-sensitive equipment away from community transmitters, the use of focused pre-purchase device evaluations to reduce unpredictable device failures, and the use of patient data entry forms that screen for unusual patient characteristics.

The Direct and Root Cause(s) of Failure

Determining the direct cause of an adverse event provides a doorway to the root cause.

Direct Cause

The direct cause of failure as it applies to a device-related, minisystem is a deviation in expected performance of a component of the SRM that results in the minisystem performance falling outside of specified boundaries or that delivers a physical insult to the patient. If the operator component fails, it is not only considered a direct cause, but also an active cause. Identification of the operator component as the direct cause is not intended to suggest blame, but is simply a modeling mechanism to establish a doorway to the subcomponents and to root cause(s). The failure of a component is just the beginning of an investigation.

Root Cause

Flaws in a minisystem are the root causes of adverse events. Flaws may be obvious, but managed or ignored, or they may go unrecognized until an adverse event occurs. Prior to an adverse event, the identification of these flaws is part of a quality improvement program. Following an event, identification of flaws is the goal of the accident investigator.

Finding the Cause(s) of Failure

The performance boundaries of a minisystem are established by many factors, including the design of the device, clinical trials, professional standards, operator expertise, organi-

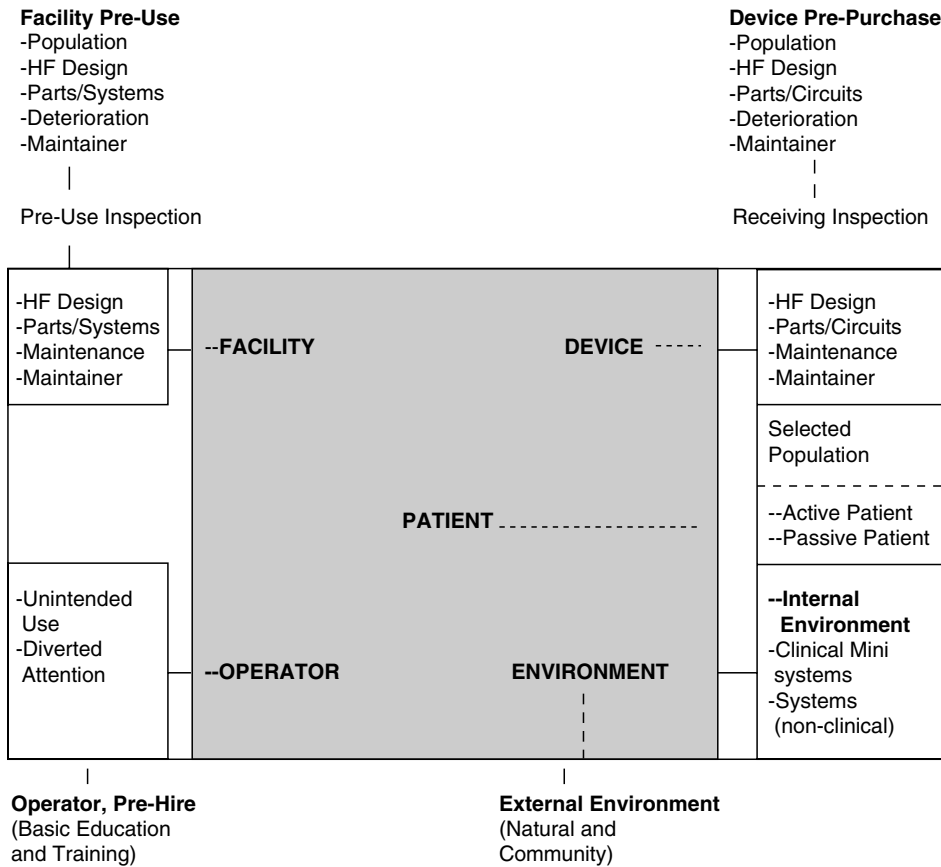

Figure 59-1 A systems risk model (SRM).

zational goals, policies and procedures, laws, and others. Finding the causes of failure requires the investigator to identify the component or components that exceeded the boundary limits. The search must begin at the site of injury, death or device malfunction, traced back to the SRM component(s), on to the subcomponent(s), and finally to the root cause(s). The fundamental mechanisms of injury and device malfunctions must be well understood by the investigator to begin the process properly.

Each component is examined to determine whether it deviated from expectations or can be excluded based on the conditions surrounding the event. It is typical to begin with an examination of the device to determine whether it meets the manufacturer’s performance and safety specifications. The same is true of the facility component. Both have objective specifications that can be readily measured. Any interactions between systems and minisystems must be assessed, and any characteristic of the patient that may have contributed to the event needs to be identified. The operator component is evaluated last and except for education and training, is it more difficult to assess.

Case Study of a Monitor That Failed to Alarm

A female adult patient with end-stage cancer was admitted to an emergency room (ER). She was subsequently placed in a private room, where vital signs were taken and a cardiac monitor was connected. The monitor was about 10 years old, and the heart rate alarms on this monitor had to be activated by pushing a button. The registry nurse did not activate the rate alarm because the nurse believed that default rate alarms activated automatically when the monitor power was turned on. The patient was visually monitored every 10-15 minutes. Approximately 90 minutes after the patient arrived and 10 minutes after being last examined, the patient was found dead. No heart rate alarms had alerted the nurse.

Investigating the Event

The following information was acquired during the investigation from numerous sources, including patient records, interviews, device examination and testing, and manuals.

- **Device Component.** The heart monitor itself and the 4-bed system were examined and found to function to the specification of the manufacturer. In this system, no default alarms occurred automatically when the power was on. Alarms would only function with a single, push-button activation.

- **Facility Component.** Although a noisy power line was considered as a possible source of noise that might turn off the alarms, it was rejected without any testing of the line.
- **Patient Component.** The patient was in the end stages of cancer and barely alert. Neither active nor passive characteristics were identified as contributing to the event. A “no code” had not been placed in the patient’s record.
- **Environment Component.** Other systems operating at the time, such as a radio system that was intermittently active and located within 6 feet of the foot of the bed, were considered and rejected as the source of the alarm failure.
- **Operator Component.** The operator of the monitor was a registered nurse (RN). Her education, training, and credentials were excellent for working in an emergency room. However, she was trained to use newer monitors that automatically set default limits when turned on. She had never worked with older monitors, such as the one in this case, that required a push-button to set the alarm.

Determining Direct Cause

In this instance, the hazard was the failure of the alarm to function in a timely manner. Although the patient would have died anyway, since a “no code” had not been entered into the patient’s record, a Code Blue team would respond if the alarm sounded. In evaluating each component of the system, all functioned normally except for the operator component. The operator simply failed to press the default alarm button. Using the SRM analysis, the operator was considered to be the direct cause as well as the administrative cause of the adverse event.

Determining Root Cause

The root causes of this event are rather interesting. One cause relates to the use of a mixture of monitoring systems of different designs. In some systems, default alarms are set automatically. In others, they are set with a push of a button. Neither the registry nurse nor the ER knew of these conditions. If either had known, the adverse event might not have occurred. If the ER had known the nature of the alarm and had failed to train all nurses to use it, the ER would have been negligent.

During investigational interviews, we encountered one regular ER nurse who said she knew that the monitor alarms were set automatically. She attempted to prove this by applying ECG electrodes to her body and inserting the ECG cable into a monitor. When her ECG was visible on the monitor, she lifted one of the electrodes from her body and an alarm sounded, but it was a leads-off alarm. The nurse did not know the difference between a leads-off alarm and a heart rate alarm.

TABLE 59-1 Definitions of Subcomponents and Administrative Responsibility

<i>Component/Subcomponent</i>	<i>Subcomponent definition</i>	<i>Administrative Responsibility at time of event</i>	<i>Generic questions related to root causes</i>
Device			
Human factors design	Design features defined by accepted human factors (HF), checklist guidelines or standards, or by the manufacturer.	Operator	Was the HF feature unusual? A new feature on a new device? A common feature on other devices? Different from devices with similar functions? Was it mentioned in the education and training curriculum? Mentioned in operator's manual? Was knowledge gained by the provider prior to hire? Was the human factors feature related to a device modification?
Parts/circuit design	Sudden and unpredictable failure of equipment, parts, or circuits	Manufacturer	Was unpredictability known prior to purchase? After purchase? Can one buy more reliable devices? Did the purchasing process examine other databases, such as FDA or ECRI, for similar problems? Does the maintenance database contain similar events with similar devices? Was there any indication that the unpredictable failure might be related to maintenance actions?
Deterioration	Slow and predictable changes in equipment accuracy, precision, and reliability	Device maintainer	Was device listed in inventory for PM? Was it scheduled for PM? Was PM performed? Did maintainer forget PM detail? Not enough maintainers to do PM? Budget cut prevented PM?
Maintainer	Action or inaction of maintainer resulting in equipment failure	Device maintainer	Could not repair device? Repaired same device multiple times? Maintainer never trained or educated to repair/PM this device? Received wrong information for repair? Not allowed enough time for repair? Distracted from repair? Under-trained in equipment repair (i.e., soldering or troubleshooting)?
Facility			
Human-factors design	Design features defined by human-factors (HF) guidelines or standards, or by the architects and engineers	Operator	Was HF feature unusual? New feature on new utility? Common feature on another utility? Different from utilities with similar functions? Was it mentioned in the ed/train curriculum? Mentioned in P&P orientation? Knowledge gained by provider prior to hire?
Parts/systems design	Sudden and unpredictable failure of facility parts or systems	Architect & engineer	Was unpredictability known before or after construction? Can one buy more reliable parts or systems? Did design process examine any databases for similar problems? Own? FDA? Colleagues? Does maintenance database contain similar events on similar devices? Any indication that the unpredictable failure might be related to maintenance actions?
Deterioration	Slow and predictable changes in the facility systems	Facility maintainer	Was utility/equipment listed in inventory for PM? Was it scheduled for PM? Was PM performed? Did maintainer forget PM detail? Not enough maintainers to do PM? Budget cut prevented PM?
Maintainer	Action or inaction of maintainer resulting in facility parts or systems failure	Facility maintainer	Could not repair system or equipment? Repaired same system or equipment multiple times? Maintainer was never trained or educated to repair/PM this system or equipment? Received wrong information for repair? Not allowed enough time for repair? Distracted from repair? Under-trained in basic repairs (e.g., soldering or troubleshooting)?
Patient			
Active			
educated	Patient who is knowledgeable of a hazard performs a harmful action	Patient	Is patient normal for this treatment area? Was patient knowledgeable of hazard? Was provider? Could device have been placed beyond patient's reach?
uneducated	Patient who is ignorant of a hazard or uncontrollably performs a harmful action	Operator	Should patient have been restrained? Sedated? Placed where they could be watched more carefully?
Passive	Patient condition or sensitivities	Operator	Was patient screened for sensitivities? Was sensitivity unusual? Should provider have known? Should this patient be treated at this provider's facility?
Operator			
Unintended use	Action or inaction due to lack of education or training that provides unintended results	Operator	Knowledgeable of this minisystem? Under trained/educated for this minisystem? Received orientation? Mentored? In-serviced? Operator manual missing?
Diverted attention	Action or inaction of educated/trained operator under certain circumstances that provides unintended results	Health care provider	Long hours? To many patients? Inadequate staff? Personal problems? Budget cuts? Excessive meetings? Did operator exceed the physical limits of an accessory or part?
Environment			
External	Unsafe or inefficacious device due to external systems outside the control of the health care provider	Nature or the community	Was the failure due to a natural disaster (i.e., earthquake, hurricane, or flood)? Normal environment of heat, sun, wind, and rain. Local disasters, (i.e., plane crash or utility failure)?
Internal	Unsafe or inefficacious device due to interaction with other systems or minisystems controlled by the health care provider	Operator	Caused by other clinical minisystems? Caused by utility systems? Telecommunications? Internal disaster, (i.e., a power failure that affects multiple patients)?

In this hospital, intensive care unit (ICU) nurses would occasionally work in the ER. We went to the ICU, which had only the new style of heart monitors, and interviewed four ICU nurses. Two of those nurses said that the default heart rate alarms on ER monitors were automatically set when the monitor power was turned on. This suggests that the nurse in question was simply the operator of a system that failed but the mistake could have been made by an ICU nurse as well. A literature search for similar events yielded at least two publications that warned of the possibility of errors when two systems that had with different methods for setting alarms were mixed. However, these warnings never filtered down to the registry nurse or the ER staff.

To prevent a future event, the ER added a label under each of the alarm buttons that directed nurses to push the button to activate the alarm. The hospital also updated nurse orientation training material and to the operating manual for the monitor itself with a note explaining the need to push a button to activate alarms. The hospital also developed a long-term plan to replace the older monitors.

One interesting aspect of this case is that if a "no code" had been placed on the patient's chart, no Code Blue response would have been necessary. The death of the patient would have been a non-event, and the failure of the nurse to set the alarms might have gone unnoticed. In addition, when the nurse checked the monitoring system to determine why the alarm had failed, she noted that the monitor clock was an hour behind real time. She said she believed that if the clock was wrong, the system must not have been functioning properly.

Summary

The SRM has been used for over 20 years to analyze device-related adverse events. It ensures that surrounding factors and pertinent conditions have been considered for their roles in the adverse event. It provides a logical pathway for pursuing patient injuries or system malperformance from an event to its root causes. The SRM identifies process locations where the health care provider can evaluate components to identify obvious flaws and prevent them from entering the clinical environment. Following an investigation, the SRM can also be used as a checklist to suggest changes in the minisystem that might prevent a recurrence of the event.

Interactions Between Medical Devices

Saul Miodownik

Director, Clinical Engineering, Memorial Sloan-Kettering Cancer Center
 New York, NY

The increasing complexity of medical instruments eventually causes conflicts between devices that are normally used on the same patient. Fundamental understanding of the technology and its relationship to specific aspects of the patient's anatomy and physiology is required to address potential interference with other devices.

As medical devices are deployed into various settings, including health care, their initial control and operation are often the responsibility of technical experts who are familiar with their nuances and quirks. By the time any technology is mature enough to be run effectively by appliance operators, that detailed knowledge is no longer needed and is often lost. Indeed, this is the normal evolution of most technology in society. Everyone uses televisions, DVD players, computers, and cellular phones with impunity, but few people are even vaguely conversant with the underlying technology that drives them.

Medical technology is no different in this regard. However fascinating the scientific and engineering underpinnings of a medical device may be, the end-user has no need to be aware of them. In isolation, this may be totally acceptable and, perhaps, preferable. Unfortunately, there are many instances when medical devices conflict with each other and can interfere with the correct diagnosis of a patient's condition or the delivery of the desired therapy. The responsibility increasingly falls on those who manage and purvey technological matters to analyze, anticipate, and ultimately prevent these interactions from negatively affecting the patient. In most settings, this vigilance and required knowledge become the responsibility of clinical and biomedical engineers.

Unanticipated medical device interactions have occurred at various levels for more than a century. Since the early days of the X-ray image, it has been known that some materials (often metallic) would affect the proper exposure of a diagnostic X-ray film. This was the direct consequence of ionizing radiation. Electrosurgical devices were in widespread use for decades before routine electrocardiogram (ECG) monitoring became a common anesthetic practice. The interaction between these necessary but conflicting technologies (much noise and, sometimes, temporary loss of the ECG signal during an X-ray) was immediately understood and accepted. The 1960s and 1970s raised a great deal of conjecture about, and fear of, lethal microshock as an undesirable consequence of the use of medical equipment and electrical appliances at the patient bedside. Although this danger never materialized, it did demonstrate that technology could interact in unexpected and potentially dangerous ways. (See Chapter 65.) The deployment of increasingly esoteric instrumentation can cause interactions between totally unrelated systems and can yield unpredictable consequences.

Perspectives

Very early in my experience as a clinical engineer, I was called to one of our intensive care units to check a cardiac monitor that was presenting an incorrect heart rate. From the central station, I observed the bed in question and what appeared to be a fairly reasonable low-voltage ECG. I confirmed the patient's heart rate reading of 160 BPM. The nursing staff told me that this could not be possible. After launching into an elaborate discussion of double-triggering and elevated P-waves mimicking R-waves, one of the intensive care unit (ICU) nurses said, "Excuse me, but he's been quite dead for over an hour!" I went into the patient's cubicle and looked around. The monitoring electrodes were still connected to the patient, as were the intravenous (IV) lines. I noticed that one of the IV lines ran through an infusion controller that was still turned on and delivering fluid to the patient. When the IV controller was turned off, the patient's ECG signal disappeared. At first I thought a radi-

ated pulse from the controller might be disrupting the ECG leads. Although I had no good explanation for this phenomenon at that time, the nurses thanked me for fixing the problem as I left. It was an episode that I never forgot (Miodownik, 2003).

EXAMPLE 1: The Van de Graff Generator Treadmill

In one case, the clinical engineering department was asked to configure a treadmill-based cardiac stress test system. There was an available automated treadmill that stepped through a preprogrammed elevation and speed sequence. We provided a spare ECG monitor that had a digital storage screen, heart rate meter, alarm limits, and strip chart recorder. The system was quickly assembled, configured, tested, and delivered to the ECG department in the autumn to everyone's satisfaction. Early in January of the very next year, we began receiving intermittent complaints of huge bursts of noise that distorted the ECG signal and ruined the test. The noise seemed to be related to the higher speeds of the treadmill, as it never occurred early in the stress test protocol. We investigated and discovered that the noise was the result of missing or incorrect pieces in the ECG A/D converter system. A direct recording from the analog ECG signal revealed no appreciable noise. We could find no defect in the monitor, or anything obviously wrong with the treadmill or its controller. Internal leads to the treadmill motors were fitted with the appropriate RF filter, as was the ECG cable. When the system was operated with a simulator, no noise was heard at any treadmill speed or elevation. Changing the monitor and the treadmill with different units that worked fine elsewhere still resulted in noise. The problem persisted, and led to the repetition of one or two stress tests per month.

By March of the same year, the complaints had subsided and finally disappeared. Throughout the summer, no further complaints came from the ECG Department. However, by winter they returned in force. This time, an able runner in our section volunteered to run on the treadmill for a stress test under our close scrutiny. Electrodes were placed, and the stress test protocol was conducted as for any patient. At a speed of about six miles per hour, dropped bits were in evidence on the screen. By the time the speed reached eight miles per hour, the ECG was unreadable, and the test had to be terminated. We repeated the problematic segments of the test but still could offer no explanation. We returned to the drawing board and pulled out the schematics of all of the affected instruments, and looked at them for clues. None appeared. We also wondered why the problem appeared to be seasonal.

Our hospital HVAC is particularly well-known for providing desert-like heat in the winter and a soggy form of cooling in the summer. At other times of the year, ambient climatic conditions usually prevail. We therefore wondered whether the static electrical charges that have a tendency to build up under very dry conditions might be related to this problem. In the final analysis, sudden discharge of static electricity was the proximal cause of the monitor problem. The etiology, however logical, was not obvious.

Patients who are scheduled for treadmill stress tests are asked to report for their test in comfortable running clothes and to wear sneakers or running shoes. After being prepped and outfitted with electrodes, they mount the treadmill and grab onto a handrail in front of them. The handrail has an insulating grip. This position was then maintained throughout the test. The interface between the treadmill running belt and the patient's sneaker sole behaved in the same manner as a Van de Graff generator. As the treadmill speed increased, electrons were stripped off the belt at an increasing rate. Since the patient was essentially electrically isolated from grounding (isolated ECG amplifier,

insulated sneakers, and insulated handrail on the treadmill), this system would charge the patient to ever increasing voltages. This continued unless the charge could leak away or until a sudden discharge of the accumulated electrons occurred. On more humid days, the charge-leakage rate through the air was sufficient to limit this voltage to low levels. On very dry days in the winter, the path of discharge was either through dielectric breakdown in the treadmill or through exceeding the isolation limits of the front-end ECG amplifier. Close inspection of the ECG amplifier schematic revealed a spark-gap discharge voltage limiter across the isolation barrier with a breakdown voltage of about 4000 volts. It was hypothesized that the sudden discharge of the spark gap sent enough voltage into the digital storage section of the monitor to cause the dropped bits. We revisited the treadmill with our runner and opened the ECG monitor to observe the activity when it was in use. Sure enough, at sufficient treadmill speed the spark gap was arcing and dropped bits obliterated the ECG trace. The solution to the problem was as simple as the etiology of the problem was complex. A 75-megohm resistor was placed across the spark gap to slowly drain off charge buildup while maintaining sufficiently high impedance for safety.

In this instance, a number of advanced design concepts failed because of the device interaction and potentially put the patient at risk. The isolation system was designed to ensure patient electrical safety; the digital storage and display of the ECG waveform was designed to provide easier viewing of the signal for immediate and accurate determination of ECG changes related to exercise; the spark gap was to protect the isolation system from potentially damaging voltages. It was precisely at the higher levels of exercise, when the most accurate reading of the ECG was needed, that the stress test system failed. However, this was no real failure; it was an interaction between medical devices (Elliott and Gianetti, 1995).

EXAMPLE 2: Blood Pressure High on Bubbles

Invasive pressure monitoring became common at the patient's bedside in the early 1970s. Pressure transducers required special domes that allowed coupling to the patient's vasculature via fluid-filled tubing. The nursing staff often complained that systolic pressure readings seemed high. They questioned these hypertensive pressure measurements and checked them against their pressure cuffs and stethoscopes. We would check the calibration of the pressure transducer and amplifier and pronounce them accurate. We would explain how the pressure module's digital display was surely more accurate than the nurse's meager attempt at blood pressure measurement by auscultation. However, their complaints persisted, and eventually were proven legitimate.

Invasive pressure measurement has now been in common use in critical care units and operating rooms for many years. With the advent of reliable, inexpensive, disposable pressure transducers and tubing sets, questions of accuracy, linearity, and repeatability have largely disappeared. However, the issue of fluid-filled tubing interacting with the pressure transducer and the monitor remains a thorny problem.

Most invasive pressure monitoring instruments extract diastolic, systolic, and mean pressure information by observing the waveform's minimum and maximum values and integrating the area under the waveform curve to extract its mean value. Transmitting a pressure waveform from the blood vessel, from which it is derived, to the transducer appears trivial. One simply connects a fluid-filled, non-compliant tube from the vessel to the transducer. However, when this is done, a new system is inadvertently created with a life of its own. The arrangement of fluid-filled tubing and associated stopcocks creates an ideal environment for trapping gas bubbles, whose quantity and volume vary unpredictably. This causes a second-order under-damped resonant system that is easily excited by the patient's arterial pressure waveform. This is analogous to an under-damped mass, spring, and resistance system. The mass is represented by the fluid mass in the tubing, the spring is represented by the compliance of the tubing and any trapped bubbles, and the resistance is represented by resistance to the movement of the fluid. The combination of these elements exhibits a characteristic tuning frequency, or resonance, determined by the element values. On a theoretical basis, when excited by a step function, amplification of up to 100% is possible. When this happens in the clinical arena, systolic pressures are amplified to varying degrees as high as 75-100 mm Hg. Diastolic values are usually not affected, since they represent a slower part of the pressure waveform. At high heart rates, under some conditions, falsely lower diastolic pressures may also appear. Mean pressure, however, does not change and is independent of this resonance. Although this phenomenon, called "resonant overshoot," has been reported in the literature for more than 70 years, solutions that consistently work are as yet unavailable. Such techniques as filtering and gas debubbling do not properly address this issue. It is not unusual to review invasive pressure waveforms in an intensive care unit and find that more than 50% of the systolic readings are suspect. The problem is twofold. First, the left ventricular rate of pressure increase (dp/dt) is crucial to the way the second-order tubing system is excited. Second, the resonant frequency of the tubing system changes as bubbles are added and removed and as temperature variations cause the bubbles to shift in volume. The resonant frequency cannot be sufficiently determined to apply an inverse filter to correct the resonance of the tubing system. Although the pressure waveform may contain obvious markers of overshoot (e.g., additional diastolic notches), this is not always the case. Identification of a suspect waveform containing systolic overshoot remains difficult.

This is a direct example of the interaction of medical devices (the transducer and its tubing set) that is often ignored to the possible detriment of the patient. No contraindications are mentioned in information insert for the tubing set that warn against relying on the systolic pressure measurement to diagnose or treat the patient. If the systolic reading, in the presence of serious resonant overshoot, is used to titrate a vasoactive drug that is controlling the patient's blood pressure, changes in the tubing environment could cause the clinician to make incorrect adjustments that could result in lower or higher patient blood pressure than desired.

MRI Interactions

Magnetic resonance imaging (MRI) systems pose a host of potential problems when used with medical devices. The powerful static and dynamic magnetic fields required to image

the patient, high power radio frequencies, and the sensitivity of the MRI detection system to radio frequencies from other devices, provide ample opportunities for troublesome interaction. In anticipation of this possibility, most MRI procedures have been contraindicated for patients with in-dwelling pacemakers due to their metallic wires.

Fundamentally, the MRI magnetics can physically displace metallic objects that are near, implanted, or attached to the patient. There have been reports of surrounding object becoming projectiles, with the displacement of aneurysm clips leading to the deaths of patients undergoing an MRI. MRIs also cause wires in devices in, on, or near the patient to overheat. Sufficient energy can be coupled with the MRI high power radio frequency generator and create currents in nearby wires. The quantity of that energy depends on a number of factors, including the wire length and its proximity to the patient. In any event, the patient or someone else must remove the additional thermal burden. This has led to patient burns in a number of instances. In addition, wires moving through the static magnetic field as the patient is moved into the magnet will also generate voltages that can interfere with the proper operation of medical devices. Special considerations must be given to wires that may enter the MRI in the process of monitoring or providing life support to the patient (e.g., ECG lead wires, pulse oximeters, or ventilators).

The increasing use of automated, implantable cardiac defibrillators (AICDs) and pacemakers in the population presents a host of potential interaction issues. Although patients with these implants were initially excluded from MRI procedures, newer devices and lower magnetic field strength MRIs permit this usage albeit with caution.

Conclusions

The explosive growth of wireless devices, such as cellular phones and wireless access points increases the potential for interference with medical devices. The literature contains ample evidence for and warnings of these effects. However, comprehensive solutions remain wanting. In addition, the proliferation of automated external defibrillators (AEDs) in the nonhospital setting raises concerns. Will an AED recognize a fibrillating heart in the presence of an implanted pacemaker? Will the discharge of an external defibrillator have an adverse effect on an implanted device and its lead wire system?

The previously mentioned examples indicate how certain types of medical devices can interact in unexpected though not unexplainable ways. The combination of instruments or accessories was not unusual or contraindicated by the manufacturers involved. The technologies that conflict are often assembled as a natural extension of improved diagnostic and therapeutic capability, but interactions are difficult to assess and problems are difficult to predict prior to their actual occurrence. As medical instruments and the environments in which they are used continue to upgrade with new technologies, it will be necessary to analyze and to understand their fundamental aspects in order to anticipate conflicts.

Single-Use Injection Devices

Michael Cheng

Health Technology Management
Ottawa, Ontario, Canada

This chapter details the safety aspects of needles and syringes—medical devices used for injecting medications into the human body and withdrawing fluid from the body. Although the chapter focuses on developing countries, many aspects also apply to industrialized countries.

The majority of injection devices are now produced for single use. Safety problems associated with the use of needles and syringes include infections caused by the reuse of contaminated devices and accidental pricks by needles (needle sticks). Pricks by contaminated needles also lead to infections. The serious impact of injection safety in global health has led to an active group called the Safe Injection Global Network (SIGN, www.injectionsafety.org) and a SIGN Internet forum (e-mail: sign@uq.net.au).

This chapter describes technical reasons not to reuse devices, auto-disable syringes to prevent reuse, safety boxes to contain sharps immediately after use, and the ultimate disposal of used sharps. The life cycle management concept proposed for major medical equipment is applied to injection devices to ensure safety in health program planning and delivery. (See Chapter 31.)

Injections and Safety

Injections are one of the most common health care procedures. Between 12 billion and 16 billion injections are administered worldwide each year. Most injections (90% to 95%) are given for therapeutic purposes and are often unnecessary. About 5% of injections are given for immunizations.

In developing countries, often because of insufficient number of injection equipment or inaccessibility to more (see injection equipment security details following) up to two-thirds of the injections in some countries are reported to be unsafe. Although immunization injections are thought to be safer than therapeutic injections, nearly 30% of immunization injections are still considered to be unsafe. Unsafe injections are responsible for millions of cases of Hepatitis B and C and an estimated 250,000 cases of HIV annually (WHO, 2000).

An injection is considered safe when it does no harm to the recipient, does not expose the health care worker to any risk of infection, and does not result in waste that is dangerous to the community or harmful to the environment.

In many developing countries and some sectors of developed countries, the reuse of injection equipment without effective sterilization may cause cross-infection. Used and often contaminated sharps (i.e., needles or syringes) are often handled in a way that exposes health care workers to needle-stick injuries. Unsafe management and improper disposal of sharps waste can also cause contamination. Sharps waste is often carelessly thrown away where waste pickers and other people can be pricked and infected.

Preventing the Reuse of Single-Use Injection Equipment

The reuse of single-use medical devices is a worldwide problem. In industrialized countries, the reprocessing and reuse of medical devices for a range of applications has raised serious concerns, and regulatory agencies are establishing measures to control syringe and needle reuse. In the United States, the Food and Drug Administration (FDA) now requires the reprocessing of a single-use device to follow the same regulatory requirements as those followed by the original manufacturer of the device. In developing countries, international health agencies find the reuse of injection equipment to be a major contributor in the spread of hepatitis, HIV, and other infections. In some regions, up to 75% of single-use syringes have been reused.

Manufacturers design devices that are labelled “single-use” with the intention that they will not be reused. The technical reasons against reuse include the following:

- Devices may not be taken apart for proper cleaning.
- Single-use devices may not be properly resterilized.
- The mechanical integrity and/or functionality of some single-use devices may not stand up to rigorous reprocessing.
- The cleaning chemicals or sterilizing agents could affect the reprocessed devices, the medication, or the patient.

Sterility, functionality, and possible hazards caused by chemical reactions after reprocessing are important issues.

Most disposable injection syringes are made of plastics that can not withstand high-temperature sterilization. With ethylene oxide gas sterilization, the bio-burden after syringe use varies a great deal from syringe to syringe, which renders reliable resterilization impractical. Other points of concern include the invasive needle that critically contacts blood, the piston rubber seal, and the lubricant, each of which could harbor pathogens. In addition, the deformity of the needle after use is likely to degrade its functionality. The risks of infection associated with the reuse of single-use injection equipment are extremely high. The seriousness of the spread of diseases caused by the reuse of single use injection equipment led to a WHO-UNICEF-UNFPA joint statement on the use of auto-disable (AD) syringes in immunization services (<http://www.injectionsafety.org/>).

The AD syringe (PATH, 2000) has a built-in mechanism that is designed to give a single dose of vaccine, after which the syringe is permanently locked or disabled. Such a mechanism prevents the reuse of contaminated syringes and needles, and eliminates their unauthorized packaging and resale. Currently, many types of AD syringes are commercially available. Increasingly, AD syringes are used in therapeutic and other injections. In many models, it is essential to completely eject the medication in the syringe in order to render the syringe nonreusable.

Preventing Sharps Injuries

To avoid needle-stick injury after an injection, the used needle should be immediately deposited into a safety box or container to prevent direct access, not recapped. Safety boxes must be made of puncture-proof material. While single-use syringes and needles should never be reused, it is possible to consider the recycling of safety boxes. However, special boxes and decontamination procedure must be strictly followed. (See <http://www.noharm.org/>.)

The use of safety boxes should not be regarded as the end of the safe disposal of used needles or syringes. Final appropriate and safe disposal requires systematic considerations.

Ultimate Safe and Appropriate Disposal of Sharps Waste

The ultimate disposal of injection equipment can be part of the institution-wide health-waste disposal system. Safety boxes containing used sharps must be disposed in a manner that is consistent with protecting the environment.

The Appendix on p.253 provides a comparison of various methods for the disposal of sharps waste. It should be noted that each method has its strengths and weaknesses, and no single waste disposal solution is best. Health care facility administrators must identify the most appropriate disposal technologies depending on the local regulations, the size of health care facilities, the location, (e.g., urban versus rural) and the availability of construction material for building incinerators or pits or to encapsulate waste. Geographical factors are also important and include the ease of access to final disposal sites and the nature of the soil where the health facility is located (e.g., sandy, muddy, flood-prone, or rocky ground.)

Some of the current options, such as incineration, are considered unacceptable by a number of environmentalist groups. Health waste disposals are important issues and

Table 61-1 Life Cycle Management Applied to Injection Equipment

<i>Essential element for major equipment (life cycle management)</i>	<i>Injection equipment application</i>	<i>SIGN Toolbox references* (8 May 2003)</i>
Planning	Situational and needs assessment Qualified health care workers? Real need for medication? Oral alternative? Behavioral change? Injection equipment security Adequate storage? Disposal: Safety boxes Disposal facilities Communication strategies	1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, 2.5, 2.6, 3.1
Acquisition	Procurement steps, price negotiation Quality assurance criteria	1.6
Delivery	Shipment damage?	1.6
Incoming inspection	Specified goods?	
Inventory and documentation	Master inventory Distribution records	1.6
Commissioning	Proper storage and safeguard Good distribution practices to health facilities	
Training of users	Appropriate use Safe use	1.2, 1.4, 1.5, 1.8, 2.1, 2.2, 2.3, 2.4, 2.6, 2.7
Monitoring of use and performance	Monitor risks, such as: Breakage Needle-stick Incomplete ejection to disable syringe Splash of blood or medication Reuse Safety boxes for used sharps	
Maintenance	Adequate resupply Injection equipment security Maintain number matched to medications	1.1, 1.6
Replacement disposal	Appropriate disposal Safe disposal	2.5, 2.7

alternative technologies are being researched and developed. (See <http://www.noharm.org/>.)

Application of Life Cycle Management

In health projects such as an immunization program or any therapeutic program involving injections, ensuring product quality of vaccines and injection equipment is not enough to ensure safety. All aspects of immunization, including product quality, storage, handling, administration of injection, and disposal must be considered. In fact, the life cycle management concept developed for major medical equipment can be useful here. This concept calls for the inclusion of other essential elements for good management. (See Chapter 31.) For example, introducing an injection safety component at the planning phase of health projects involving injections is a proactive way to ensure safety. The different essential elements in the life cycle management concepts, from planning to disposal, can apply.

In Table 61-1, major management items are cross-referenced to various publications available in the Toolbox of the Safe Injection Global Network (SIGN). These publications are neither standard nor exhaustive, but they contain detailed descriptions of the management items to illustrate the applicability of the concepts.

Planning for safe disposal in various countries includes assessment of the disposal situation in each country. Once the supply of injection equipment has been determined, injection equipment security, safety boxes, and disposal facilities are considered as follows:

- Injection equipment security. Matching the quantity of medications or vaccines with the supply of injection equipment to ensure enough devices for all medications or vaccines without the need to reuse equipment. The lack of access to safe injection equipment frequently leads to reuse.

- Safety boxes. Sufficient number of safety boxes must be supplied to contain the sharps immediately after use. The use of the safety box is not the end of the disposal responsibility but a part of the safe use phase.
- Final disposal. The means and facilities for the final disposal of the safety boxes containing used sharps must be determined at the planning stage. The disposal procedures must ensure personal safety and protect the environment.

Discussion

The life cycle management table provides a simple, one-page checklist for key items of the whole management system. (See Table 61-1.) Details of key items that are specific to a certain health program or project can be added for customized consultation. This one-page picture also allows any health worker to see the relevance of his or her role in the overall system, an important first step toward increasing the system efficiency and effectiveness.

The life cycle management approach, originally developed for major medical equipment, also applies to nonmajor, but essential, medical devices and may be extended to additional devices.
